SUPPLEMENT  
TO THE  
CYCLOPÆDIA OF INDIA  
AND OF  
Eastern and Southern Asia.

(The abbreviations C. of I. and of C. of I. S. signify the Cyclopædia of India and Cyclopædia of India Supplement).

ABELMOSCHUS ESCULENTUS.

(1) ABELIA RUPESTRIS. This was amongst the plants which were nearly destroyed in the fight between Mr. Fortune's servant and the natives. There were also several fine roots of *Campanula grandiflora*, which grows wild amongst these hills, and this new species of *Abelia* (*Abelia rupestris*). Both ultimately arrived safe in England and are now in the garden of the Horticultural Society at Chiswick.—*Fortune's Wanderings*, page 28.

(2) ABELMOSCHUS ESCULENTUS.

This plant is remarkable for the similarity of its name to the vegetable called Ochra by the Greeks, but which has not been ascertained by botanists. The names by which this produce of the New World is distinguished in the works of Marcgrave and Piso are Quingambo and Quigombo, and in the later works by that of Gombo and Gombaut or Gombeau. It is possible, therefore, that a classical name which was not otherwise engaged may have been applied to a new vegetable, and, as has been the case in many instances, without any attempt being made to identify the plant named with that which had been described by classical authors. This plant is the *Hibiscus esculentus* of authors.—*English Cyclopædia*, page 60. The okra plant of the Southern States of America, as universally abounds in the Tenasserim Provinces, and all over the East, as it does in the West Indies.—*Mason. Abelmoschus Esculentus*, known in America as the Okra or Gumbo, is much cultivated there. In Louisiana, Gumbo soup is an epicurean dish. The ripe seed if allowed a sufficient age before using and carefully parched can with difficulty be distinguished from genuine coffee.—*Ag. Rep. from American*

ABIES.

(3) ABELMOSCHUS MOSCHATUS.

(MUSK HIBISCUS). *Syn.* *Hibiscus Abelmoschus*. Dancer states the seeds to be emeticus, but Dr. O'Shaughnessy had not found this to be the case in his experiments.—*O'Shaughnessy*, page 217. One of the most gaudy flowering shrubs in Tenasserim, is this musk plant, whose large yellow blossoms with blood colored eyes are sometimes seen bedecking European grounds, and whose seeds have been said to be an antidote to snake bites.—*Mason*.

(4) ABIES. The Fir. *Abies*, in Botany, forms a genus of trees of the Coniferous tribe, well known for the valuable timber which is produced by many of the species. It was formerly considered a part of the genus *Pinus*; but modern botanists have made it a distinct genus. The English appellation is the saxon *furh-wudu*, fir-wood. From *Pinus* (*Pine-Tree*), *Abies* (the Fir-Tree) is obviously distinguished by its more pyramidal form, and by its leaves arising singly from around the stem, not by twos or threes or a greater number, from out of a membranous shrivelling sheath, as well as by the characters in the fructification above described. Its species form four natural tribes, of the first of which, the *Silver Fir* may be taken as the representative; of the second, the *Norway Spruce*; of the third, the *Larch*; and of the fourth, the *Cedar of Lebanon*. The genus of resinous plants called *Abies*, comprehend many forest trees of great importance; some of them, such as the *Larch*, the *Norway Spruce*, the *Silver Fir*, and the *Balm of Gilead*, are raised in the English nurseries, annually in the open ground, in large quantities for the supply of plantations there; others, such as the *Cedar of Lebanon* and the *Douglas Fir*, are

care, being usually kept in pots until they are finally committed to the earth in the situation they may be subsequently destined to occupy. All the species are propagated by seeds; they may also be propagated both by inarching and by cuttings; but it is found that plants so obtained are either very shortlived or stunted, unhealthy, and incapable of becoming vigorous trees. In some of the species, as the Balm of Gilead and the silver Fir, the scales of the cones readily separate from their axis, so as to render the extraction of the seeds a simple and easy operation; but in others such as the Larch and the Spruce Fir, the scales will neither separate nor open: in such cases it is necessary to dry the cones as much as possible, then to split them by means of an instrument passed up their axis and afterwards to thresh the portions so separated till the seeds can be sifted out. Like other resinous seeds these are perishable unless sown within a few months after the cones have been gathered; they will however, keep much longer in the cone than if separated; wherefore, they should always be imported in that state. None of the firs should be transplanted at a height exceeding three feet, for the reason last mentioned; and the Larch is the only kind that will remove advantageously even at this size. The spruce and its allied species may be removed more successfully when from a foot and a half to two feet high. To this there is no other exception than that of plants that have been constantly reared in pots, as the Cedar of Lebanon; these may be safely removed at any size, if the transplantation is carefully attended to, because their roots are uninjured in the operation. It should however be remembered, in finally planting out firs which have been always kept in pots, that it is absolutely necessary that their roots should be spread out among the earth as much as may be practicable without straining or breaking them; because, while in pots, they necessarily acquire a spiral direction, which they will not afterwards lose unless it is destroyed at the period of final transplantation; and, if they do not lose it, they are apt to be blown over by high winds, on account of their roots not having penetrated into the earth far enough in a horizontal direction to form the requisite stay to support the trunk and head. Where great importance is attached to the raising of the seeds of rare species of fir, it has been found a very beneficial practice to place them between two turfs placed root to root, the one upon the other, and to watch them till the seeds begin to sprout; they are then to be sown in the usual way, when every seed will usually succeed. No trees are more impatient of pruning than these. They exude, when wounded, so large a quantity of their resinous sap as to become weakened even by a few incisions; and if they have suffered many, they are long

before they recover from the effects. So great is their symmetry, and so uniformly will be their branches from under favourable circumstances, that it will rarely happen that a necessity for the use of the pruning-knife can arise. The great rule to be observed in their management is to allow them ample room for the extension of their branches; if this is attended to, their beauty is not only ensured but the rate at which they will form their timber will be a full recompense for the space they may occupy.—*Eng. Cyc.* page 15. All the species of Abies will grow in England, where the soil is light enough to suit them, particularly *A. Deodara*, the Cedar of India, *A. Cedrus*, the Cedar of Lebanon, and *A. Larix*, the common Larch, together with *A. balsamea*, the Balm of Gilead, *A. picea* the Silver-Fir, and *A. Webbiana*, the Silver-Fir of the Himalaya Mountains. The Cedar of Lebanon will grow well in a swamp.—*Eng. Cyc.*

The Pines of Sikkim received from Dr. Hooker frequent notices. He says that Abies Brunoniana, A. Smithiana, and A. Webbiana, with Larix Griffithii are the only pines whose woods are considered very useful; and it is a curious circumstance that, there, none produce any quantity of resin, turpentine, or pitch; which may perhaps be accounted for by the humidity of the climate.—*Fol. ii. p. 41.* At Choongtam in Sikkim, the yew appears at 700 feet, whilst, on the outer ranges (as of Tonglo), it is only found at 9,500 to 10,000 feet, and whereas on Tonglo it forms an immense tall tree, with long sparse branches and slender drooping twigs, growing amongst gigantic magnolias and oaks, at Choongtam it is small and rigid, and much resembling in appearance the English churchyard yew. At 8000 feet the Abies Brunoniana is found, a tree quite unknown further south. But neither the larch nor the *Abies Smithiana* (Khutrow) accompanied it. The yew spreads east from Kashmir to the Assam Himalaya and the Khasia mountains; and the Japan, Philippine Island, Mexican, and other both American yews, belong to the same widely diffused species. In the Khasia (its most southern district) it is found as low as 5000 feet above the Sea level. In descending from Nango in East Nepal, Dr. Hooker passed at first through rhododendron and juniper, then through black silver fir (*Abies Webbiana*), and below that, near the river, he came to the Himalayan larch; a tree quite unknown, except from a notice in the journals of Mr. Griffith, who found it in Bhotan. It is a small tree, twenty to forty feet high, perfectly similar in general characters to a European larch but with larger cones, which are erect upon the very long, pensive, whip-like branches. He adds, its leaves, now red, were falling, and covering the rocky ground on which it grew, scattered amongst other trees; It is called "Saar" by the Lep-

## ABIES BRUNONIANA.

ches and Cis-Himalayan Tibetans, and "Boingga-sella" by the Nepalese, who say it is found as far west as the heads of the Cusi river: it does not inhabit Central or West Nepal, nor the North-West Himalaya. The distribution of the Himalayan pines is very remarkable. The Deodar has not been seen east of Nepal, nor the *Pinus Gerardiana*, *Cupressus torulosa*, or *Juniperus communis*. On the other hand, *Podocarpus* is confined to the east of Katmandoo. *Abies Brunoniana* does not occur west of the Gogra, nor the larch west of the Cusi, nor funeral cypress (an introduced plant however) west of the Teesta (in Sikkim). Of the twelve Sikkim and Bhotan *Coniferae* (including yew, juniper, and *Podocarpus*) eight are common to the North-west Himalaya (west of Nepal), and four are not: of the thirteen natives of the north-west provinces, again, only five are not found in Sikkim, and, he adds, I have given their names below, because they show how European the absent ones are, either specifically or in affinity. I have stated that the Deodar is possibly a variety of the Cedar of Lebanon. This is now a prevalent opinion, which is strengthened by the fact that so many more Himalayan plants are now ascertained to be European than had been supposed before they were compared with European specimens; such are the yew, *Juniperus communis*, *Berberis vulgaris*, *Quercus Bal-lota*, *Populus alba* and *Euphratica*, &c. The cones of the Deodar are identical with those of the Cedar of Lebanon: the Deodar has, generally longer and more pale bluish leaves and weeping branches, but these characters seem to be unusually developed in English gardens; for several gentlemen, well acquainted with the Deodar at Simla when asked to point it out in the Kew gardens, have indicated the Cedar of Lebanon, and when shown the Deodar, declare that they never saw that plant in the Himalaya. —Hooker, *Him. Jour.*

(5) ABIES ARARAGI (SIEBOLD). Wood brown; used for various domestic purposes. —Eng. Cyc.

(6) ABIES BRUNONIANA, Semadong, the deciduous Silver Fir (*Pinus Brunoniana*, Wallich; *P. dumosa*, Lambert). Leaves flat, all turned one way, serrulate towards the points, covered beneath with a milk-white bloom. Cones terminal, erect, ovate, blunt, very small, with lax, ovate, very blunt scales.—Found in the northern parts of India in the provinces of Nepaul, Bootan, and Gossain Than. It is a tree 70 or 80 feet high, with a clear trunk of from 15 to 20 feet, and a spreading very branchy head. The wood is of bad quality, being liable to warp.—Eng. Cyc. This species is repeatedly noticed by Dr. Hooker; at one place he says that the wood of *Abies Brunoniana*

## ABIES DEODARA.

("Semadoong") is like the others in appearance but is not durable; its bark is however very useful. Stacks of different sorts of pine-wood were stored for export to Tibet, all thatched with the bark of *Abies Brunoniana*. In the dense and gigantic forest of *Abies Brunoniana* and silver fir, he measured one of the former trees, and found it twenty-eight feet in girth.—*Him. Jour.*

(7) ABIES CEDRUS, the Cedar of Lebanon Fir (*Pinus Cedrus*, Linnæus and Lambert). Leaves clustered, evergreen. Cones oblong, very obtuse, erect, with broad closely packed scales, which are a little thickened at the margin. Mount Lebanon and the range of Taurus are the native spots of this most stately and magnificent tree, which compensates for its want of height by its huge wide spreading arms, each of which is almost a tree in itself. According to Labillardière, a French traveller in Syria, the largest of those now remaining on Lebanon is at least nine feet in diameter. The trees are held in great veneration, and a holiday is set apart for the Feast of Cedars. Its growth is far from being so low as some imagine; on the contrary, the observations of those who have cultivated it with care prove that it will vie in rapidity of growth with almost any forest tree. Cedar wood has the reputation of being indestructible; instances have been named of its having been taken from buildings uninjured after a lapse of two thousand years. But it appears highly probable, from some interesting observations made at Tangier by Mr. Drummond, that the indestructible cedar wood was the beautiful, hard, deep-brown timber of *Thuja articulata*, the Sandarac Tree. The wood of *Abies cedrus* produces deal of very indifferent quality.—Eng. Cyc.

(8) ABIES DEODARA, the Sacred Indian Fir (*Pinus Deodara*, Lambert). Leaves evergreen, in clusters, acute, triangular, stiff. Cones growing in pairs, stalked, oval, obtuse, erect; the scales closely packed, very broad, and nearly even at the margin. It is a native of the mountains of Hindustan, near the town of Rohilkund, on the mountains of Nepaul and Tibet, at a height of 10,000 or 12,000 feet, and also in the woods of Almora. It is a large tree, with a trunk about four feet in diameter, resembling the Cedar of Lebanon, from which it differs in having its cones upon stalks, and its leaves longer and more distinctly three-sided, and also in the quality of its timber. The Hindoos are said to call it the Devadara, or God Tree, and hold it in a sort of veneration. Its wood is extremely durable, and so resinous that laths made of it are used for candles. Spars of it have been taken out of Indian temples, known to have been erected from 200 to 400 years, uninjured except in those parts which originally were

## ABIES WEBBIANA.

sap-wood. This tree has been extensively cultivated in England, and seems to be realising the favourable anticipations which were formed on its first introduction.—*Eng. Cyc.* See CEDAR DEODAR.

(9) ABIES KEMPFFERI (*Pinus Kämpferi*, Lambert). A native of Japan; found wild upon the mountains of Fako.

(10) ABIES MOMI (Siebold). Found in Japan. Its wood is in great estimation for its whiteness and fine grain.—*Eng. Cyc.*

(11) ABIES SMITHIANA, Seh, the Indian Silver Fir (*Pinus Smithiana*, Wallich). Leaves slender, four-cornered, whitish beneath, a little turned towards one side dark green, from one inch to one and a half long. Cones from four to six inches in length, erect, ovate-oblong, with obovate, rounded, even scales. A native of the slopes of the Himalaya Mountains. It is a tree of enormous size, with nearly opposite branches, covered with short down, and so arranged as to form generally two rows.—*Eng. Cyc.* This plant is repeatedly noticed by Dr. Hooker: at one place, he tells us that the spruce, (*Abies Smithiana*, "Seh") has white wood, which is employed for posts and beams. At another, he mentions that the beautiful Deodar was seen towering above the other trees, and, although all the specimens were comparatively young, they were yet striking and graceful. Near it was the *Abies Smithiana*. It had a dark and sombre appearance, yet it was peculiarly graceful, owing to its symmetrical form and somewhat pendulous habit. Again, he says, that towards Lamtang, in Sikkim the path left the river, and passed through a wood of *Abies Smithiana*. It is also called *A. Khutrow* and *Morinda*. Dr. Hooker had not before seen this tree in the Himalaya: it is a spruce fir, much resembling the Norway spruce in general appearance, but with longer pendulous branches. The wood is white, and considered indifferent, though readily cleft into planks.—*Hooker, Him. Jour.*

(12) ABIES THUNBERGII (*Pinus Thunbergii*, Lambert). A scarce plant in Japan.

(13) ABIES TORANO (Siebold)

(14) ABIES WEBBIANA, Webb's Fir (*Pinus Webbiana*, Wallich and Lambert; *Pinus spectabilis*, Lambert). Leaves linear, solitary, flat, all-spreading, and turned one way, silvery-white beneath, with a deep notch at the extremity. Cones oblong, erect, obtuse, with very broad, rounded, even scales. According to the account of Captain Webb, who first discovered it, this remarkable species attains the height of 10 or 20 feet, with a diameter near the ground of 3 or 4 feet. Its wood seems to be valuable. From what has been reported of its general appearance, it is probably one of the most interesting species that has yet been discovered. Inhabiting the colder regions

## ACACIA (RHEONJ).

of northern India, and found among plants which are more Siberian in their character than Indian, there can be no reasonable doubt of its being well able to withstand the rigour of the winters of England.—*Eng. Cyc.* Dr. Hooker tells us that, at Choongtam, the *Abies Webbiana* attains thirty-five feet in girth, with a trunk unbranched for forty feet.—*Hooker, Him. Jour.* As the subject of fire-wood is of every day interest to the traveller in these regions, he mentions that the rhododendron woods afford poor fires; juniper burns the brightest, and with least smoke, *Abies Webbiana*, though emitting much smoke, gives a cheerful fire far superior to larch, spruce, or *Abies Brunoniina*. At Dorjiling, oak is the common fuel; alder is also good. Chestnut is invariably used for blacksmith's charcoal, Magnolia has a disagreeable odour, and laurel burns very badly. The silver fir (*Abies Webbiana*, Dunshing) also splits well; it is white, soft, and highly prized for durability. The larch of Northern Asia (*Larix Europæan*) is said to produce a pungent, smoke, which Dr. Hooker never observed to be the case with the Sikkim species.—*Hooker, Him. Jour.*

(15) ABRESHAM, White silk, cut into very minute pieces; is used in Ajmere to remedy impotence: four tolas for one rupee.—*Genl. Med. Top. page 126.*

(16) ABROMA (from *a* and *βρῶμα* 'not fit for food,' in opposition to *Theobroma*, 'food for gods'), a genus of plants belonging to the natural order *Byttneriaceæ*. The species consist of small trees, with hairy lobed leaves and extra-axillary or terminal few-flowered peduncles at the tops of the branches.—*Eng. Cyc. p. 17.*

(17) ABRUS (from *αβρός*, soft), a genus of plants belonging to the papilionaceous division of the order *Leguminosæ*. The calyx is bluntly 4 lobed, with the upper lobe broadest. The legume is oblong, compressed, and 4-6 seeded. There is but one species, *A. precatorius*.—*Eng. Cyc.*

(18) ACACIA (Choukur) A species of silk tree Acacia. Choukur. *Hind.* A common low tree in many parts of Rajwarra. The flowers are long, cylindrical, one-half yellow, the other half bright pink and not mutable, the colored stamina exactly resembles tufts of floss silk: the wood is put to no use.—*Genl. Med. Top.*

(19) ACACIA (REWA) SACRED ACACIA.  
Rewa, *HIND.*

A large tree common in Rajwarra, sacred to the Matajee, around whose shrines groves of this tree are commonly found. The wood is hard, dark colored, and durable, but only the decayed trees are used.—*Genl. Med. Top.*

(20) ACACIA (RHEONJ). TRAVELLER'S ACACIA.

Rheonj, *HIND.*

A very common tree in particular parts of

## ACACIA SCANDENS.

Rajwarra, upon which travellers at certain parts of the roads suspend shreds of their cloths (as in other parts of India). To the extremities of the young branches are suspended innumerable masses of exuded sap of large size.—*Genl. Med. Top. p. 197.*

(21) **ACACIA ARABICA.** For Ordnance purposes, if properly seasoned, it would be found equal to any timber in use. The best mode of seasoning is to immerse the log when felled in a mud pit for twelve months and then to remove it to a drier spot till brought into use. It rarely exceeds 18 inches in diameter and is always crooked. Cattle eat the seeds, which if burnt yield the moochies a good black for paint.—*Rohde, M.S.S.*

(22) **ACACIA CATECHU.** *Willd.* A tree from 15 to 20, but sometimes 30 feet high, with hard and heavy wood, of which the interior is of a dark red or brownish colour, and the sap-wood white. Branches with stipulary thorns. Leaves bipinnate. Pinnæ 10 to 15 pairs. Leaflets 30 to 50 pairs; linear oblong, unequal and auricled on the lower side at the base; petiole angular, often armed in arid situations with a row of prickles on the under side, with one large urceolate gland below the lowest pair of pinnæ and smaller ones between the 2 to 4 terminal ones. Inflorescence a spike, 1 to 3 together in the axillæ of the leaves. Flowers numerous white. Calyx downy, 5-fid. Petals united into 5-fid corolla. Stamens numerous, distinct, double the length of the corolla. Ovary shortly stipitate. Style the length of the stamens. Legumes straight, thin and flat and smooth, with about 4—6 seeds. A native of the jungles and low hills of many parts of India—*Roxb. Corom. Plants, 11, t. 175.* quoted by *Royle, p. 350.*

### (23) ACACIA CINEREA.

• Ash coloured mimosa,	Werdil, HIND.
Eng.	Vedatil, TAM.
Vellatooroo, TEL.	

### (24) ACACIA EDULA. ESCULENT ACACIA.

Khôra. HIND.

A very common large tree in Rajwarra; the long slender pods are very sweet and pleasant food cooked: for this purpose, they are universally gathered by the poor wherever procurable and eaten both fresh and dried. The wood is very hard but the tree is not cut down.

### (25) ACACIA FERRUGINEA.

Rusty mimosa wood,	Keekur safeed, HIND.
Eng.	Vil velum, TAM.
Tella tooma, TEL.	

### (26) ACACIA SCANDENS: CLIMBING MIMOSA.

Gila. HIND.

A large creeper running over trees in the Kotah jungles, where the stems of this plant often in size and form resemble ship cables.—*Genl. Med. Top. p. 197.*

## ACANTHOPTERYGII.

### (27) ACACIA SERISSA,

• Mimosa Serissa	Vapamaram TAM.
Derisana, TEL.	Katoo vayh, Vriksha,
Serissa, BENG.	CAN.

This tree is very common in every part of India; all soils and situations seem to please it equally: it grows to be a pretty large tree but with a short thick trunk covered with ash-coloured bark. It has a very extensive but thin head. Flowering time the hot and rainy season, the greatest part of its leaves drop during the cold season. The wood of this tree is serviceable. The flowers are very fragrant, large masses of very pure gum are occasionally found upon it.—*Roxb.* This tree is occasionally found in avenues for which it is not well adopted, as it remains long without leaves, at the commencement of the hot season. The wood used to be employed for mallets wherewith to beat cloth when making it up in bales for the European market, it is also used for large screws and for fellers. Mr. Rohde discovered that prejudices exist to have induced some to under-value this wood, it is said to be unlucky and workman therefore decry it.—*Rohde, M.S.S.*

Seris grows at Ajmeer and abundant in Kotah: it is a beautiful tree with very fragrant flowers: the wood is valuable.—*Gen. Med. Top. p. 197.*

(28) **ACACIA STIPULATA**, is mentioned by Mr. Mason, as one of the trees of the Tenasserim Provinces. The fragrant acacia is indigenous in the Provinces, and is said to yield "a hard and strong timber." The largest timber tree belonging to the genus with which he was acquainted, is a common forest tree, and from the character of the genus would no doubt furnish valuable timber.

(29) **ACACIA SPECIOSA** *Syn. Mimosa Sirrisa.* This tree is easily recognised by its white flowers and long stamens; Wight says it attains a large size and is a common tree, frequent by road sides on account of the shade its large head affords. The wood is white, at least as compared with the kurry vaugay, but is very strong and durable: in trials it bore 563 lbs.—*Wight.*

(30) **ACALEPHÆ** (from ἀκαλήφη, a nettle), *Sea Nettles*, a class of marine invertebrate animals, belonging to the sub-kingdom *Radiata*. It is now made to include a large number of animals, of which the genus *Medusa* of Linnaeus, may be taken as a type.—*Eng. Cyc. p. 28.*

(31) **ACANTHOPTERYGII** (from ἀκανθα, a thorn, and πτερυξ, a wing), in zoology, one of the three primary divisions, or natural orders, of fishes. The fishes are divided into three orders, the *Chondropterygii* (from χόνδρος, cartilage, and πτερυξ, a wing or fin), or cartilaginous fishes, without a solid bony skeleton; *Acanthopterygii*, fishes, having bony skeletons with prickly spinous process in the dorsal fins; and *Malacopterygii*

(μαλακός, soft, and πτέρυξ, a wing), fishes, with bony skeletons indeed, but with soft articulated radii in the dorsal fins. These divisions were first employed by Willoughby and Ray. Cuvier divides the Acanthopterygious fishes into fifteen natural families, which he calls after the names of their typical or most common genera.—*Eng. Cyc.*

1. *Peroidæ*, including the common Perch, the Sea-Perch, the Barber of the Mediterranean, the Weevers, the Stargazers, and the Sea Pike.

2. *Triglidæ*, which include the Gurnards, the Flying-Fishes, the Bull Heads, the Miller's Thumb, and the sticklebacks.

3. *Scianidæ*, which include the Maigres, the Stone-Perch, the Drum-heads, the Red-Throats, and a number of other fishes less known.

4. *Sparidæ*, including the Sea-Breams, the Spanish Bream, the Gilt-Head, and Black Bream.

5. *Menidæ*, a small family whose species are not much known.

6. *Squamipennes*, including the Chætodons and other curious fishes, as the Coachmen, the Horsemen, and others.

7. *Scomberidæ* includes the Mackerel, the Tunnies, the Sword-Fishes, the Pilot, Pilot-Fishes the John Dory, and the king-fish.

8. *Tandidæ*, including the Scabbard-Fish, the Hair-Tail, Red-Band-Fish, and others.

9. *Theutyes*, including the Lancet-Fishes and some other genera remarkable for their powerful cutting spines.

10. *Anabadæ*, include the Climbing Perch and other allied freshwater fishes.

11. *Mugilidæ*, include the Gray Mullet, the Ramando of Nice, and some others.

12. *Gobioidæ*, include the Blennies, the Gobies or Sea Gudgeons, and the Dragonet.

13. *Lophiadæ*, include the Anglers, Fishing Frog, or Sea-Devil, and the Frog-Fishes.

14. *Labridæ*, include the Wrasses, or Rock-Fishes, the 'Old Wives of the Sea,' the Captains, and the Scarus.

15. *Fistularidæ*, include the Pipe-Mouths, the Snipe-Fish, the Sea-Trumpet, or Bellows-Fish.—*Eng. Cyc.* page 50.

(32) ACANTHUS. In modern botany *Acanthus* is a genus of herbaceous plants found in the south of Europe, Asia Minor and India, belonging to the natural order *Acanthaceæ*.—*Engl. Cyc.*

(33) ACANTHACEÆ, an order of plants belonging to the Monopetalous division of *Dicotyledons*. Its type is the genus *Acanthus*. The species are herbaceous or shrubby; they are extremely common in every tropical country. Many of the species are mere weeds; others bear handsome flowers with gaudy colours, but seldom with any odour; a very small number have been occasionally employed medicinally as emollients or diuretics. The stems of all the

species emit roots very readily from their tumid articulations; on which account gardeners universally increase them by cuttings of the full-grown branches. They are always easy to cultivate provided they are not kept in too cold or too dry a situation. The annual kinds freely produce seeds, by which they are readily multiplied. The most common genera are *Justicia*, *Acanthus*, *Kueltia*, *Thunbergia*, *Barleria*, *Eranthemum*, *Larkesteria*, and *Henfreyia*. (Brown's *Prodromus Floræ Novæ Hollandiæ*; Barthing's *Ordines Naturales*; Lindley's *Introduction to the Natural System*; and Nees von Esenbeck's *Exposition*, in the third volume of Dr. Wallich's *Plantæ Asiaticæ Rariores*.)—*Eng. Cyc.*

(34) ACANTHOPHIS (from *ακανθα*, a thorn and *οφίς* a snake) in zoology, a genus of venomous serpents, allied to the vipers, but distinguished by having a single series of plates beneath the tail, except towards the very extremity where they are, in some cases, separated into two small rows. *Eng. Cyc.*

(35) ACARIDÆ, a division of *Arachnida* which comprehends the small spider like animals popularly termed Mites (*Acar*), as well as Water Mites and Ticks. Some of these are wanderers on land or in water; others are fixed upon various animals, whose blood or humours they suck, and even insinuate themselves beneath the skin, and often multiply prodigiously.

The Domestic Mite (*Acarus domesticus*, De Geer), is very commonly found in collections of insects and stuffed birds, and is exceedingly destructive to cabinets. Camphor has some effect in destroying this pest, but is not powerful enough to prevent it altogether. Moistening the specimens with a weak solution of corrosive sublimate, is said to prove an effectual preventative.

The species found in flour and on food is called *A. Farinæ*.

The Itch Mite (*Acarus Scabiei*, Fabricius, *Sarcoptes Galei*, L.) is a microscopic animal, found under the human skin in the pustules of a well known cutaneous disease. It has a remarkable suctorial apparatus, by means of which it secures its hold under the epidermis of the skin, into which it has the power of penetrating. This animal is most effectually destroyed by sulphur; and indeed this is a specific for the disease which the *Acarus* produces.—*Engl. Cyc.*

The Sugar Mite (*Acarus Saccharinum*) is found in the West Indian brown sugar of commerce. Thirty-five out of thirty-six specimens examined by the analytical Commissioners of 'The Lancet,' bought in the shops of London in 1850, were found to contain these creatures.

The Red Spider of the hot-houses of England is the *Acarus tellarius*. It is the pest of hot-houses and green-houses. Though so small as scarcely to be seen by the naked eye, its effect on plants are very obvious. These creatures live

## ACONITUM.

upon the juices of the plant which they attack, and also present the function of the leaves from being properly performed. They are best destroyed by sulphur. The mode of applying it is to sprinkle the sulphur on the hot pipes or on plates; afterwards the plants should be syringed. Other species, as *A. hortensis*, *A. holosericeus*, *A. Geniculatus*, attack various plants, and the best way of treating them is the same as the above.—*Eng. Cyc.* page 52.

### (36) ACHYRANTHES POLYGONOIDES

Tooilkeeray, TAM.  
Chenchala koor, TEL.

Soonishunna, SANS.—*Ainslie's*  
*Mat Med.* page 254.

(37) ACIDS. For making these, natives of India have peculiar formulæ: their lemons and limes give them citric and the gram plant (*Oicer arietinum*) the oxalic acid.—*Royle Arts &c. of India*, page 463.

(38) ACIDUM BENZOICUM, Benzoic Acid, though named from Benzoin, is found in other substances, which are on this account called Balsams, such as Storax, and the Balsams of Peru and of Tolui. It is also produced by the action of reagents on several vegetable substances. Indeed, it is supposed by Prof. Johnston to be produced in the balsams themselves by the action of heat or other reagents.—*Royle*.

### (39) ACONITUM HETEROPHYLLUM.

The root of this plant has been long known in Indian medicine as a tonic and aphrodisiac. Mr. Heming, Sub Assistant Surgeon of Orai, has lately brought to the notice of the authorities, a substance passing under the name of Atees, which he has found to be an invaluable febrifuge, superior in many cases in his partial estimation to Quinine. The writer adds "I first saw this substance in the form of a fine white powder with an intensely bitter taste and from which a very bitter extract may be prepared. I have since seen the root from which it is procured, it is fusiform and occurs in single pieces with one extremity broken off, the largest I have seen is not more than an inch in length, the roots are grey outside and white internally with a very bitter taste. I believe they have not yet been thoroughly analysed. The true Atees is the root of Aconitum Heterophyllum which only grows in the Himalayas and Dr. T. Thomson mentions that the root sent here by Mr. Heming agrees with Dr. Royle's of that plant; but Captain Lowther says that Atees grows chiefly in the Deccan, especially in Guzerat, whence it is conveyed to Indore. It is procurable there with difficulty for 9 rupees the seer.

The true Atees is intensely bitter, slightly astringent, and with abundant farina, which is free from any noxious quality. There is a spurious substance resembling it but by no means of the same efficacy which Dr. W. O' Shaughnessy says

## ACORACEÆ.

he has reason to believe is the dried tuber of the *Asparagus sarmentosus*.

It is to be hoped that the question of the value of the substance used by Mr. Heming and the locality from which it is derived, will be soon determined. He deserves much credit for the zeal with which he has prosecuted the subject. The dose may be considered about 1 scruple three times daily, Mr. Heming has given 30 grains as often without any bad effect. I may mention that I have cured a few cases of slight fever in the College Hospital with 2 grs. of Atees three times daily, but it is questionable whether the cure was not attributable to the purgative or emetic given in the first place.—*Ind. Ann. Med. Sci. for Apl.* 1856 page 395.

(40) ACONTIAS (from *ἀκων*, a javelin), the name of a genus of serpents established by Cuvier, for the purpose of distinguishing certain species hitherto placed with the genus *Anguis*, or common snake. This genus is characterised by the absence of all the bones which represent the extremities in the genus *Anguis*, while it retains the structure of the head common to these animals and to the lizards, and has the body similarly covered with small scales only, without the horny plates which guard its under surface in the common serpents, and protect them from injury in the various rapid motions which they perform. The species of *Acontias* seem thus to afford a link between the common snakes and true serpents. As might naturally be expected from this conformation, the progressive movements of the species of *Acontias* are very different from those of common serpents. They do not glide along the surface like these animals, but boldly carry their heads and breasts erect; and if closely pursued defend themselves, courageously, and dart with the velocity of an arrow against their assailant. Though dreaded in their native countries, because confounded with their venomous congeners, these animals are perfectly harmless, and neither possess the means nor have the desire of being injurious. They have no poison fangs, and their cheek-teeth are so small as, in some species, to be barely perceptible. Their habits are gentle; and they are so timid that they generally fly at the least noise, or, upon the slightest appearance of danger, conceal themselves (under some shrub or tuft of grass, or even bury themselves under ground when no other refuge is at hand. Other species inhabit Asia Minor, Egypt and Persia; India and China have also their *Acontias*; and the Cape of Good Hope produces a species without eyes.—*Eng. Cyc.*

(41) ACORACEÆ, Lindl. (Nov. a tribe of Orontiaceæ.) A spadix naked and closely covered with flowers. Flowers surrounded with 6 scales. Ovary 3 celled, about 5 suspended ovules in each cell. Stigmas 3 lobed. Berries

## ACOTYLEPONS.

1 seeded (Lindl). The *Acoraceæ* are now made a tribe of *Orontiaceæ* by Dr. Lindley. (Veg. King. p. 194) and are like these allied to *Araceæ* many of which secrete much secula often united with acrid principle, but as the starch may be separated by washing, as in the case of what is called Portland Sago or Arrowroot, yielded by *Arum maculatum*, so the rootstocks of several form articles of diet in different countries.

—*Eng. Cyc.*

(42) *ACORUS CALAMUS*, Linn, L. E. Rhizoma L. E. or Rootstock of common Sweet Flag *Calamus aromaticus*, E.

The *Skopos* of the Greeks, the wuj of the Arabs, and buch of the Hindoos. It has no claim to the name assigned it in the L. P.

Rhizoma thick, rather spongy, aromatic like every other part of the plant. Leaves erect, 2-3 feet high about an inch broad, of a bright green colour. Stalk 2 edged or leaflike, but thicker below the spadix, which issues from one of the edges, about a foot above the root, 2 or 3 inches long tapering, covered with numerous thickly set, pale green flowers, characterised as in the family. Native of Europe and of moist and cool parts of India, also of North America. St. and Ch. 32. Nees von E. 24. The rhizoma, or creeping procumbent stem, which throws up leaves from its upper and roots from its lower surface, is flattened, jointed, or marked with the semicircular impressions of the leaves, of a light brownish colour externally, with a reddish tinge in the inside. The odour is strong and aromatic, but not very agreeable, the taste warm, bitterish, aromatic, and a little acrid. It contains Volatile oil, Resin, Extractive, Salts, woody fibre, and water.

*Action Uses.* Aromatic Stimulant. It has been as frequently prescribed in conjunction with bitters, as the Chiretta and Bonduc Nut, and with success as an Antiperiodic in Agues. In powder in doses of gr. x.—sc. j ; or in infusion (oz. jfs. —oz. ij.—j.—Aq.) in doses of oz. 1½.—*Royle.*

(43) *ACOTYLEDONES*, or *Acotyledoneæ*, the name of the first class in Jussieu's 'Natural System of Botany.' It is derived from the circumstance of all the plants which it comprehends vegetating and without the aid of the seed-lobes called cotyledons. Such plants are also in all cases destitute of flowers, and are in fact the same as what Linnaeus called *Cryptogamia*. They are also called *Cellulares*. —*Eng. Cyc.*

(44) *ACROGENS* (from *akpos*, the top-most, and *γεννᾶω*, to produce); in Botany, one of the primary classes of the Vegetable Kingdom, according to the Natural System. This class, with identical limits, is also known by the following designations:—

(45) *ACOTYLEDONS* (Jussieu), so named from the fact of the absence of cotyledons amongst this class of plants—*Exembryonata* (Richard), designating the ab-

## ACROSTICHON.

sence of any regular embryo in the reproductive cells, or spores.

*Cellulare* (De Candolle), denoting the general absence of vascular tissue and the prevalence of cellular tissue in these plants.

*Agamæ*, of various authors, implying the absence of the necessity of the union of two cells in order to reproduce a new individual.

*Cryptogamia* (Linnaeus), intended to convey the idea that if two cells were necessary to the reproduction of the new plant in this class, it was not obvious, as in the *menogamous* plants.

The *Acrogens*, as equivalent to the above expressions for the same class, embrace all those plants which are included in the above definitions. This term itself is, however, only applicable literally to those plants which, destitute of flowers, possess a stem growing in a manner distinctive from those called *Exogens* and *Endogens*. It has been thus restricted by Lindley in his 'Vegetable Kingdom,' and he places the stemless flowerless plants in another class, called *Thallogens*. The structure of the stem, however, is at best an artificial character, and the adoption of the terms for the classes expressive of its characters, has rather been accidental than necessary. On this account it is perhaps better to regard the *Thallogens* as a section of *Acrogens* than an independent and equal group.

The stems of *Acrogens* differ much in appearance from those of *Exogens* and *Endogens*. The wood is not secreted from layers of tissue, which have the power of reproducing regular Zones of wood, as in *Exogens*, or a regular arrangement of vascular and cellular tissue, as in *Endogens*. There is generally but a single ring of vascular bundles even in the ferns. These vascular bundles do not go on increasing in size, but are all developed together. The lower part of the stem does not continue to increase in size, and its growth is determined by the development of new vascular bundles in connection with the leaves of the point or upper part of the stem hence their name. In the Liverworts and Mosses there is only a simple vascular bundle in the centre of the stem. In *Isoetes* too, there is a ring of vascular bundles. Science is very deficient in good observations on the structure of the stem of these plants.—*Eng. Cyc.*

(46) *ACROSTICHON*, (from *akpos*, a point, and *στίχος*, a row) a genus of Ferns, most of which require in Europe, stove heat in cultivation. The whole of the species now referred to this genus are extra-European, being inhabitants of the West and East Indies, and Australia. Dr. Hooker mentions that one of the genus clothes the Betel Palms on the Megna, with the most elegant drapery. It is the *Acrostichum scandens*, and is a climbing fern with pendulous fronds. At another place he found parasitic Orchids growing

on the trees, which were covered with this climbing fern (*Acrostichum scandens*), so that he easily doubled his flora of the river banks before arriving at Maldah. — *Barker, Him: Jour. Vol: II. p. 338 and 351.*

(47) ACTINIADÆ, a family of Helianthoid Polypes, having for its type the old genus *Actinia* the *Sea Anemonies*. It has the following characters: Animal single, fleshy, elongate or conical, capable of extending or contracting itself, fixed by its base, but with the power of locomotion; mouth in the middle of the upper disk, very dilatible, surrounded by one or more rows of tentacula; oviparous and viviparous; marine. — *Eng. Cyc.*

(48) ACTÆA ASPERA is sometimes collected in China as the scouring rush is for cleaning pewter vessels, for which its hispid leaves well fit it. — *William's Middle Kingdom, p. 286.*

(49) ADANSONIA DIGITATA, ETHIOPIAN SOUR GOURD. Lin.

*Papara poollie pullum, TAMIL. | Bonnie Umbie, DUK.*

Its bark and leaves have been recommended by Du Chaissing, as a febrifuge. — *Ainslie, Ind. Ann. page 372, No. 6.*

(50) ADEN. In giving a "Sketch of the Geology of Aden, on the Coast of Arabia," Mr. Frederick Burr, remarks "it is not I believe generally known to English geologists, that we have now within the limits of the British dominions perhaps the finest example in the world of extinct volcanic action—I allude to Aden, our new settlement on the coast of Arabia, where I had an opportunity of spending a short time in the early part of the present year. Imperfect as the following description, the result of hasty examination, may be, it will still embrace a few principal facts respecting this interesting locality, and serve at the same time to direct towards it the attention it so well deserves."

The promontory of Aden is situated about eighty miles eastward of the Straits of Bab-el-Mandeb, in latitude 13° north; and it consists of a bold cluster of volcanic rocks rising into lofty and jagged peaks, which are connected with the main land of Arabia by a low sandy isthmus. The extreme length of the promontory may be about six miles, the breadth half as much. The loftiest and most prominent portions of the whole mass are volcanic, and the lower portions are partly volcanic also, but exhibit many beds of consolidated sea-sand, which have been more or less elevated above the general level of the ocean. The most interesting portion of the promontory is however an immense volcanic crater, which is situated at the extremity next the main land, and in the very centre of which the town of Aden with the British cantonment stands. This magnificent crater is nearly circular in form; its diameter is probably about a

mile and a half, and it is surrounded on the northern, western, and southern sides with precipices chiefly composed of lava, and rising from 1000 to 1776 feet in height, the latter elevation being that of the "Gebel Shunsam," a lofty range of volcanic peaks, which form the crater's western side. On the eastern side the wall of the crater has subsided or been broken down for about half a mile, thus allowing the sea to come almost close to the town, and forming a small bay, generally occupied by native Arab vessels. Still however the lofty and abrupt island of "Seerah," about the middle of the gap, serves as it were to connect the broken portions, and almost to complete the original circle of the crater. Northward of this great focus of eruption, and ranging to the extremity of the promontory, is an immense mass of lofty and jagged rocks, all composed of lava. They have indeed much the appearance of a cluster of smaller volcanic craters, the sides of which have been washed away to the eastward by the action of the sea; but on this portion of the promontory, I was able to bestow but a slight and hurried examination.

The interior of the great crater in which the town of Aden stands, presents almost a flat surface, and is not elevated very much above the sea-level, the volcanic orifice appearing to have been filled up so far, partly by the crumbling in of the sides, and partly by the matter which may have washed in from the sea. The crater itself, though at first sight almost perfect, has manifestly undergone some rude shocks, the effect of which are very apparent on examination. It has in fact been cleft entirely through in one direction and partially so in another; a great fissure ranges across it from north to south, and the two rents formed by it in the walls are called the "nothern" and "southern passes," the former of which being very important in a military point of view, as it affords the principal ingress, is strongly fortified. The western half of the crater stands entire, forming the "Gebel Shunsam," which, as already noticed, is 1780 feet in height, and has within it a curious ledge of rocks about half its own elevation, which I had not time to examine. The eastern half of the crater has evidently undergone a partial subsidence; as it does not rise to more than half the height of the western side, and it appears to have separated in two parallel lines at right angles to the great north and south fissure. It is on the line of these subordinate fissures, that the sea, as before noticed, has broken in, and between them stands the island of "Seerah," which, although left as it were without support on both sides, has itself very slightly subsided.

While viewing the grand disruptions of this great volcanic mass, which although of com-

manding altitude and several miles in circumference, has evidently subsided, like a cottage undermined by a neighbouring stream or river. I naturally looked back to the great catastrophes which had happened on the spot, and endeavoured to determine their nature. The volcano itself may probably have been submarine in the first place, and successive eruptions may have gradually elevated it above the level of the sea. After this its paroxysms appear to have become less violent, as otherwise the sides of so vast an orifice might have attained a much greater elevation than 1700 or 1800 feet. From the great subsequent subsidence on the eastern side, it would appear that in that direction the volcano had been gradually undermined, till at length it cracked from north to south, and the subsidence of the eastern half took place. This enormous mass, however, in subsiding, seems to have cracked again into three portions by fissures at right angles to the direction of the principal movement. The subjoined woodcut will render this explanation more clear, and make it better understood.

Such appearing to be a brief outline of the physical history of this volcano, the eruptions of which were probably accompanied by the throwing up of smaller cones to the northward, I shall now briefly advert to the various rocks which compose the promontory of Aden, and the phenomena they present. The rocks which I observed were the following:—A dark brown or chocolate-coloured lava, generally of a very cellular texture, which is by far the most abundant rock. It forms all the high peaks of the upper part of "Seerah" Island, and the bold cluster of rocks at the northern extremity, called the "Ras Marbel," and it in many places constitutes the whole mass down to the sea level. This enormous accumulation of lava is sometimes, especially on the east side of the great crater of Aden, separated in the middle by a very thick bed of greenish porphyry, having generally a slightly lamellar structure. This porphyry is itself interstratified with red ochreous beds, which occur also between it and the lava, and appear to be derived from either decomposed lava, or from showers of volcanic matter, afterwards converted into an ochreous clay. Near the "northern pass" I observed a curious granular rock, probably a volcanic breccia; but having lost the specimens I collected, I am unable to describe it with any precision. Apparently at the base of all the above rocks, there are in places, especially near the "northern pass," thick beds of slightly consolidated sea-sand, which seem by their diagonal stratification to have been drifted by opposing currents, and may probably have formed the bed of the sea, when this great submarine volcano first broke forth. In the northern part of the promontory, the flat

line of coast, between the volcanic peaks on the one side and the sea on the other, is evidently merely a raised beach, where the loose sea-sand is consolidating into a tolerably compact sandstone, owing to the action of a tropical sun upon the calcareous matter of the sand. This formation of recent sandstone is further interesting from its inclosing numerous existing shells and corals of the adjoining Arabian sea. As regards the stratification of the rocks here described, the porphyries and volcanic products have generally an inclination of about 15° from the crater, but in some places their position is irregular and contorted.

Independently of the great fissures and lines of subsidence before noticed, the volcanic rocks of Aden present numerous and striking examples of dykes raking through them like walls, and generally almost perpendicular. These dykes appeared to me to be chiefly filled with siliceous matter, and to be both harder and more compact than the adjoining volcanic rocks. The most prominent and remarkable of them is one near the "main" or "northern pass"; it is several feet wide, and has almost the appearance of a vast wall crossing the mountain. Other conspicuous dykes are seen in "Seerah" Island, cutting through both the beds of porphyry and lava. I observed in many places small veins of chalcedony intersecting the lava.

Some pieces of black and green obsidian from the volcanic rocks of this promontory were kindly given to me by Dr. Maholmson; but I did not see the places where they were collected, nor learn the circumstances under which they were found. The green obsidian is quite glassy in its texture, and in some of the specimens the colour is very pale. One piece is very interesting, the obsidian itself running in small veins to a coarse cellular trachytic rock, and suggesting the idea of materials of very unequal fusibility, having been exposed together to the intense heat of the volcano, the result being a segregation of the most fusible portions, and the melting of them into obsidian, while the adjacent refractory matter has undergone but little change.

The above hasty sketch of this interesting tract is given as an imperfect outline only; but should this port be abandoned, even these rough notes may become valuable, as no European could then visit this spot. Should, on the other hand, the settlement be retained, the present notice may attract the attention of future travellers who may have more leisure to examine the promontory of Aden. I would remark, in conclusion, that few contributions to geology would be more valuable than an examination not only of Aden but of the other volcanic groups, some of them as yet hardly extinct, which extend north-westward from that promontory through at least the southern portion of the Red Sea.—*Mr. Burr.*

(51) ADENANTHERA PAVONINA. The rose-coloured fruit of the "Mangrove" yields a beautiful deep red-colour, approaching purple; the wood of the *Adenantha pavonina* dyes red, and the wood of the black varnish tree affords a red dye.—*Mason*.

(52) ADENNMA MYSSOPIFOLIUM. Chota Chirayta, *Kind.* is common in various parts of Southern India, is very bitter, also somewhat laxative, and much used by the natives as a stomachic.

(53) ADIANTUM CAPILLUS VENERIS, or Venus' hair, is indigenous in the Himalayas, where it is called *shuer-ul-jin*, or fairy's hair. The names *Moobarkha* and *hungraj* are also applied to it, and like the European article it is given as an expectorant. In Europe it is the basis of the celebrated *Syrop de Capillaire*.—*O' Shanghnessy*, p. 677.

An *Adiantum* or maiden hair, a small handsome fern, is seen in Tenasserim, in the crevices of old ruins and walls everywhere, of the same genus and nearly resembling the English maiden-hair "the prettiest of all ferns."—*Mason*.

(54) ADRUK, GINGER; ZINGIBER OFFICINALE.

(55) ÆGAGRUS, a wild species of Ibex, called Paseng by the Persians. [Goat.]—*Eng. Cyc.*

Beal, Bel. or Bela, HINDEE | Maredoo, TELINGA.

AND BENGALÉE.

Beli, CYNGALESE.

Tanghula, MALAY.

Willa maram, TAMOOL.

Bengal Quince.

A tolerably large and erect tree, 20 to 30 feet high; bark ash coloured; branches few and irregular. Thorns axillary, in pairs, single, or none, very sharp and strong; leaves ternate middle leaflet petiolate, lateral ones almost sessile; panicles small, terminal and axillary; flowers large and white; berry large, subspherical, smooth, with a very hard rind, from 10 to 15 celled; the cells contain, besides the seeds, a large quantity of an exceedingly tenacious transparent mucus which on drying becomes very hard, but continues transparent: when fresh it may be drawn out into threads one or two yards in length, (and so fine as to be scarcely perceptible to the naked eye) before it breaks. Seeds from six to ten in each cell, oblong, a little compressed, woolly, attached to the inner angle

of their cell. It is a native of most parts of the East Indies, and is common about pagodas, as the natives have a deep reverence for this tree. The fruit of the Indian Bael has lately been employed at Madras and is found useful in chronic dysentery and diarrhoea; the tree has been propagated from indigenous seeds at the Agricultural Garden and young plants are in considerable demand. The conserve prepared by Mr. Pound, of Oxford Street, from half ripe fruits exported from Calcutta, has been imported to Madras by Messrs. Flynn and Co. Eaten as marmalade, it is serviceable in relieving irritation of the mucous membrane and the pulp is much used by the natives for its astringent qualities. The late lamented Dr. Pereira, has given a short notice of this plant and its medicinal products, in the Pharmaceutical Journal vol. X. p. 165, and Dr. James Ranauld Martin writes "On what the curative property depends, I know not; it is certainly not astringent to the taste, or (at all events) very slightly so, I am inclined to believe that much of its efficiency may reside in the thick mucilage which surrounds the seeds of the fruit. A singular property of the fruit is this, that it does not merely restrain undue action of the bowels, as in diarrhoea and dysentery, but also in cases of obstinate habitual constipation acts as a mild and certain laxative. It may be said in all cases to regulate the bowels: *Lancet*, July 1853 p. 53. Dr. Horsfield states that, in Java, it is considered to be possessed of astringent properties (*Trans. Bot. Society*, vol. 8, p. 25) and the same property is mentioned by various other learned authors of the last two centuries as Burmann, Bontius, Garcias ab Horto and Caspar Bauhin. It is remarkable that the properties of a plant so easily procured, and so often sent to Europe, a plant figured by Plukenet, Rheede and Rumphius and subsequently represented in the standard works of Roxburgh and Wight should still be considered sub-judice. The properties of the Bael fruit in relation to the animal body appear to be nutritive, refrigerant and astringent—the two former properties are shared by almost all the fruits of the aurantiaceæ and the astringent principle may be a modification of Tannin, as stated by Pereira, or it may be owing to the large quantity of cohering mucus in the pulp of the fruit. I have found both the Conserve and the Liquor Belæ as prepared by Mr. Pound, of Oxford street, very useful in five or six cases of obstinate diarrhoea and in the person of a young officer from Burmah who suffered from great irritability of the mucous membrane after the expulsion of Taenia by Kousso. The conserve was spread upon bread like marmalade, and the Liquor Belæ was given in doses of two table spoonsful three times a day. My experience of the therapeutic effects of this remedy has been but limited, as much of the fruit is not at com-

## AGAMA.

mand in Madras, but I feel confident that I have observed the astringent and refrigerant effects of the pulp which in my opinion, possesses remedial properties of considerable value. The testimony of the eminent authorities quoted above, added to the experience of Mr. Sanderson and other Indian practitioners of the present day will, I trust, set at rest the question of the medical efficacy of the Bael fruit.—*Dr. Cleghorn, in Indi: Anna. Medi. Science, page 222, 1854.*

### (57) "AESCHYNOMENE ASPERA." Shola, HIND.

Shola is advantageously used for making models of Temples, Houses, &c. which possess all the appearance of ivory. Beautiful specimens of these are manufactured at Trichinopoly.—*M. E. Jur. Rep. of 1855.*

### (58) AESCHYNOMENE SESBAN.

Kedagu, RHEED | Sovinda, TEL.

This small beautiful tree is in general found in the vicinity of villages but is of few years duration; flowers chiefly during the wet and cold seasons.

There is a variety of this tree with yellow flowers which is not so elegant as the above described, and another with red flowers.

The wood is said to make the very best charcoal for gunpowder.—*Roxb. Rohde M.S.S.*

(59) AESCHYNOMENE PALUDOSA is the Sola, or light sponge wood of Bengal.—*O'Shaughnessy, page 295.*

Eagle Wood, ENG. | Kalambak, Gahrn, Kayu.  
Agarhu, SANS. | MALAY AND JAVANESE.

See EAGLE WOOD.—*C. of I.*

(61) AGAMA, in Zoology, a genus of reptiles belonging to the order *Saurians*, and family *Iguanians*, of Baron Cuvier. In the form of their heads and teeth the species of *Agama* resemble the common lizards, but differ in the imbricated scales which cover their tails. These animals have the body thick, and shorter in proportion than the generality of the saurian family; the skin is lax, and capable of being distended or puffed out with air at the will of the reptile; the whole body, as well as the head, neck, and feet, is covered with minute rhomboidal or hexagonal scales often prolonged in the form of little spines, and bristling when the body is inflated with air. The head is short, broad, and flat, particularly towards the occiput; the neck also is short, and the tail seldom longer than the body. These proportions give the Agamas much of the hideous and disgusting appearance of toads. Other species of this division having pores on the inner surface of the thighs, are the *Leiolepis* (*A. guttata* of M. Cuvier) of Cochinchina, with white rays and spots on a bright blue ground. And lastly the *Physignathes* (*A.*

## AGRICULTURE.

*coccineus*), from the Malayan Peninsula, remarkable for its large size, uniform blue colour but more particularly from being one of the very few species of saurian reptiles, which feed upon vegetable substances. Barot Cuvier assures us that it lives entirely upon fruits and nuts. The *A. calotes*, of a bright blue colour with transverse white marks on the sides, from the Molucca Islands. The *Lophyres* (*A. gigantea*, Kuhl), with a crest of long-elevated spines on the neck; and the *Lyriocephalus* (*A. acutata*) which has a similar elevated crest along the back, and the tail keel-shaped. This latter species, in many respects a most singular reptile, inhabits Bengal, and lives upon fruits.—*Eng. Cyc. p. 87.*

(62) AGARECUS ALBUS, AGARICUS MUSCARIUS,—now but little used in Europe, but the Eastern doctors continue to employ it as much as in former times. For instance, in indurations of the liver or spleen, ague, epilepsy, bilious and mucous disorders, stoppage of urine and menstrual discharge, pain from the stings of scorpions, etc. They conceive that it may be injurious to the stomach, and to the bowels, provoking colics and even apoplexy.—*Honigberger, p. 223.*

(63) AGATHOTES, (from *ἀγαθός*; goodness), a genus of plants belonging to the natural order *Gentianaceæ*. It is distinguished by having a rotate 4-parted corolla, with two pores at the base of each segment. *A. chirayta* is a well-known species, a native of Nepaul, Kumaon, and the Himalayas. The specific name is an imitation of the Sanscrit and Bengalee names. This plant has been known for a great length of time as a remedy in India, but has only recently been introduced into European practice. It is an annual plant, about three feet high, flowering in the rainy season. The whole plant is taken up, and the proper time for collecting it is just when the flowers begin to wither. When dried it has an intensely but agreeable bitter taste, and is destitute of aroma. The root is possessed of the greatest bitterness. The bitter principle is readily imparted to water and to alcohol.—*Eng. Cyc. p. 92.*

### (64) AGRICULTURE AND GARDENING.

Khet Karn, HINDOOE. | Zarayat, PERS.  
Khetec Barea, HIND. | Pairoodagaradoo, TAM.

As the ground was, by Divine appointment, to furnish subsistence for man, and after his fall he was doomed to procure it by labour, husbandry, or the practical part of agriculture, was of necessity the first and most important occupation of the descendants of Adam; wherefore we learn from Scripture, that his two sons, Abel and Cain, were both employed in this manner, the former being a keeper of sheep, and the latter a tiller of the ground. With what implements this work of tillage was carried on, and what de-

gree of art was employed in producing the fruits of the earth, is left to conjecture; but writers on those early periods are generally agreed that the antediluvians were in possession of many arts and inventions which were in process of time lost, or at least but imperfectly retained among the different nations that were scattered abroad after the confusion of tongues. Agriculture was one of the arts which Noah and his posterity retained; for we find that he cultivated the vine. Those of the line of Shem appear to have followed the breeding and feeding of cattle: but those of the line of Ham, who took possession of Egypt, applied themselves to the tilling of the ground, and with so much ingenuity, industry and success, that, owing to the inundations of the Nile, and the consequent fertility of the soil, Egypt was enabled in the time of Abraham, and still more so in the time of Joseph, to supply its neighbours with corn during a period of famine. Nor were the inhabitants backward in assisting the liberality of nature: they busied themselves in embanking, irrigation, and draining, in order to derive all the benefits which the benignant river was capable of affording them. These works are said to have been carried on with particular spirit under the auspices of Sesostrius, 1800 years before the Christian era. So sensible were the Egyptians of the blessings which agriculture afforded, that in the blindness of their zeal, they ascribed the invention of the art to their god Osiris, and the culture of barley and wheat to their goddess Isis.

The Pelasgi, or aboriginal inhabitants of Greece, were among the number of those who lost all the primeval arts, and fed upon acorns and wild fruits, until they were led by the Egyptians, with whom they had an early communication, to the cultivation of the ground. Like them, too, they placed their benefactress Ceres, to whom they ascribed the introduction of corn, among the number of their deities; a goddess whom authors agree was no other than the Egyptian Isis. In the time of Homer, agriculture was in such esteem that King Laertes laid aside his royal dignity, that he might cultivate a few fields. Hesiod, the contemporary of this author, has devoted a whole poem to the labours of the field in the different seasons of the year. Of other writings among the Greeks, on agriculture, little remains, except a treatise by Xenophon on rural affairs, and scattered notices on the subject in the works of Aristotle and Theophrastus; but we learn from Varro, that there were in his time not less than fifty Greek authors to be consulted on agricultural matter.

The Jews, as Scripture informs us, applied themselves, when they came into the land of Canaan, to the cultivation of the soil, having each their territory allotted to them. We may

also infer, from the frequent allusions to this subject to different parts of the Old Testament, that husbandry formed their principal occupation. The laws of Moses have, many of them, for their object the regulation of their flocks, their herds, and their fields. David cultivated his own land, having officers to take charge of his flocks, his herds, his camels, his asses, and his warehouses of wine and oil, &c. Elisha was in the field with twelve yoke of oxen when Elijah found him. Besides the frequent mention of husbandry business in different parts of the sacred writings, as the digging of wells, the planting of vineyards, the leasing, gathering in, threshing, sifting, and winnowing of corn, with a number of other things of the like kind.

That the Carthaginians did not neglect agriculture is evident from this, that they had writers on the subject; of whom a famous general, Mago, was one, who is quoted by Varro. He wrote no less than twenty eight books. It is probable that, under the auspices of these people, agriculture flourished in Sicily, which was afterwards the granary of Rome.

No subject engaged the attention of the Romans more than agriculture, theoretically as well as practically. They divided their time between war and husbandry; their greatest men, in the early ages of the republic, being employed alternately in the one and the other. Cincinnatus was taken from the plough to fill the office of dictator; and Regulus besought the senate that he might return to his little farm for a short time, to prevent it from being ruined. Pliny observes, that the Romans ploughed their fields with the same diligence that they pitched their tents, and sowed their corn with as much care as they raised their armies. When riches had introduced luxury and artificial manners and habits, the labours of the field were performed by their slaves; but there remained many among them of the higher orders who directed their personal attention to the subject. The writings of Cato the Censor, Varro, Pliny, Columella, and Palladius, as well as those of the poet Virgil, abound with practical and useful observations on the whole ground of farming business. At the same time they all agree in lamenting that agriculture was not pursued with the same zeal as formerly. The great among the Romans had town houses as well as villas, and living more in the former than in the latter, the management of their farms was left to their bailiffs or servants. The ox, which was the principal beast of burden among the Egyptians, the Jews, the Grecians, was also highly esteemed among the Romans. Many directions for the breeding, breaking, feeding, and working this animal are to be found in the writers abovementioned, as also in regard to the management of bees, which were highly prized. As to the implements of husband-

ry used among the Romans, the description of them not being illustrated by any representation, it is not easy to speak precisely of them; but it is clear that they used the plough with and without wheels, with and without boards, with and without coulter, also with shares of different constructions. A reaping machine is likewise spoken of both by Pliny and Palladius, which was driven by an ox; but for the most part they cut their corn with the hand, either with the hook close to the ground, or only the ears with a curved stick and a saw attached to it, or otherwise they cut the stalks in the middle, leaving the stubble to be afterwards mowed. They threshed either with a machine composed of rollers, or with rods or flails, or they trod it out with their feet. Hay making was performed among the Romans much in the same manner as at present. Harrowing the corn was particularly recommended by the Roman writers; who also speak of hoeing, weeding, watering, draining, and fallowing the ground, which was universal among them.

Agriculture shared the fate of all the other arts on the decline of the empire: from the time of Pliny to the fifteenth century, there is no work extant on the subject, except the *Geoponics*, which was published by Constantine Pogonatus, and probably collected by the emperor himself. Crescenzo, a writer of Bologna, was the first who called the attention of his countrymen to this subject after this long interval. His little work, which was collected from the Roman writers, was followed by some other Italian productions, but probably nothing contributed more to give an importance to agricultural pursuits, than the introduction of the feudal system, which gave to every man a rank and distinction according to the quantity of land he either possessed or occupied; for not only the great lord, who was the owner of the soil, or reaped the fruits of it, but also his tenants, who cultivated it, were invested with political privileges that were enjoyed by no other members of the community; and altho' the feudal burdens and restraints have ceased, yet the privileges and advantages attached to the possession of landed property still give it a paramount advantage. Hence it is, that since the revival of the arts, the science of agriculture has been zealously cultivated by the higher orders. The writers likewise on this subject have within the last century been more numerous than at any former period; and every effort has been made by experiments, inventions, and improvements, to render the land productive. Nor have these efforts been without effect, for, notwithstanding the immense increase in the population, there has been no such scarcity as we read of in former times.

*Hints on the theory and practice of gardening.*

—A plant is a living being, like an animal requiring, for its continual existence, a constant supply of suitable nourishment, which it obtains by absorption from the soil in which it grows. This is effected through the pores or spongioles of the newly formed fibrous roots, which often extend to a great distance round the base of the stem, occupying a greater circle even than the branches. These pores are only permeable by fluid or gaseous matter, and nourishment must be presented in one of these forms before it can be admitted: to obtain therefore a small quantity of nourishment, a very large quantity of water must be absorbed.

Under the stimulus communicated by exposure to light and heat, the superfluous water thus introduced, is partly thrown off again, in form of perspiration, partly decomposed and converted to nourishment by the leaves, which, at the same time, by their vital powers, aided by the action of light, separate and assimilate the nutritious matters held in solution by the water, forming from them, the proper sap, whence all the various products of vegetation is derived.

While the functions of nutrition and exhalation balance each other, the health of the plant is preserved; if they become deranged, so that either is in excess, disease or modification of form results. On these few and simple facts nearly the whole of the complex system of Horticulture may be said to rest. If it is our object to obtain succulent vegetables, we excite great luxuriance of vegetation by planting in a light rich soil easily permeable by the most delicate fibres of the root, which, only, are furnished with absorbing pores, and give abundance of water or liquid manure, not confined to the foot of the stem only, but spread over a considerable surface, so as to make sure of supplying even the most remote spongioles with fluid. By this arrangement and free exposure to light, the leaves and stalks are greatly developed, and enabled to assimilate or throw off in form of perspiration the whole of the excess of moisture thus absorbed. But in a like proportion, the production of flowers and fruit if prevented, those buds, which otherwise would have been developed as flowers, are liable to push into leaves and branches. An opposite plan of treatment;—planting in a light poorish soil and giving little water, by diminishing luxuriance, has a tendency to produce an accumulation of nutritious sap, a deposition of wood, and in due season the free development of flower buds and fruits. Plants cultivated for their succulent leaves, such as all oleraceous vegetables, therefore, require the one method of treatment, those intended to supply flowers or fruit the other.

The equilibrium between absorption and exhalation may be temporarily greatly disturbed, without injury to the health of the plant, by changes

## AGRICULTURE.

in the state of the air : a dry warm atmosphere or windy weather producing copious perspiration, a humid and still one diminishing it. A knowledge of this fact is of great importance in transplanting, the success or failure of which often depends on attention to it.

**HEAT.** The effect of high temperature, the greatest enemy the horticulturist has to encounter in this country, requires to be more fully considered.

The extremes of temperature which plants are capable of bearing without destruction of vitality, has not been accurately ascertained, but it is known, that some seeds may be boiled and still vegetate, and some plants are found to endure the most intense cold known on the earth. Sir John Herschel observed the temperature of the soil of his bulb garden at the Cape,  $159^{\circ}$  Fahr. between 1 and 2 P. M. and found a seedling fir, of the years planting, quite healthy, while a thermometer buried four inches deep in contact with it, marked one day, (3d December) successively, between the hours of  $11\frac{1}{2}$  A. M. and 3 P. M. —  $148.2^{\circ}$  —  $149.5^{\circ}$  —  $149.8^{\circ}$  —  $150.8^{\circ}$  and  $148^{\circ}$ .

In India, so far as we have been able to ascertain, no similar set of observations has been made, but there is reason to infer, from known data, that when the subject is more attended to in India, the heat of the soil during our hot weather, will be found much higher than either of these observations indicate. We know, for example, that we never can get cabbages, cauliflowers, knoll-kolls, &c. to flower in the Carnatic, while at the Cape the saving of seed of these plants, as an article of trade, is constantly practised. Dr. Coulter mentions, that in South America, he had observed the temperature as high as  $140^{\circ}$ , but the circumstances in which the thermometer was placed is not mentioned, which leaves room to suspect the experiment was imperfectly conducted, as Mr. Foggo, of Edinburgh, succeeded in obtaining in July, at that place, with a large thermometer, having the ball covered with black wood, an indication of  $150^{\circ}$ . In India, it is probable a thermometer so prepared, or the ball simply blackened by being smeared over with mixture of gum, and lamp black, and suspended fully exposed to the sun's rays, would, at some seasons, indicate as a common occurrence a temperature perhaps a little short of  $200^{\circ}$ . In December it rises to  $130^{\circ}$ .

In repeating such observations it is desirable that treble sets of experiments should be made: one with the instrument freely suspended, to mark the temperature of the air, another having it simply in contact with the ground, to show to what extent the surface accumulates heat from absorption of the sun's rays, and the third set at 1 and 2 feet deep, to ascertain the mean temperature at the depth to which roots usually ex-

## AGRICULTURE.

tend. In the second set the thermometer should not be placed in herbage, as Mr. Foggo found another thermometer similarly prepared but resting on herbage indicate only  $119^{\circ}$ .

There are no want of registers of the thermometer in India but not a single observation, neither on the temperature of the soil, nor on the intensity of the sun's rays as received on the blackened ball of the thermometer, do we find any where recorded, though of such vast importance to the Horticulturist.

The first effect of heat on a plant, which has for some time had vegetation checked by exposure to cold, is to expand the air contained in its cells: its fluids become thinner, the excitability of its tissue is aroused, and perspiration commences, the effect of which is to bring into play the absorbing power of the root and thus set the whole machinery of vegetation in action. The degree of heat which different plants can sustain is very different: those of tropical countries require a temperature that would kill those of Europe, and when removed there soon perish from cold, even in the warmest weather, if exposed to the open air. When the temperature is permanently too high for a plant, it is over excited: if the atmosphere is at the same time moist its tissues grow faster than the vital forces of the plant are capable of solidifying them, its excitability is expended, the vital functions are deranged and a state of debility is brought on. Such plants are soft and watery, with thin leaves and with no disposition to produce flowers; a slight lowering of temperature, in this enfeebled state affects them more than in other circumstances, and the abstraction of light rapidly destroys them. But if the atmosphere is dry and the loss of fluid by perspiration is greater than can be made good by the roots, the secretions are elaborated faster than the parts to receive them can be formed, the old leaves dry and the young ones perish as fast as they are formed. From these statements, it appears, that high temperature with moisture, leads to the production of leaves and branches only, while with dryness, within certain limits, it is favourable to the formation of all kinds of secretion.

The effect of cold is to increase their excitability, that is, it renders them more susceptible of being acted on by the stimulus of heat. Heat by its stimulus diminishes excitability, and if long continued would exhaust it altogether. Nature provides against this result by the periodical fluctuations of light and heat of the day and night. During the day every part of the plant is strongly excited, and its powers of evaporation and assimilation most energetic. As evening advances and the stimulus of light and heat is withdrawn, the excitement subsides and reaches its minimum during the night. Plants therefore,

like animals, have their diurnal seasons of action and repose. During the day their system is exhausted of fluid by exhalation of aqueous fluid, and during the night, when perspiration ceases, the waste is made good through absorption by the roots.

The alternation of seasons seems intended to produce the like effects in a more extended manner. This is very evident in the temperate zones, where the cold of winter arrests vegetation for months together, and renders the plant so excitable that the rise of a few degrees of temperature in spring at once excites active vegetation. To this state of increased excitability is owing the injurious effects which often result from exposing young and tender plants to the rays of the morning sun. It is much less so between the tropics, but here also it is observable, as indicated by the fall of the leaf of some trees and the nearly total arrest of vegetation in most, during some part of the hot season.

This wonderful similarity of effects in living beings, originating in the action of opposite extremes of the same cause (heat) has not received the attention which it seems to merit from philosophers, and no satisfactory explanation has yet been given of it. Before indeed any explanation can be given, it is indispensably necessary that our observations, on the proportion usually borne to each other, by the temperatures of the earth and atmosphere, should be more perfect, for, considering the great importance of heat in the economy of plants this knowledge is, for the purposes of gardening, of the greatest consequence.

From observations made in Europe, it has been attempted to deduce the relative temperatures of the air and earth within the tropics. Thus it is ascertained, that in England the mean temperature of the earth is between two and three degrees higher than that of the air, the same ratio will probably be found to hold good in India. This inference is confirmed by one set of observations in New Grenada, the mean temperature of the air of which for the warmest month is about  $84\frac{1}{2}$  while that of the earth at one foot below the  $85^{\circ}$  during summer. According to this ratio, the temperature of the earth at Madras, during the months of November, December, January, February and March, should be between  $79\frac{1}{2}$  and  $81^{\circ}$ ; that of the valley of the Thames in July, one foot below the surface, has been found to be only  $64.81^{\circ}$ . So great an excess of bottom heat must exert a very injurious influence on plants fitted for the lower temperature, by over stimulating and exhausting their excitability, enfeebling their powers and thereby incapacitating them adequately to perform the functions of assimilation by which their food is converted into suitable nourishment. It is impossible in any way, so far to obviate these inju-

rious effects of excessive heat as to enable us to cultivate plants of colder climates in warm countries?

This is an interesting question to the tropical horticulturist, but cannot, we believe, in the present state of our knowledge receive a satisfactory answer. If with the view of affording plants of colder countries a lower temperature, we cultivate them under shade, we deprive them of light, the agent by the aid of which the vital forces of vegetation are enabled to decompose the water and carbonic acid, by which they are nourished, and carbon in a solid state formed. The quantity of carbonic acid decomposed being in proportion to the quantity of light which strikes the leaf, and the healthiness in proportion to the quantity decomposed, the healthiness should be in proportion to the quantity of light it received by day. This fact goes far to prove that we err when we endeavour to obtain a cooler climate by shading the whole plant, thereby depriving it of the light by the action of which it is enabled to assimilate its juices, in place of the soil only, a view which seems further confirmed by the result of Mr. Poggio's experiment of placing the thermometer on a grass plot, the evaporation from which reduced the temperature 30 degrees. For this reason it seems probable that we shall succeed better in raising early crops, by shading the soil and keeping it cool, while by liberal watering, we furnish a constant supply of moisture both for evaporation from the soil and for free perspiration by which the plant keeps down its own temperature.

The correctness of this inference was in some measure proved one season in the Madras Horticultural Society's Garden, the finest beet root of the season being raised in beds covered some inches thick with sand, which seemed to have the effect of preventing hardening from too copious evaporation, and preserving the soil below always cool and moist, though comparatively sparingly watered. On this principle it seems not improbable, the true cause of the vigour and luxuriance of melon plants in the hottest seasons, may be partly attributed to their abundant foliage, which, forming a dense shade, preserves the soil cool, whilst the copious evaporation from their large leaves, by keeping them cool, counteracts the heat of the solar rays to which they are exposed. One hot season some beds were planted with the sweet potatoe, the procumbent stems of which rapidly covered the soil as with a carpet: from that time they continued to grow luxuriantly through the whole season, without requiring a drop of water, apparently from the same cause, as the soil under them was kept moist, and found several degrees cooler than that shaded by trees.

The effect of high temperature on a plant is to stimulate and exhaust its excitability, and

enfeeble its powers of assimilation: the primary object in Indian horticulture is to prevent these effects by artificial means. At the present season (December 1846) observations made during fine clear weather with bright sunshine show that the thermometer, suspended in the open air, and freely exposed to the sun, indicates at sunrise a temperature of about 70, and at 2 P. M. from 120 to 130—at that high degree it is very unsteady) or a range of from 40 to 50 degrees in eight hours. The heat of the surface of the earth it is probable exceeds even the higher indication. The temperature of the air fluctuates rapidly, and it is probable that in immediate contact with a healthy plant the temperature never exceeds 90°. Not so the soil. It absorbs heat and parts with it very slowly, thereby maintaining a constant high temperature about the roots, keeping up night and day the stimulus and excitement by which the plant is enfeebled. The object of our recommendation is to prevent this accumulation of heat about the roots, and allow plants to enjoy a more perfect period of rest during the night.

*Moisture of the soil and watering.*—Water is one of the most important elements of the food of plants, partly from their having the power of decomposing it and appropriating its elements to their support, and partly as being the vehicle by which the soluble matters found in the earth are conveyed into the general system of the vegetables.

Plants will not live in soils nearly dry, and excess of water is in many cases injurious to them: it is therefore a nice point in horticulture to ascertain the amount most congenial to the species under cultivation. To determine this point, in tropical horticulture, is one of the greatest importance, and one which must engage much of the attention of every one who would attain perfection in the art. The native practice in the cultivation of nearly all garden produce is to water very liberally, by deluging the ground at least once every day with water. The propriety of this practice we have often heard questioned, but, notwithstanding, it is generally adopted. We should feel happy indeed could we lay down precise rules to guide our readers in this matter, and still happier could we feel justified in stating that, in the native practice, it is used greatly in excess, as irrigation is unquestionably by far the most troublesome and expensive division of Indian Horticulture. That it is often used in excess we are almost certain, that it is often employed injudiciously is about equally certain, but that copious supplies are absolutely necessary in the culture of extra tropical plants is quite indubitable, and must be given to ensure success. We have already shown that the effect of high temperature is to produce very copious perspiration from the surface of the

leaves, that during dry warm weather, the fluids are daily exhausted by exhalation, and replenished again by absorption during the night. To provide for this daily waste a moist soil is indispensable, and the lighter and more porous the soil the easier it is kept moist. This is easily explained: soils containing quantities of clay, after a few waterings become puddled on the surface, and quite impervious to water, so that the descent of it to the roots is prevented, and the plants suffer from want of water even when liberally watered every day. Sand is, perhaps, generally speaking, the best remedy for such soils, and is most easily applied by being spread over the roots, as it there performs the double function of keeping the soil below cool, and acting as an excellent conductor of the water. If we do not make sure, by occasional examination of the soil, that the water really does get to the roots by free percolation, we labour in vain in covering our beds daily with water, and if it does pass freely and the soil is shaded, daily watering is not required, except for very young plants, as at that age the perspiration is much more rapid than in older ones, and the absorbing surface of the roots smaller.

Carrots, turnips, beetroots, knoll-coles and cabbages should have a light soil, through which both the delicate roots and water, can pass freely. They should be sown and planted in rows. Turnips and carrots often succeed well, sown broad cast apparently because the leaves by shading the ground about them keep the beds cool. But they then labour under the disadvantage of being too thickly set, the soil between which is kept loose and permeable to water, and at the same time cool, by being covered with sand or some kind of litter. Thus managed it will never puddle and less than half the quantity of water will suffice, as much evaporation from the soil and the great accumulation of heat, which renders copious watering so indispensably necessary, will thereby be prevented. In Spain and Italy, it is much the practice thus to protect the soil from the heat of the sun.

Mildew, which is often produced by dry air acting on delicate vegetable tissue, is prevented in annuals by abundant watering. Mr. Knight applied this fact to the securing late autumnal crops of peas. Evaporation both from the soil and leaves is much augmented in windy weather, wind having the effect of increasing the dryness of the air. During the prevalence of such weather, therefore, the supplies of water ought to be more liberal, and gardens ought, if possible, to be invariably sheltered by high hedges, as well as traversed with lower ones, or with trees trained on ornamental trellises, as without such protection it is almost impossible to make annuals and young trees thrive in such weather. And in such seasons peas are peculiar

ly liable to mildew, so much so, that in some inland stations, where the air is very dry, it is almost impossible to procure a dish of peas, even during the cool season, in clear dry weather. Liberal watering, covering the soils between the rows, and sowing in well-sheltered situations would probably obviate this tendency to that disease. While copious moisture is thus indispensable to plants in this hot climate, stagnation of water about the roots is generally injurious, and requires to be prevented by deep digging, and when that is procurable a light absorbent subsoil.

While treating of moisture it may be well to observe that in seed sowing, the soil should be merely moist, just so much water as the particles of earth can retain around and among them by the mere force of attraction. In India, therefore pots or boxes in which seed are sown, should be filled with light soil easily percolated by water, placed in well-sheltered situations and covered to prevent, as much as possible, the rapid evaporation caused by our warm and dry climate. Irregular variations of heat, light and moisture, by which the process of germination is sometimes accelerated, sometimes retarded, should be particularly guarded against, as such irregularities are apt to destroy the young plant. In sowing seed of the plants of cold climates, in India, the temperature is generally higher than what is considered most advantageous in Europe, and probably leads to the loss of many, which either do not germinate or the young plants soon after die. An instance of this kind was lately communicated to us. Two parcels of Mignonette seed, one direct from Europe, the other saved in Bangalore, were sown at the same time. They both vegetated equally favourably, but the former all died off a few days after they appeared above ground, the latter still survive and are vigorous healthy plants. We have heard it asserted that the idea of acclimating either plants or animals is visionary, this case seems to lead to an opposite conclusion. Lettuce, turnip and carrot seed saved in Madras, were sown on the Neilgherries and were found to answer much better and produce much finer plants than those raised from English seeds, other portions of the same seed sown in Madras do well though they come far short of the Neilgherry result. Turnip and carrot seed saved at Hydrabad are found to answer better in Madras than those from Europe or the Cape. These few facts go far to prove that if Horticulture was more systematically pursued in this country much might be done towards acclimating northern plants.

*Propagation of Plants*—On this useful branch of horticulture much has been written, and many methods are in daily practice besides the one just mentioned by seed,—such as by

budding, grafting, eyes, cuttings, layers, &c nearly all these are pretty well understood in this country, and more or less practised, though probably not so much as they might be. The extreme heat and dryness of the climate during a great part of the year are however greatly against most of them as practised in Europe.

On each of these various methods it is not our intention on the present occasion to dwell, though some of them merit attention, but shall confine our observations to cuttings, which being easily practised is much employed among us, though with less success in many cases than we should experience if well conducted. Of this operation it is remarked, the constitutional differences among plants is so great that some species will strike without any difficulty under almost any circumstances, while there are others which no art has yet succeeded in converting into plants. And it is by no means uncommon to find that, out of a potful of cuttings of the same species apparently all alike, and treated in exactly the same way, one will grow and all the rest fail. From this it is inferred that the principles of striking cuttings are still imperfectly understood, and that this is one of the points of horticulture in which there is the greatest room for improvement.

The point requiring most attention in this operation is, to take the cutting from well ripened wood, if possible during the season of rest, after the formation of its annual ring of wood and ripening its annual crop of seed or fruit. Such cuttings cut square off, set in small pots with the end resting against the bottom, in light soil, consisting of a large proportion of sand mixed with vegetable earth slightly moist, and kept in a cool rather dark place under a glass frame, to maintain an equally humid atmosphere until they begin to shoot, are placed in the most favourable circumstances for propagation. Provided the cutting continues to live, it is an advantage its not immediately beginning to shoot, and only one bud should be allowed to grow. It is of importance that the end of the cutting should be cut parallel to, and touch the bottom of the pot; the lemon and orange and many other plants, which without this precaution do not strike willingly, will readily do so when this is attended to. The object of it is to prevent the cutting absorbing water too rapidly, before it is possessed of the necessary apparatus of leaves, to throw it off by perspiration. An ingenious plan was invented by Mr. Forsyth, to answer this purpose rather more perfectly. "He puts a small pot into one of larger size, having first closed the bottom of the former with clay; then having filled the bottom of the outer pot with corks, he fills up the sides with propagating soil in which

## AGRICULTURE.

the cuttings are so placed that their root ends (cut to the proper angle) rest against the sides of the inner pot, the latter is then filled with water which passes very slowly through the sides until it reaches the cuttings." (*Gardener's Magazine*) "In many cases, especially in striking such plants as heaths, gardeners employ a stratum of silver sand, placed immediately over the earth in which such plants love to grow; the cuttings are inserted into the sand, but so near the earth, that the roots, presently after the emission, find themselves in it and in contact with a source of food. This sand answers the same purpose as placing the root end of the cutting in contact with the pot, and is an ingenious device for doing that with small cuttings which cannot be conveniently done otherwise, except with large ones." (*Lindley*.) The additional precautions are to cut the root end close below a leaf bud, to facilitate the emission of roots by the buds, and cover the whole by a bell glass with the edge pressed into the earth, for the purpose of preserving a uniform degree of humidity in the atmosphere breathed by the cuttings.

*Potting.*—This is an important part of practical horticulture, but so little thought of by writers of works on practical gardening, that we have never seen printed rules for its management until we met with them in Dr. Lindley's late work entitled "The Theory of Horticulture" (a work which should be in the hands of at least every amateur); on this account we shall on this head quote largely from that work.

Without entering on an examination of the advantages derived from potting, it may be observed generally that the operation places plants in a very artificial and upon the whole unfavourable condition for attaining the highest perfection.

This is so obvious, even in the case of small plants, that but for its convenience in enabling us to shift plants from place to place, for ornaments or convenience, or transfer those raised from cuttings or seed to the open soil without injuring their roots, it would be much less practised. It also enables us to cramp the roots and diminish the tendency to form leaves, and thereby increase the disposition to form flowers, and finally, in the management, during their earlier stages, of delicate plants, it secures constant drainage from the roots.

To set against these benefits, one of the most obvious inconveniences is exhaustion of the soil by the plant. The organizable matter, in a soluble state, contained in a garden pot must necessarily be small, is soon consumed, and an unhealthy state induced. To remedy this, liquid manure and frequent shifting is had recourse to: it is to the latter, however, that we must principally look for renovating the soil, and restoring

## GRICULTURE.

its permeability when consolidated by repeated applications of liquid manure, and thereby allowing more liberty of distribution to the roots. "It is not however, by mere exhaustion that potted plants render the soil unfit for their support. Every one knows that the soil of a farm will not bear year after year the same crop, but that one kind of produce is cultivated on a piece of ground one year, and is succeeded by some other, which practice constitutes the system of rotation of crops. It is notorious that a new apple orchard will not immediately succeed on the site of an old one, and that no amount of manuring will enable it to succeed. A wall border, in which fruit trees have been long grown, becomes at last insensible to manure, and requires to be renewed, and Dahlias do not 'like' the soil in which Dahlias were grown the previous year."

These phenomena cannot be explained on the principle of exhaustion of the soil, as that is made good by manure: it has therefore of late years been supposed that the *excretions from the roots* would account for the deterioration, and explain why plants cannot grow year after year in the same soil, this matter being assumed to be unsuitable to themselves, although harmless to different species.

On this theory considerable difference of opinion exists, but be the explanation what it may, the fact is certain, that to maintain plants in a healthy condition the soil must be changed, and explains why potted plants often shifted are more healthy than those treated otherwise. "It is not however merely for the purposes of removing deteriorated earth, or adding manure that shifting is important, all potted plants have in course of time their ball of earth, by the continual passage of water through it, reduced to a state of hardness and solidity unfavorable to the retention of moisture or the growth of roots, and this of course is cured by the operation of shifting if judiciously performed."

Another disadvantage which plants in pots suffer, is the exposure of their roots to great variations of temperature, owing to their invariably taking a direction towards the side of the pot; which, having reached, they do not turn back, but spread over its surface, till at last they form an entangled stratum enclosing a ball of earth. There they are in contact with a body subject to great variations of temperature and moisture according as it happens to be exposed to the sun, or to moist, or dry air in motion. The heat of the sun will, in such circumstances, be burning the roots on one side of a pot, while the cold produced by evaporation from its surface is almost freezing them on the other. To obviate this very serious drawback in potting plants, it has been proposed to use double pots of different

sizes, filling up the space between with moss or other substance retentive of moisture.

In pot planting it is essential to success that the drainage should be most carefully secured, by placing quantities of broken tiles or rough gravel in the bottom. As the tendency of the roots is always towards the sides of the pot, where they remain exhausting the small quantity of earth with which they are then in contact, and profiting nothing by the main body of soil, there is much nicety in the management required to prevent that, the principle of which is never to put a small young plant into a large pot at once; but gradually and successively transfer it to large pots as it advances in size. I shall conclude this, to florists, interesting division of these notes, by a rather long extract from Dr. Lindley's *Theory of Horticulture*.

"As the proper manner of managing potted plants is of the first consequence, I transcribe the following mode of treating the Balsam from a very sensible paper by the Rev. William Williamson.

"As soon as they have got four leaves, I transplant them singly in the smallest pots I can procure, and in such a manner that the stem of the plant may be covered somewhat more than it was at first, and then all are to be again placed in the frame. In a short time, if there be a sufficiency of heat, that part of the stem which is covered with the mould puts forth fibres by which nourishment is conveyed more immediately to the principal stem of the plant. As soon as the plants are a little advanced in growth, they are again removed (if possible without disturbing the earth) into somewhat larger pots, still planting them rather deeper than before. The same process is repeated five or six times, till, at last, they are removed into their final pots. I have found it best to give them their last removal after they have opened their first blossoms, as it gives additional brilliancy and size to the flowers. By following this method the plant acquires extraordinary vigour, throwing out its branches from the surface of the mould, exhibiting flowers nearly as large as a full blown rose, and a stem measuring two, and sometimes three, inches in circumference!" (*Hort. Trans.* III 128)

"The plan of continually sinking the stem with every succeeding potting, is useful to the Balsam, because it puts forth roots in abundance from its stem; and to all plants having the same property, the same practice is desirable: but not to others, which, if their stems do not root as fast as they are buried, will suffer injury by the sinking."

"It is by paying constant attention to the shifting of the growing plant, by the employment of a very rich stimulating soil, and by a thorough knowledge of the kind of atmosphere which suits them best, that have been obtained

those magnificent pelargoniums, cockscombs, balsams, and similar flowers, which have so often and so justly excited the admiration of even the most experienced gardener."

*Transplanting*.—The art of transplanting is among the most important business of the gardener, but the principles on which its success or failure depends, seem but imperfectly understood. Hence the discordance of opinion existing among writers on the subject. The following aphorisms from Lindley's first principles Nos. 40, 41 and 42, will explain in very few words what these principles are.

"40. Plants have the power of replacing spongioles by the formation of new ones so that an individual is not destroyed by their loss.

"41. But this power depends on the co-operation of the atmosphere and upon the vital powers of the species.

"42. If the atmosphere is so humid as to hinder evaporation, spongioles will have time to form anew, but if the atmosphere is dry, the loss by evaporation will be so much greater than can be supplied by the injured roots that, the whole system will be emptied of fluid before the new spongioles can form."

In these three propositions we have the key to this useful branch of the art. When a plant is taken out of the ground many of its roots are necessarily injured, and the remainder are less able to support the stem than before. This diminution of power will be in proportion to the degree of mutilation of the roots.

We have remarked above that plants have seasons of repose or inaction, and seasons of growth and activity. During the former of these, which usually happens in this country after the maturation of the annual crop of fruit, the demand on the roots is small, the fluids being stagnant, compared to what it is during the season of action when new leaves and shoots are forming, the flow of sap rapid and perspiration copious. The season for transplanting therefore is during the period of rest, as time is thereby allowed to form new roots and spongioles before that growth returns. For these reasons the best season for transplanting in Europe is immediately after the fall of the leaf, or in ever-greens, during wet weather, late in autumn or the beginning of winter. In this country these changes are not so well marked, as most of our trees are ever-greens and vegetation is always in progress, but by attending to the criterion furnished by the ripening of fruit we shall not greatly err. In Europe, damp or rainy weather is always considered advantageous, as the perspiration from the bark of deciduous trees and from the leaves of ever-greens is then least.

In the southern part of India we are seldom favored with such weather during the season of rest and cannot wait for it, as a fall of

rain is almost immediately followed by a renewal of growth. The most favorable time, therefore, for transplanting, is in still cloudy weather, and the plants transplanted should be immediately sheltered from wind, by being hedged in with bushes and shaded, to break the force of the wind and cut off the stimulating influence of the sun's rays. Still further to enable the mutilated roots to furnish the fluids required to counteract the effects of too free perspiration, the ground should be previously thoroughly soaked with water.

Next in importance to selecting a fitting season is the preservation of the roots of transplanted trees. Too much care cannot be bestowed on this division of the operation, as the former is of little consequence if the latter is neglected. Every minute fibre of the roots should if possible be saved, as it is by them alone that nourishment is taken up and as they are mostly produced at the circumference of the circle formed by the roots, the earth should be removed at some distance from the tree so as to ensure as many as possible being taken up entire. A convenient method of procuring a large supply of young fibres near the base of the stem is, either to dig a trench round the tree some months before removal by which all the principal roots are cut across, or to cut back the principal limbs, the extremities of which will emit abundance of fibres, which can then be removed uninjured in a moderate ball of earth. As the large roots when torn and bruised in the operation, are apt to lose their vitality and decay, and become the seat of disease that may ultimately destroy the tree, they should all be cut clean off when the wound will heal kindly.

These remarks are applicable to the transplanting of trees or shrubs: the same principles apply to the transplanting of succulent vegetables, which are usually transplanted two or three times to force them to throw out large quantities of fibrous roots and thereby augment their absorbing power.

In transplanting from pots or boxes into the open ground, for early crops of vegetables, the plot ought to be prepared for their reception by being first thoroughly moistened and cooled, which is effected by copiously flooding it daily, for two or three days before, and shading during the heat of the day, the same as if the plants were already there.

The practice of pruning trees when transplanted is one of doubtful propriety except to a limited extent. The reason of this is that the formation of roots depends on the healthy action of the leaves, and the renovation of the injured ones will be only in proportion to the healthy action of leaves and buds, their removal therefore is opposing an obstacle to this renovation. The danger to be feared is that the perspiration

of the leaves may exhaust the fluids faster than the roots can replace them. In such cases pruning is necessary, but should be sparingly practised and if transplanting has been well performed will not be required.

*On the saving of seed and acclimating plants.*—We mentioned above that some kinds of seed, saved in this country, give more certain and better crops than that brought from Europe, even though the latter was ascertained to be of good quality by the freedom with which it vegetated. This fact renders it desirable that attempts should unceasingly be made to procure Indian raised seed for use in India, as success in this operation holds out the only prospect of obtaining the long sought desideratum—constant supplies of good table vegetables. We also mentioned above, that to make plants flower and produce fruit it is requisite to store their systems with well digested nutritious juices: to effect this we must reduce their luxuriance by stinting their supplies of water, and giving them a poorer soil to grow in.

Any attempts to procure seed from European plants in this country, must be conducted on these principles, and with much care, as we have an almost, if not actually, insurmountable barrier to overcome in the heat of the climate, which, though it may not be such, as to prevent the plant arriving at perfection as a succulent vegetable, yet may altogether prevent its showing flower or maturing fruit. Such has hitherto been the case with our knoll-kolls, cabbages, cauliflower, celery, &c. though all seed freely on the Neilgherries. Not so however at Bangalore, the mean temperature of which is much below that of Madras. The failure at Bangalore is probably owing to imperfect management, and may ultimately be overcome, but until success has crowned their efforts and we are enabled to work with seed raised, in that comparatively warm climate, we can scarcely hope for success in the Carnatic, though that ought not to be a bar to our trying. With this view we would recommend, as the most probable method of attaining success that some of the best cabbages, knoll-kolls, &c., be transplanted into pots filled with soil composed of two parts sand, one part red loam and one part vegetable mould, and for some time watered with liquid manure, prepared by steeping dung in water, until they have recovered from the operation of transplanting. They should then be allowed to rest through the hot season, merely giving water enough to keep them alive until Oct. They might then be planted out and liberally watered for a few times with liquid manure, until they show signs of throwing up a flower stalk, when their supplies ought to be diminished, themselves protected from the monsoon rains, and the seed ripened in the course of the cool season. It seems probable

that many failures, even in Bangalore, must be submitted to, before we obtain good seed; but the object is well worth the trouble, and it seems even probable, that if we bring the subject to the notice of European gardeners they could lend us very important assistance by obtaining seed from the warmer countries of Europe, and growing a few plants raised from them in their hot houses, until they have ascertained that under the skilful management of the English gardener these plants can be made to produce seed in a tropical temperature, when we, whatever might have been the amount of previous discouragement would probably resume our experiments with renewed energy determined to succeed as well as they.

Here we bring our hints to a close: not however without expressing the hope that they may prove useful to a few at least of our readers and that some of these may be induced to favour us with communications explanatory of the results of their experiments, the better to enable us to correct, in future editions, any errors into which we may have fallen in this. Before finally concluding, we think it necessary to state, that nearly the whole matter of these hints is derived from the work several times referred to in the course of them; namely 'LINDLEY'S THEORY OF HORTICULTURE,' the object of which is to explain on Physiological principles, the principal operations of gardening,—a work of sterling merit, and as being the only one in which a lucid explanation of the principles of gardening is to be found, one which we would strongly recommend to the especial attention of all those desirous of becoming acquainted with the Philosophy of Horticulture, unencumbered with the verbose details of practise, too often erroneous, which constitute the bulk of most of the existing works on gardening.

For those desirous of obtaining practical details, applicable to Indian Horticulture, we would strongly recommend Mr. Speed's Handbook of gardening, recently published in Calcutta, and so favourably received there, that the first edition was exhausted in a few weeks. The printing of a second edition, with many improvements, we are happy to add, is already far advanced, and will, we believe, be published nearly as soon as these Hints.—*Madras Almanac*, 1841,

*Agriculture of the Chinese.*—In order to understand Chinese agriculture, says Mr. Fortune, a knowledge of the elements of the country is of course necessary. The dominions of the Emperor of China stretch over twenty-three degrees of latitude—from 18° north, and from the 98° to the 120° of east longitude, thus including both tropical and temperate regions in its vast extent. Being placed on the east side and forming part of the large continent of Asia, it is liable to extremes of temperature—to excessive heat in summer and extreme cold in

winter—which are unknown in many other parts of the world within the same parallels of latitude. One of our best writers upon China makes the following very sensible remarks on this subject:—"Although Peking is nearly a degree to the south of Naples—the latitude of the former place being 39° 54', of the latter 40° 50' the mean temperature of Peking is only 54° of Fahrenheit, while that of Naples is 63°. But the thermometer at the Chinese capital sinks much lower during the winter than at Naples, so in summer does it arise somewhat higher; the rivers are said to be frozen for three or four months together, from December to March; while during the last embassy, in September, 1816, they experienced a heat of between 90° and 102° in the shade. Now it is well known that Naples, and other countries in the extreme south of Europe, are strangers to such a degree of long-continued cold, and not often visited by such heats. "Europe," observes Humboldt, "may be considered altogether as the western part of a great continent, and therefore subject to all the influence which causes the western sides of continents to be warmer than the eastern; and at the same time more temperate, or less subject to excesses of both heat and cold, but principally the latter."

From my own tables, he continues, kept by Newman's best registering thermometers, I find that at Hong-kong, in the months of July and August—the two hottest months in the year—the mercury frequently stood as high as 90°, and one day at 94° Fahr. in the shade. The minimum was generally about ten degrees lower than the maximum. In the winter, from December to March, the thermometer frequently sinks nearly down to the freezing point, and sometimes, although rarely, snow has fallen at Canton and on the adjacent hills. The influence of the sea, however, in this part of the Empire, has a tendency to check the extremes of both heat and cold, but these are much greater in the northern interior. The northerly winds in the winter and spring months are severely cold in the south of China, indeed, I have suffered more from cold at Hong-kong and Macao in the month of February, than I have ever done in England.

At Shanghai, in the province of Keangsoo, in latitude 31° 20' north, the extremes of heat and cold are much greater than what we experienced in the southern provinces. Through the kindness of Dr. Lockhart, who kept up my meteorological tables during my absence in different parts of the country, I have obtained a very complete set of observations for nearly two years. From these it appears that in July and August the heat is the greatest, the thermometer in the shade sometimes standing for several days at 100° of Fahrenheit. The heat during these days was almost insupportable to Euro-

peas, who, when I was in Shanghai, were obliged to live in Chinese houses, which from their construction, were ill calculated to exclude the heat. In the end of October the thermometer sometimes sinks as low as freezing point. In the evening of the 28th of that month in 1844, the remains of the cotton and other tropical plants which are cultivated in the fields during the summer were destroyed by frost. December, January, and February are the coldest months in the year, the cold then being quite as severe as it is in the South of England. In the winter of 1844—45, the thermometer sunk as low as 26° Fahrenheit. On the night of the 18th of December and again on January the 4th the index was left at 24°. But that winter, according to Chinese accounts, was peculiarly mild, so much so, that the usual supply of ice could not be procured. In ordinary years the ponds and canals are frequently frozen several inches in thickness, and afford a plentiful supply of ice. I have therefore little doubt that in most years the thermometer may be found at least 20 degrees below the freezing point or at 12° of Fahrenheit, and perhaps even lower. Snow frequently falls, but the sun is too powerful to allow it to lie long on the ground.

If we except the extremes of heat and cold just noticed, the climate of Shanghai may be pronounced as fine as any in the world. Even the cold in winter is highly advantageous to the Natives, and still more so to Europeans and Americans, as it strengthens their constitutions and enables them to withstand the effects of the excessive heat. The months of April, May and June are delightful, and although the sun is hot in the middle of the day, in the afternoon the air is soft and agreeable and the evenings cool and pleasant. The autumnal months are generally of the same description, the wind then is cool and bracing and the sky is much clearer than in England. The sun, for days, and sometimes for weeks together, rises in the morning, runs his course and sets again in a clear and cloudless sky.

The prevailing winds blow from the South West from the end of April to the middle of September, during the remaining portion of the year they are northerly and easterly: thus forming what are called the South-west and North-east Monsoons. These monsoons blow with great regularity in the South of China, but are more variable towards the North. In the latitude of Chusan or Shanghai, although the monsoons prevail, the wind, not unfrequently, blows from other quarters. In the end of the summer season, that is from July to October, the country is frequently visited by those dreadful gales called by foreigners typhoons. The name, says Fortune, is a corruption of the Chinese word Ta-fung or "great wind." These storms commit the

most fearful ravages both by land and sea. The barometer gives warning some hours before the gale commences, and therefore, foreign ships can always send down their masts and yards, and if possible, remove to a safe anchorage. Where this is not to be had, they have the dreadful alternative of standing out to sea. The Chinese without the aid of the barometer, can tell when the Ta-fung is coming by the following signs. The wind, which blows from the South-west in the typhoon season, changes and blows from the North or North-East, becoming gusty and gradually increasing in strength, the sky lowers and looks wild, the sea rolls in upon the beach with a dead heavy swell, and every thing portends a coming storm. When these signs appear, the fleets of fishing-boats on the coast take their nets in, crowd all sail, and make for the shore as fast as they can, where the boats are hauled up on dry land or into some creek which is sheltered from the force of the winds and waves. The coasting Junks, which are ill fitted for bad weather, lose no time in getting into some sheltered part where they can ride out the storm in safety. And luckily, as a safeguard from the fury of these winds, nature has provided a great number of excellent well sheltered harbours on the coast of China, all of which are well known to the pilots who are employed on board the Junks.

During my residence in China, says this author, I witnessed two of these terrific gales—once at sea, and once on shore, luckily in the first instance, we were able to run into a deep bay, and with three anchors down rode out the gale in perfect safety. The other occurred on the 21st and 22nd August, 1844, when I was at Ningpo. I observed the Chinese running about in great consternation, and calling to each other that the "great wind" was coming, and to make preparations for it. Mats and rattan work, which had been placed over the doors and windows to afford shade from the sun, were hastily removed, and many of the houses, which were known to be in a weak state, were in a rapid way, propped up and strengthened. Nor were the husbandmen less busy in the fields. The heads of the tall millet, being nearly ripe, were quickly cut, and the long stalks left to be reaped at another time. Millet is so heavy when nearly ripe, that had it been left exposed to the wind it must have been dashed to pieces, and the crop entirely lost. Crops on the sides of the rivers and canals were removed; where it was possible to do so, otherwise, they would have been blown into the water and carried away far beyond the reach of their owners. All the fruit which was nearly ripe was hastily gathered from the trees, unnecessary branches were cut away, and others tied up and supported.

## AGAR-AGAR.

The gale gradually increased in force until daylight on the morning of the 22d, when it seemed to be at its height. In Mr. Mackenzie's house, where I was staying at the time, we passed a fearful night. The wind howled and whistled round the roof, every blast seemingly more fierce than that which preceded it, until I really thought we should have the building down upon us and be buried in the ruins. At daylight the ~~rooms~~ presented a dismal appearance: all the floors, chairs, and tables were covered with dust and pieces of broken tiles and mortar which had been shaken out of the roof. As the storm still raged with unabated fury, Mr. Mackenzie and myself, glad to escape from the wreck by which we were surrounded, went out to see what effect the gale was producing on the other places in the vicinity. The wind was so powerful that it was next to impossible to keep our feet; in fact, we were frequently blown off the path and were obliged to scramble back to it again on our hands and knees. The river which is generally beautiful and smooth, had now risen and completely overflowed its banks, having been forced back by the strength of the wind and was as rough as the sea itself. The whole country was one vast sheet of troubled water for the branches of the river and the numerous canals by which it is intersected, had all overflowed their banks and had spread in the low paddy fields. Most of the small boats were safe, as they were either in sheltered creeks drawn up beyond the reach of the water, but many of the large wood-junks which frequent this port were not so fortunate. These had been moored off the city, having as usual, a large portion of their cargo lashed to their sides. In many instances, the combined force of the winds and waves snapped the lashings strong as they were, and the spars of wood floated from their sides, and were either carried away by the force of the stream or thrown on shore. Hundreds of the Chinese were now ready to seize the wood as it floated to land, and with a total disregard to the "rights of property" conveyed it at once to their own houses. No Mandarin or other Government officer interfered to prevent this, and the Chinese servants of the English Consul and other foreign residents actually brought a considerable quantity to the houses of their Masters, and seemed surprised when reproved for their dishonesty. The English of course honorably returned the spoil to its owners, much to the surprise of the Chinese.—*Fortune's Wanderings*, pages 276 and 284.

(65) AGAR-AGAR. *GRACILLARIA SPINOSA*. This is one of the Algæ, of the order Rhodophyta, and seems to have as synonyms, *Gigartina tenax* also *Gracillaria tenax* also *Fucus tenax* of Turner. Mr. Williams and the honorable Mr. Morrison say of the *Gigartina Tenax*, that the Chinese people collect

## AGATI GRANDIFLORA.

this sea-weed on the coast to a great extent using it in the arts and also for food. The *Gigartina tenax* is prepared as affording an excellent material for glues and varnishes. It is boiled and the transparent glue obtained is brushed upon a porous kind of paper called "*shachi*" which it renders nearly transparent. It is also used as a size for stiffening silks and gauze, and extensively employed in the manufacture of lanterns and in the preparation of paper for lattices and windows. This and other kinds of fuci are boiled down to a jelly by the islanders on the south and extensively used for food, it is known in commerce under the name of *agar-agar*.—*Williams*, p. 275. The honorable Mr. Morrison says, *Gracillaria tenax*, is the *Fucus tenax* of Turner; about 27,000 lbs. are annually imported into Canton, from the provinces of Fokien and Tehi-Kiang, and sold for 6d. to 8d. the pound. The Chinese make it the basis of an excellent glue and varnish, and employ it chiefly in the manufacture of lanterns, to strengthen or varnish the paper and sometimes to thicken or give a gloss to silks or gauze. Mr. Neill thinks that the gummy substance called Chin-chou, or hai-tsai, in China and Japan may be composed of this substance. Windows made of slips of Bamboos and crossed diagonally, have frequently their interstices wholly filled with the transparent glue of hai-tsai.

(66) AGATHOTES CHIRAYTA (Don); *Ophelia chirayta*, (Grisebach); *Gentiana chirayta* (Fleming); Beng. and Hind. *Chirata*; grows in Nepal, the north of India, and Morung Hills. All parts of the plant are extremely bitter and are identical in composition with the common gentian. It is highly esteemed as a tonic and febrifuge all over India. The *Ophelia chiretta* is a common and abundant plant in the bazar, supplied chiefly by the lower ranges of the Himalayas.—*Dr. Cleghorn*. This well known Indian bitter is a common Burman medicine, but Mr. Mason had never seen the plant growing. It is considered a good substitute for cinchona, but it frequently acts as an aperient as well as a tonic. It is often confounded with another bitter, *kreet*,—*Justicia paniculata*.—*Mason*.

(67) AGATI GRANDIFLORA, Syn. *ÆSCHYNOMENE GRANDIFLORA*

Buka, SANS.	Basua, HIND.
Buka angusta, BENG.	Avesi, TEL.
Agati, TAM.	

Very common in India; the bark is said to be a powerful bitter tonic. The leaves are aperient.—*O'Sh.* p. 296. A small delicate tree, from twenty to thirty feet high, of only a few years duration. It is generally found in the vicinity of villages, where the natives encourage its growth, for the sake of the leaves and tender pods which they use in their curries. It is in flower and fruit most part of the year. The tree

## ATMOSPHERIC AIR.

is employed for training the Betle plant (*Piper betel*) it admits the sun's beams, and the wind, better than any other of its height, being thin of branches and leaves, particularly after it is more than one year old. It is of a very quick growth, which is another reason for employing it. The wood is only fit for fuel. Cattle eat the leaves and tender parts.—*Rhode, M.S.S.*

(68) *AGLAI A ODORATA*. Amongst other plants worthy of notice cultivated by the Chinese are their cinnamon, the pretty *Aglai a odorata*, and *Murraya exotica*, both of which are very sweet scented and much cultivated by the Chinese.—*Fortune's Tea Districts, p. 7.*

(69) *AIIOO*. A soft, though fine, but not very close grained, light Ceylon wood.

## (70) ATMOSPHERIC AIR.

Air Atmosphérique. FR.	Atmosphärische Luft. GER.
Howa, ARAB. HIND. and	Ahvee, TAMUL.
PERS.	Agassium, TEL.
Bad, PERS.	

The Atmosphere, which everywhere surround the globe, extends to a height of 45 miles.

“ The vital air  
Pervades the swarming seas and heaving earths,  
Where teeming nature broods her myriad births;  
Fills the fine lungs of all that breathe or bnd,  
Warms the new heart, and dyes the gushing blood;  
With life's first spark inspires th' organic frame,  
And as it wastes, renews the subtle flame.”

It is an invisible gaseous body, devoid of odour and of taste, compressible, easily expanded by heat. Its Sp. Gr., according to the experiments of Sir G. Shuckburgh, is 0.01208 at 60° Fahr., and the Barometrical pressure of 30". But being usually taken as the standard of comparison for gases, it is then commonly reckoned = 1.100 Cubic Inches weigh 31.0117 grains, and its pressure at the level of the Sea is equal to 15 pounds upon each square inch of surface, or a column of air one inch square, and extending to the limits of the atmosphere, weighs about 15 pounds, or the same as a column of Mercury, also one inch square, but only 30 inches high, which it is thus able to balance and support by the pressure of its weight. This weight must necessarily vary at great depths, as well as at great heights, as a greater or less mass of air will be superimposed. Hence the Barometer is employed for measuring heights, a diminution of one inch being found equal to about 1000 (922) feet. From being compressible, its density necessarily varies at different heights, the inferior strata being dense, and the upper ones rarefied. The temperature also diminishes as we ascend into the atmosphere, at the rate of 1° F. for every 100 yards, or, more correctly, for every 352 feet.

Though apparently simple in composition, it is actually composed of two very distinct gaseous bodies, Oxygen and Nitrogen, and a small por-

## ATMOSPHERIC AIR.

tion of Carbonic Acid gas. The proportions in which these exist are:

Nitrogen gas	77.5 by measure,	75.55 by weight.
Oxygen gas	21 " "	23.32 " "
Aqueous vapour	1.42 " "	1.03 " "
Carbonic Acid gas	.08 " "	.10 " "

Omitting the aqueous vapour, which is variable in quantity, sometimes amounting, in hot countries, to as much as 2 per cent., the proportions of the permanent gases are stated by Humboldt, from experiments by himself and Gay Lussac, to be:

Nitrogen gas	- - - - 0.787 by measure.
Oxygen gas	- - - - 0.210 " "
Carbonic Acid gas	- - - - 0.003 " "

or, omitting the Carbonic Acid gas, 77 by weight of Nitrogen, with 23 of Oxygen, or by volume 79.2 of the former and 20.8 of the latter, in 100 parts.

The presence of Ammonia, in small quantities, has been detected by Liebig; and some Nitric is found also after thunder-storms. It has been imagined that some Hydrogen gas may exist in atmospheric air; and Muriatic Acid, it is said, has been detected in it at the sea-shore.

Dr. Murray has observed, that the Atmosphere may be regarded as a collection of all those substances which are capable of existing at natural temperatures in the aerial form, and which are disengaged by the processes carrying on at the surface of the earth. These, with other substances, as watery vapour, the effluvia from animals and vegetables, independent of Heat, Light, and the Electric fluid, form a vast mixture, the composition of which it is apparently impossible to determine.

Chemical Analysis has, however, proved that the various substances which may be mixed with the atmosphere quickly disappear, and are not to be detected by Chemical Tests, and that the composition of the air is everywhere uniform. It must, however, be admitted, that in very crowded assemblies of people, where there is a want of circulation, the quantity of carbonic Acid gas is a good deal increased. It was at one time supposed that the constituents of the Atmosphere were retained by Chemical Attraction. Dalton, however, promulgated the opinion, that they were mechanically mixed, that the particles of the same gases repel, but that the particles of different gases do not repel, one another; and that thus one gas acting as a vacuum to another, and each being repelled by its own particles, they become diffused. Professor Graham has ascertained that each gas has a diffusive power, or *Diffusiveness*, peculiar to itself, which is inversely proportional to the square root of its density.

The properties of Atmospheric air are a mean of those of its constituents, and its che-

## ALANGIUM DECAPETALUM.

mical actions are due to the oxygen; by this it is enabled to support combustion; also the respiration of animals, a portion of it being by them converted into Carbonic Acid. Fishes also depend upon its presence in the water, though this dissolves only a small portion of the air, but more of its Oxygen than of its Nitrogen. The processes of vegetation are also dependent upon the atmosphere, as it conveys water and also Carbonic Acid to the leaves of plants, where the Carbon becomes fixed, and the Oxygen again set free; and thus plants contribute to purify the air which might become deteriorated by the respiration of animals. As the atmosphere varies in the quantity of moisture it contains, so it assists in the distribution of water over the surface of the globe, and is, by its nobility, the principal agent by which the extremes of temperature are moderated. According to the temperature and moisture of the atmosphere, so is the rate of evaporation, and consequently of perspiration. Hence not only many pharmaceutical preparations require a knowledge of the constitution of the atmosphere, but some of the functions of the body must be influenced by its different states, and the operations also of some classes of medicines are modified by its different degrees of density and of dryness.—*Royle, Mat. Med. p. 22.*

(71) ACHEEN. This monarchy arose from the usurpation of Sultan Saleh-ood-din in A. D. 1521, previous to which time, Acheen had been a province of Pedir and governed by a viceroy from that kingdom.—*Journ. Ind. Arch.*

(72) AKAKIYA, A red stone brought to Ajmere from Delhie containing iron; is used as a tonic, in the dose of one tola; one seer for two rupees.—*Genl. Med. Top. p. 125.*

(73) AKHIREE CHAR SHUMBAH, A feast held amongst Mahomedans on the last Wednesday of their second month Saffur.—*Herklots.*

(74) AKUT CHOONI. Small rubies or garnets. Are brought via Pali to Ajmere and used as an aphrodisiac: one tola for two rupees.—*Genl. Med. Top. p. 125.*

(75) ALCEDO ISPIDA, THE KINGFISHER.

"The alcyon flew across the stream,  
And the silver brooklet caught the gleam.  
The glittering flash of his dazzling wings  
Was such as the gorgeous rainbow flings."

A native of Coromandel, Malabar, and Bengal, flowers during the hot season, the wood is beautiful.—*Roxb. Rhod. M. S. S.*

(78) ALIAKOO. MEMECYLON TINCTORIUM.

(79) ALGÆ. ORDER, FUCACEÆ (ALGACEÆ, Lindl. Nat. Syst. p. 430.—Algæ, Juss. The Sea-weed Tribe. Of these leafless, flowerless water-plants, Wallich's Catalogue only enumerates two Indian species, borrowed from Buchanan's Herb. Royle mentions none, but says that Rottler's Herb. contains a few species of *Conferva* collected from the neighbourhood of Tranquebar.—*Voigt. Hort. Sub. Cul.* Dr. Hooker gives what the Rev. M. J. Berkeley, has written on the Indian Algæ which occur principally in different parts of the Himalayan Range, in the hot-springs of Soorujkoond in Bengal, Pugha in Tibet, and Momay in Sikkim; and on the Fungi of the Himalayas.

The Algæ from lower localities are but few in number, and some of them of very common forms. We have for instance from the Ganges, opposite Bijour, a *Batrachospermum* and *conferva crispata*, the former purple below, with specimens of *Chantransia*, exactly as they might occur in the Thames. The *Conferva*, or more properly *Cladophora*, which occurs also under various forms, at higher elevations, as in the neighbourhood of Simla and Iskardo, swarms with little parasites, but of common or uninteresting species. In the Bijour specimens, these consist of common forms of *Synedra*, *Meridion circulare*, and a *Cymbella*, on others from Dacca, there are about three species of *Synedra*, a minute *Navicula* and *Gomphonema curvatum*. Nothing, in fact, can well be more European. One splendid Alga, however, occurs at Fitcoree, in Behar, on the banks of nullahs, which are dry in hot weather, forming a purple fleece of coarse woolly hairs, which are singularly compressed, and of extreme beauty under the microscope, from the crystalline green of the articulated string which threads the bright red investing sheath. This curious Alga calls to mind in its colouring, *Cœnocoleus Smithii* figured in English Botany, t. 2940, but it has not the common sheath of that Alga, and is on a far larger scale. One or two other allied forms or species, occur in East Nepal, to which Dr. Hooker purposes giving, together with the Behar plant, the generic name of *Erythronema*. From the Soane River, also, is an interesting Alga,

belonging to the curious genus *Thwaitesia*, in which the division of the endochrome in the fertile cells into four distinct masses, sometimes entirely free, is beautifully marked. In some cases, indeed, instead of the ordinary spores, the whole mass is broken up into numerous bodies, as in the fertile joints of *Ulothrix*, and probably, as in that case, the resultant corpuscles are endowed with active motion. In Silhet, again, is a magnificent *Zygnema*, allied to *Z. nitidum*, with large oval spores, about  $\frac{1}{8}$  part of an inch long, and a dark golden brown colour, and containing a spiral green endochrome.

Leaving, however, the lower parts of India, the species which occur in Khasia, Sikkim, Eastern Nepal, and the adjoining parts of Tibet, may now be taken. In the hot valleys of the Great Rungeet, at an elevation of about 2000 feet, we have the *Erythronema*, but under a slightly different form; at Nunklow, at about the same height; in Khasia, again, at twice that elevation; in Eastern Nepal, at 12,000; and, finally, at Momay, reaching up to 16,000 feet. In water, highly impregnated with oxide of iron, at 4,000 feet in Sikkim, a *Leptothrix* occurred in great abundance, coloured with the oxide, exactly as is the case with Algæ which grow in iron springs in Europe. At elevations between 5000 and 7000 feet, several European forms occur, consisting of *Ulothrix*, *Zygnema*, *Oscillatoria*, *Lyngbya*, *Sphærozyga*, *Scytonema*, *Conferva*, and *Cladophora*. The species may indeed not be identical with European species, but they are all more or less closely allied to well-known Hydrophytes. One very interesting form, however, either belonging to the genus *Zygnema*, or possibly constituting a distinct genus, occurs in streams at 5000 feet in Sikkim, consisting of highly gelatinous threads of the normal structure of the *Zygnema*, but forming a reticulated mass. The threads adhere to each other laterally, containing only a single spiral endochrome, and the articulations are very long. Amongst the threads are mixed those of some species of *Tyndaridea*. There is also a curious *Hormosiphon*, at a height of 7000 feet, forming anastomising gelatinous masses. A fine new species of *Lyngbya* extends up as high as 11,000 feet. At 13,000 feet occurs either some simple *Conferva* or *Zygnema*, it is doubtful which from the condition of the specimens, and at the same elevation, in the nearly dry bed of the stream which flows from the larger lake at Momay, amongst flat cakes, consisting of felspathic silt from the glaciers above, and the debris of Algæ, and abounding in Diatomaceæ, some threads of a *Zygnema*. At 17,000 feet, an *Oscillatoria*, attached or adherent to *Zannichellia*; and, finally, on the bare ground, at 18,000 feet, on the Dankia mountains, an ob-

scure species of *Cænocoleus*. On the surface of the glaciers at Kinchinjow, on silt, there is a curious *Palmella*, apparently quite distinct from any European form.

Amongst the greater part of the Algæ, from 4000 feet to 18,000 feet, various Diatomaceæ occur, which will be best noticed in a tabular form, as follows; the specific name within brackets, merely indicating the species to which they bear most resemblance.

Himantidium (Soleirolii) .....	4000 to 7000 feet.	Sikkim
Odontidium (hiemale, forma minor) .....	5000 to 7000 "	" "
Epithemia, n. sp. ....	7000 "	" "

Epithemia (ocellata) .....	—	" "
Fragillaria .....	18,000 "	Momay.
Odontidium (turgidulum) .....	—	" "
Dictyocha (gracilis) .....	—	" "
Odontidium (hiemale) .....	—	Kinchinhow

In those portions of Tibet and the neighbouring regions, explored by Dr. Thomson and Captain Strachey, the principal feature in the Algology is the great prevalence of species of *Zygnema* and *Tyndaridea*, which occur under a variety of forms, sometimes with very thick gelatinous coats. In not a simple instance however, is there the slightest tendency to produce fructification. *Conferva crispata* again, as mentioned above, occurs in several localities; and in one locality a beautiful unbranched *Conferva*, with torulose articulations. At Iskardo, Dr. Thomson gathered a very gelatinous species of *Draparnaldia*, or more properly, a *Stygeoclonium*, if we may judge from a little conglomeration of cells which appeared amongst the threads. A *Tetraspora* in Piti, an obscure *Tolypothrix*, and one or two *Oscillatoria*, remarkable for their interrupted mode of growth, complete the list of Algæ, with the exception of one, to be mentioned presently; as also of *Diatomaceæ*, and of the species of *Nostoe* and *Hormosiphon*, which occurred in great profusion, and under several forms, sometimes attaining a very large size (several inches across), especially in the districts of Le and Piti, and where the soil or waters were impregnated with saline matters. It is well known that some species of *Nostoe* form an article of food in China, and one was used for that purpose in a late Arctic expedition, as reported by Dr. Sutherland; but it does not seem that any use is made of them in Tibet, though probably all the large species would form tolerable articles of food, and certainly, from their chemical composition, prove very nutritious. One species is mentioned by Dr. Thomson as floating, without any attachment, in the shallow water of the pools scattered over the plains, on the Parang River, separated only by a ridge of mountains from Piti, broad and foliaceous, and scarcely

different from the common *Nostoe*, which occurs in all parts of the globe. A very singular new genus, which the young threads have the characters of *Tyndaridea*, but, after a time, little swellings occur on their sides, in which a distinct endochrome is formed, extending backwards into the parent endochrome, separated from it by a well defined membrane, and producing either by repeated pullulation, a compound mass like that of *Dactylaria* or simply giving rise to a forked thread. In the latter case, however, there is no external swelling, but a lateral endochrome is formed, which, as it grows, makes its way through an aperture, whose sides are regularly inflected. He has given to this curious production the name of *Cladozygia Thomsoni*. The whole of the above Algæ occurred at heights varying from 10,000 to 15,500 feet. As in the Southern Himalayan Algæ, the specimens were infested with many Diatomaceæ, amongst which the most conspicuous were various *Cymbellæ* and *Epithemiæ*. The following is a list of the species observed.

<i>Cymbella (gastroides).</i>	<i>Synedra (arcus).</i>
— ( <i>gracilis</i> ).	— ( <i>tenuis</i> ).
— ( <i>Ehrenbergii</i> ).	— ( <i>qualis</i> ).
and three others	<i>Denticula (obtusula).</i>
<i>Odontidium (hiemale).</i>	<i>Gomphonema (abbreviatum).</i>
— ( <i>mesodon</i> ).	<i>Meridion circulare.</i>
<i>Epithemia n. sp.</i>	

There is very little identity between this list and that before given from the Southern Himalayas, as is the case also with the other Algæ. Till the species, however, have been more completely studied, a very accurate comparison cannot be made. In both instances the species which grow in hot springs have been reserved in order to make their comparison more easy. I shall, he says, begin in an inverse order, with those of the springs of Pugha in Tibet, which attain a temperature of 174°. Two *Conserve* only occur in the specimens which have been preserved, viz., an *Oscillatoria* allied to that which he has called *O. interrupta*, and a true *Conserve* extremely delicate with very long articulations, singularly swollen at the commissures. The Diatomaceæ are.

<i>Odontidium (hiemale).</i>	<i>Denticula (obtusula).</i>
— ( <i>mesodon</i> ).	<i>Navicula.</i>
— n. sp. same as	<i>Cymbella</i> , three species.
Pition <i>Conserve</i> .	<i>Epithemia.</i>

Scarcely any one of these except the *Navicula* is peculiar to the locality. A fragment apparently of some *Closterium*, the only one which he met with in the collection, accompanies one of the specimens. The hot springs of Momay, (temp. 176°) at 16,000 feet, produce a golden brown *Cænocolens* representing a small form of *C. cirrhosus*, and a very delicate *Sphærozyga*, an *Anabaina* and *Tolypothrix* and at 17,000 feet, a delicate green *Conserve*; with long even articulations. With the latter is an *Odontidium*

allied to or identical with *O. turgidulum*, and with the former a fine species of *Epithemia* resembling in form, but not in marking, *E. Faba*, *E. (Zebra)* a fine *Navicula*, perhaps the same with *N. major* and *Fragilaria (virescens)*. In mud from one of the Momay springs (a), he detected *Epithemia (Broomelii n. s.)*, and two small *Naviculæ* and in the spring (c) two species of *Epithemia* somewhat like *E. Faba*, but different from that mentioned above.

The hot springs of Soorujkoond, of the vegetation of which very numerous specimens have been preserved, are extremely poor in species. In the springs themselves and on their banks, at temperatures varying from 80° to 158°, at which point vegetation entirely ceases, a minute *Leptothrix* abounds everywhere, varying a little in the regularity of the threads in different specimens, but scarcely presenting two species. Between 84° and 112° there is an imperfect *Zygnema* with very long articulations, and where the green scum passes into brown, there is sometimes an *Oscillatoria*, or a very minute stellate *Seytonema*, probably in an imperfect state. *Epithemia ocellata* also contributes often to produce the tint. An *Anabaina* occurs at a temperature of 125°, but the same species was found also in the stream from the springs where the water had become cold, as was also the case with the *Zygnema*. Mr. Thomas Brightwell finds in a portion of the same specimen *Epithemia alpestris*.

The Diatomaceæ consisted of—

<i>Epithemia Broomelii</i> , n. s.	<i>Epithemia inæqualis</i> , n. sp.
— thermalis. n. sp.	<i>Navicula Beharensis</i> . n. sp.

The vegetation in the three sets of springs was very different. As regards the *Conserve*, taking the words in its older sense, the species in the three are quite different, and even in respect of genera there is little identity, but amongst the *Diatomaceæ* there is no striking difference, except in those of the Behar springs where three out of the four did not occur elsewhere. In the Pugha and Momay springs, the species were either identical with, or nearly allied to, those found in neighbouring localities, where the water did not exceed the ordinary temperature. A longer examination will doubtless detect more numerous forms, but those which appear on a first examination are sure to give a pretty correct general notion of the vegetation. The species, he adds, are certainly less numerous than he had expected, or than might be supposed from the vegetation of those European hot springs which have been most investigated.—*Hooker, Him. Jour. Vol II. page. 381.*

(80) ALLIGATOR. Dean French in his study of words (page 125) says "when the alligator, this ugly crocodile of the new world, was first seen by the Spanish discoverers, they called it, with a true insight into its species, "el

## ALOE FAMILY.

lagarto," or the lizard; as being the largest of the lizard species to which it belonged.

(81) ALLOYS. The natives of India are acquainted with a variety of alloys for making utensils and even ornaments, as with copper and zinc, tin and lead, besides being great workers in copper and brass for the various utensils employed for domestic purposes, and of which so large a variety was sent from different parts of India.—*Royle Arts &c. of India*, page 471.

The following is a memorandum of Drs. Wight and Porteous on the subject of alloys of copper in use in the district of Coimbatore.

The metals employed in the formation of these alloys are copper—zinc—tin—and lead in the following proportions.

1. Copper 10 parts Zinc  $6\frac{1}{2}$ . Alloy valued at 4 annas per seer of 24 tolas weight and is used for all purposes.

2. Copper 10 parts zinc 5—Alloy valued at  $3\frac{1}{2}$  annas per seer, somewhat darker than the other, but considered equally useful.

3. Copper 10—zinc 10—Alloy valued at 3 annas the seer considered inferior to the others, but is also in current use.

4. Copper 10—tin  $2\frac{1}{2}$ —A beautiful bell metal alloy, valued at 6 annas the seer. Is used for the same purposes as the others.

5. Copper 10—tin 2—lead  $\frac{1}{2}$ —An inferior looking alloy to the former but is employed for similar purposes, price not mentioned.

These metals are all imported and are procurable at the following prices in the bazar, copper per seer 5 annas—zinc 1 anna 4 pic—tin 4 annas—lead 1 anna 4 pic.

A vessel of No. 4 was by far the finest of the series, and when gently struck gave out a fine bell sound.

A small piece of this alloy was prepared in their presence. This sample whether owing to some imperfection of the preparation or to the smallness of the mass (5 Rupees weight) did not seem equal to the vessel exhibited, and was found so hard as to be exceedingly difficult to work.—*M. O. C.*

(82) ALOE FAMILY. LILIACEOUS PLANTS.—*Agave Americana*, Common American Aloe, *Outtalay*, *Bramarachsee* Nar or *Kitha Nara*.—Some very fine specimens of this fibre were exhibited at the Madras Exhibition of 1855 by the Tanjore, Travancore, and Nellore local committees, also by Dr. Riddell from Bolarum: Mr. Underwood, Madras: Major Dobbs, Chittledroog: the Lunatic Asylum, Bangalore: Mr. Thorpe, Monegar Choultry, Madras: Assist. Surgeon H. Nott, Tranquebar: Capt. Meadows Taylor, Nizam's Territories: and the Madras School of Arts. In addition to these, there were indifferent and bad specimens of the same fibre, from almost every part of the Madras Presidency. Although this plant is not inde-

## ALOOBOA.

genous, it seems to be one of the most widely diffused in Southern India. It seems particularly well suited for cordage, and from the repeated trials which have been made with it (see "Fibrous plants of India" by J. Forbes Royle, M. D. F. R. S. 1855; Reports of experiments made in the Arsenal Fort St. George, and the Madras Journal of Arts) there is no doubt that when carefully prepared, the fibre is as strong as Russian hemp. The Aloe fibre now forms an article of export from the Western Coast; in the year 1853-54, 3,658 cwts. were exported, valued at Rs. 21,506. It was employed for several years, instead of English hemp, in the Arsenal at Madras, but it was ascertained that the fibre was liable to rot, when frequently wet, and its use was discontinued on this account. It has also been tried in the Madras Arsenal as a substitute for tow in packing shot, but is found to be more easily cut.

Further experiments, however, would probably point out some means of overcoming this defect. The Jury were indebted to Mr. Thorpe for pointing out the cause of one defect, viz. its tendency to rot, and to Mr. Underwood for suggesting a means of obviating it (See process of cleaning the fibres of Agave).—*M. E. J. R. of 1855*.

This Fibre is capable of being turned to great account and several very fair samples were exhibited at the Madras Exhibition of 1857.

The cleanest and best prepared were those of Hurry Row, No. 4,621, and No. 2,977, from J. B. Roupell, Esq., these were soft, pliant and of good strength. E. Ahobalarow exhibited a fair specimen. Kanagaroyen, Native Surgeon at Coimbatore, exhibited Aloe Fibres, dyed of good colors. These are interesting specimens, and though not coming under this section of the Jury, the Committee could not but remark some very serviceable door-mats manufactured in patterns from these colored fibres. Good clean Fibre of Aloe was exhibited by W. Elliot, Esq. of Cuddapah. On the whole the Fibre of the Agave shewed well and both Hurry Row and Ahobalarow were deemed entitled to prizes.—*M. E. J. R. of 1857*.

(83) ALOE PERFOLIATA. Vera, Linn.

Kaithaulai or Kuttalay, TAM.  
Kalabuntha, TEL.  
Koomarie, SANS.

The pulp is eaten by the natives, after having been carefully and repeatedly washed in cold water: they generally mix it with a little sugar and reckon it cooling. It is obtained from the leaf of the small Aloe—*Ainslie's Mat. Med. p. 260*.

(84) ALOOBOA. A rather soft, coarse, open-grained, but not very light Ceylon wood.

(85) ALUM.

Alum, ENG.  
Phitkarie, HIND.

## ALTHEA ROSEA.

*Alum* comes to Ajmere from Sind, where it is made; about three hundred camel loads annually arrive: red alum is brought to Ajmere from Lahore and used in medicine as an astringent; but chiefly employed in dyeing: one maund sells for ten Rupees.—*Genl. Med. Top.* p. 149.

(86) *ALPINIA ALHUGAS*: Ceylon *Alpinia*. Hind. Sans. Taruka, Tara. Found in the marshy parts of the black soil of the Kotah jungle.—*Genl. Med. Top.* p. 171.

(87) *ALPINIA NUTANS*. Nodding-flowered *Alpinia*. Pooag Chumpa. Beng. Cultivated in gardens: was brought by Dr. Irvine himself from Tark to Ajmeer: the flowers are beautiful, and the whole plant is fragrant like the cardamom: the seeds do not ripen.—*Genl. Med. Top.* p. 171.

(88) *ALSOPHILA GIGANTEA*, Wall. *Tree-Fern*. This *Alsophila* occurs at Dorjeling immediately below 6,500 feet the tree-fern appears. It is a widely-distributed plant, common to the Himalaya, from Nepal eastward to the Malayan peninsula, Java, and Ceylon.

*Alsophila gigantea* ascends nearly to 7000 feet in the outer Himalayas.—*Hooker, Vol. I.* p. 110 and 142.

(89) *ALSOPHILA SPINULOSA* is the "Pugjik" of the Lepchas, who eat the soft watery pith: this tree fern grows in Sikkim, abundant, in East Bengal and the Peninsula of India. The *Alsophila gigantea*, another Sikkim tree-fern is far more common than *A. spinulosa* from the level of the plains to 6,500 ft. elevation, and is found as far south as Java.—*Hooker Him. Jour. Vol. II.* p. 13.

## (90) ALSTONIA SCHOLARIS.

Satween or Sheitan, Hind.

*Alstonia scholaris* appears to be abundant in the Concan: and Dr. Gibson of Bombay has found it useful as a febrifuge, he published an account of its qualities about two years ago in the *Pharmaceutical Journal*; he gave it in tincture.—*Ind. Ann. Med. Sci. for April, 1856* p. 397.

(91) *AMBALAM*. (Hort Mal) *Spondias Myrobalan*, Sir William Jones—*Amrataca*, Sans.

*Ambalam* is the Malayalam name of a tree which, Rheede informs us is a variety of the *Ort Ambalam* (*Spondias Mangifera*) or *Caat Maampullum* (Wild Mango) of the Tamools. The fruit when fully ripe is of a pale yellow color of a pleasant flavour, but a little too acid. Sir William Jones tells us, that, in upper Hindoostan, it is used in cookery. See *Asiatic Researches*, Vol. IV. p. 284.—*Ainslie.* p. 221

(92) *ALTHEA ROSEA*, the parent of the many beautiful varieties of hollyhock, a native of China, yields a blue coloring matter equal to

## ALKALINE MINERALS.

(93) *ALKALINE AND EARTHY MINERALS*. Southern India is particularly rich in this class of mineral products, the origin of which seems to be the decaying granites of the country. The most common form of Alkali, is the Dhobee's Earth, a whitish grey, sandy efflorescence, which often covers miles of country where decayed white granite forms the surface soil; the earth contains from 13 to 25 per cent of crude carbonate of soda and begins to accumulate in the dry weather; immediately after the rains, it can be scraped off the surface to the depth of two or three inches, and by repeated boiling and the addition of a little quick lime, the alkali is obtained of considerable strength. With a little care very clean Carbonate of Soda can be obtained, fit for the manufacture of Toilet soap, white glass, and glazes for pottery. The crude earth in different states was exhibited at the Madras Exhibition of 1857, from almost every district. The best samples of the prepared earth were exhibited by Bauloo Moodelly, who has frequently furnished it in large quantities for manufacturing purposes. The Nellore, Cuddapah, Masulipatam and Chingleput Districts, yield this earth in great quantities, and repeated attempts have been made to prepare from it Barilla for exportation, and very fair specimens have been exported at different times, but the moderate price of the Carbonate of Soda of England, prepared from sea salt will always prevent this from being a remunerative article of export. The colored frits for Bangle glass, exhibited in another Class, have lately however become an article of export from the Madras presidency.

*Nitrate of Soda*.—Samples of this salt were exhibited from Bellary and Hyderabad where, it seems to form a natural efflorescence. Its chief use is as a substitute for saltpetre for the manufacture of Nitric and other acids and chemical substances. It is too deliquescent for making gunpowder, though it answers well for some descriptions of fireworks.

*Muriate of Soda*, mineral salt, of very fair quality was exhibited from Bangalore, Bellary and Hyderabad, and is known to occur also in the Guntoor and Nellore Districts and to be almost invariably accompanied by some interesting minerals; viz. gypsum, magnesian limestone, sandstone, sulphur, red and brown iron ores, and alum slate. As most of these minerals have come in from the districts that produce the mineral salt, it would be worth while to direct further search to be made in the vicinity for the sulphur and alum slate, both of which are valuable products. Sulphur is exhibited from several districts associated with the above and other combinations. Alum slate was also exhibited from the Cuddapah District, Vellore, and the Neilgherries, but the accompanying minerals had

## ALKALINE MINERALS.

ing description of the Salt Range in the Punjab, from the Eastern base of the Suliman Mountains to the River Jhelum in the Punjab, Lat  $32^{\circ} 30' - 33^{\circ} 20'$ , by Dr. Jameson, will show the importance of this class of formations.

The rocks in this part of the range are, (1) Magnesian Limestone, (2) New Red Sandstone, (3) fossiliferous sandstone, (4) Red Clay and sandstone containing Coal and Mineral Sulphur, Rock Salt, Gypsum, brown and red Iron ore and Alum slate. The lower beds contain no organic remains but the upper abound in them. The Iron ore is a red or brown Hæmatite, so rich that in many places the needle of the compass becomes quite useless even at a considerable distance from the rocks, owing to their being highly magnetic, from the quantity of iron which they contain. The sandstone abounds with the exuvie of enormous animals, either Saurians or Sauroid fishes.

The Hills at Kala Bagh contain great quantities of Aluminous slate, from which Alum is obtained at various manufactories in that town. The slate, well sprinkled with water, is laid in alternate strata with wood, until the pile reaches a height of 25 to 30 feet; it is then lighted and the combustion continued for about twelve hours, in which time the color of the slate is converted from greyish black to dark red. This change of color indicating that the process has been carried to a sufficient extent, the mass is thrown into a tank holding as much water as it is computed the Alum is competent to saturate. After three days the water, which becomes of a dark red color, is drawn off, mixed with a due proportion of potash and boiled down. The residuum on cooling becoming a solid mass of Alum.

A very interesting series of salts, consisting chiefly of the Muriate and carbonate of soda from the Loonar Lake in the Hyderabad territories, was exhibited in 1857, by Dr. George Smith, Residency Surgeon, Hyderabad. These have already been carefully examined by Professor Mayer and reported upon at some length in Vol. 1, New series of the Madras Journal of Literature and Science. The following is a condensed epitome of the Report and of the chemical composition of the salts.

No. 1. Dulla. This is a Carbonate of Soda with a faint trace of Muriate of Soda and about 2 per cent of impurities.

No. 2. Nimmuck Dulla. Is nearly pure Muriate of Soda.

No. 3. Khuppul. Is carbonate of Soda, with water and about 2 per cent of impurities.

No. 4. Puppre. Is nearly pure Carbonate of Soda.

No. 5. Madkhar. This is an impure salt containing Carbonate of Soda,..... 27

Clay and sand,..... 30

Water about,..... 17

Common Salt..... 25

## AMARANTUS.

No. 6. Bhooskee.

This contains Carb. of Lime, ... 78  
Carbonate of Magnesia ...  
Insoluble matter with Oxide of Iron &c. 9  
Chloride of Sodium, ... 2  
Water, ... 3

The Natron lake of Loonar occurs in the Circar of Meinker, Soubah of Berar, about 45 miles N. W. of Hingolie, in Lat.  $20^{\circ}$  N. It is about 510 feet below the level of the surrounding ground, in a kind of Crater of 5 miles in circumference; the lake being about 3 miles in circumference and surrounded by luxuriant vegetation; springs of clear soft water occur close to the lake, which has evidently been extending its bounds lately, as numerous dead trees are standing within its margin, and a bowrie of sweet water, protected by a wall, is now completely surrounded by the water of the lake. An intolerable stench of sulphuretted hydrogen is emitted by the lake during the heat of the day, and its waters prove destructive to animal and vegetable life, though flocks of duck and teal dot the surface of its waters. There are two saline springs near the centre of the Lake, and about  $\frac{1}{2}$  a mile apart. These never become dry. It is supposed that the muriate of Soda from this source, coming in contact with the Carbonate of Lime which abounds in the vicinity causes the deposition of the Carbonate of Soda or Natron Salt in a greater or less state of purity. The depth of the lake near the salt springs varies from 6 feet during the hot months to 12 or 14 feet during the rains. The salt is raised by divers, who bring it up in their hands. It is much prized and finds a ready sale in both Berars, Nagpore, Candeish, and Poonah, to which places it is carried in Bamboo baskets and retailed by dealers. The Lake has not been regularly worked since 1836, in which year 2,136 candies of the different salts were raised, valued at Rs. 60,081. In 1853 Major Johnston raised 35 candies, valued at Rs. 1,461-4-0.—M. E. J. R. of 1857.

## (94) AMARANTUS.

Nuteya, HIND.

The herb and leaves of several species of Amaranthus are used in Indian Medicine under the term Nuteya.—O'Shaughnessy.

In the Cyclopædia of India, it was mentioned that Dr. Wight had given in his Icones the considerable number of eleven species of this genus, but Voigt's Catalogue of plants enumerates twenty-six species and varieties as having

## AMUCK.

been grown in Bengal, viz. *Amarantus tenuifolius*; *polygonoides*; *polygamus*, *Blitum*, *tristis*, *campestris*, *polystachyus*, *viridis*, *lividus*, *oleraceus*, *viridis*, *ruber*, *albus*, *gigantens*, *gangeticus*, *lanceolatus*, *atropurpureus*, *tricolor*, *Melancholicus*, *fasciatus*, *hybridus*, *frumetaceus*, *retroflexus*, *candatus*, *paniculatus*, *hypochondriacus* and *spinosus*.

### (95) AMARANTHUS CAMPESTRIS. Lin.

Sirroo keeray, TAM.	Maykanada, also
Choorie key banjee, DUK.	Gunna SANS.
Tseerikoor, TEL.	

*Ains. Mat. Med. p. 257.*

(96) AMARANTUS POLYSTACHYUS, COOPPAY KEERAY, Tam. This is the *Amarantus polystachyus*. Lin.—*Ainslie*, p. 253.

### (97) AMARYLLIS AUREA. GOLDEN AMARYLLIS.

Zurd-sosan, HIND.

Cultivated in Ajmere gardens and very ornamental. Voigt gives the following species of *Amaryllis*, viz. *Belladonna*, *pallida*, *blanda*, *Josephine*, *substriata*, *Griffithiana* and *grandiflora*.—*Gen. Med. Top. p. 188.*

(98) AMBALAM, according to Edye, is the Malayala name of a wood which produces a fruit considered by the natives to be the wild Mangoe. The fruit is very acid, and as well as the wood, is of no use.—*Edye, M. & C.*

(99) AMBER, The lumps of amber forming the necklaces of women in Sikkim (called 'Poshea') are procured in East Tibet, probably from Burmah.—*Hooker Him. Jour. Vol. II. page 194.*

### (100) AMBERGRIS.

Ambergris, ENG. | Suhabiri, MALAY.

(101) AMBOYNA. The Massacre, here, occurred in 1623.

### (102) AMETHYST.

Soognndee Kulloo, TAM.	Manik, HIND.
Murtees, ARAB.	Scuandi, CYNG.

Some of these beautiful lilac coloured minerals are found in Ceylon, in the bed of the Godavery, but occur also in the West Indies, and in Bohemia.—*Ainslie.*

(103) AMOMUM. Of this genus, Voigt enumerates nine species as having been grown in the vicinity of Calcutta; viz. *cardamomum*, *angustifolium*, *aculeatum*, *maximum*, *dealbatum*, *subulatum*, *aromaticum*, *sericeum*, and *cornostachyum*.

### (104) AMOMUM CARDAMOMUM. Lin. CARDAMOM.

Yaylersie, TAM.	Yaylakooloo, TEL.
Eelachie, DUK AND HIND.	Kapalaga, MALAY.

*Ainslie's Mat. Med. p. 270.*

(105) AMUCK, MALAY; a furious reckless onset, the muck or the "run a muck" of the English.

## ANCIENT INDIA.

### (106) AMYGDALUS COMMUNIS.

*The Oil.*

Almond oil, ENG.	Badam ka tel, HIND.
Bathama nuna, TEL.	Batham yeunai, TAM.

(107) AMYRIS ACUMINATA, ACUMINATED AMYRIS AND AMYRIS NANA DWARF AMYRIS, are both abundant with several other species in the Ajmeer hills.—*Genl. Med. Top. p. 190.*

### (108) AMYRIS COMMIPHORA.

Meisakshi, HIND.	Mygashee, TAM.
Mahesakshi, TEL.	Googul, HIND.

Dr. Irvine tells us that this is a very abundant tree and shrub in the Ajmeer hills; the tree yields a gum called googul gond, used as incense and in medicine; the gum is very like myrrh; the wood is useless except to burn, and the smoke is so pungent as to make it disagreeable to use in that way.—*Gen. Med. Top. p. 190.*

### (109) ANACARDIUM OCCIDENTALE.

*The nut.*

Moondrie cottay, TAM.	Moontamamedei ghenzaloo, DUK.
Cajooke ghootlie, TEL.	Cashewnut, ENG.
Beejara Sula, SANS.	

These nuts grow at the end of the Cashoo apples, and when roasted, are very palatable and wholesome, but more so when boiled in milk. The oil between the two shells is good for marking linen. It also makes a fine black varnish, oil very caustic.

Rheede, in his "Hortus Malabaricus" tells us, that the nuts slightly toasted are supposed to excite venery, strengthen the stomach, and afford relief in cases of vomiting and nausea.—*Ainslie, p. 228.*

*The oil.*

Caju apple oil, ENG.	Moonthamanedy nuna, TEL.
Cajoo ka tel, HIND.	Moonthericotta yeunai, TAM.

(110) ANAMITE, the name of the monosyllabic language of the Cochin Chinese.

(111) ANCIENT BUILDINGS AND RACES OF INDIA.—The preservation and illustration of ancient monuments, so essential to the early history of all countries, is more particularly important in India, where, owing to peculiar causes, no connected historical relations anterior to the 12th century are in existence. It becomes, therefore, so much the more an object of importance to supply the void as far as possible from the contemporary remains of earlier periods, which now constitute almost the only records of such times. I doubt, however, says Mr. Elliot, whether the plan, of which the outlines are sketched in the Governor General's minute, is calculated to yield useful results. Large edifices and important works of the earlier ages of civilization are comparatively rare in Southern India, and none are so congregated in one neighbourhood to allow of particular places being indicated as objects of primary research.

The subjects on which light may be expected to be thrown by antiquarian research are those connected with early history, and the ascendancy of different races, the introduction and influence of religious creeds, the increase and decrease of the population, the advance of trade, manufactures and other points of statistical interest, the progress of arts, science and literature and their condition at different periods.

The two first, viz. the course of historical and religious events, are intimately connected. Some of the greatest revolutions in the social and political relations of India have been occasioned by changes of religion. It is to the implacable rancour of the sectarian zeal generated at such times that the destruction of historical data is chiefly attributable. The earliest political change to which we can go back in the history of the Peninsula is the expedition of Rama into the forests of Dandacaranya, an event coeval with the hero worship of the Pandavas, and the Myths of the Bharata and Ramayanam. The Braminical crusade of which he was the leader, scattered the aboriginal races (the Rakshasas and demons) driving some into the mountainous and forest retreats where we still find them living in barbarous freedom, and reducing others to the state of agrarian slavery in which we now see the Pariahs, Pallars, Chermars, and other degraded castes existing in the plains. Each province has its peculiar race of Helots. Each range of mountains and every tract of forests its own tribes of wild savages either wholly independent, or partially subject to their more civilized neighbours in the open country. From the Paharis (undoubtedly a remnant of the great Tamulian or Southern family) of the Rajmahal Hills on the banks of the Ganges, through the extensive regions of Gondwana, embracing the Khonds, Sourahs and Chenchers of the Eastern Ghats, the Yanadies, Iralars, Curumbars, (at one period apparently the most numerous and powerful race of all,) in the midland provinces,—to the Bedars, Maravars, Kallars and other tribes, too numerous to particularize, comprised under the general term of Malayalis, or mountaineers in the south, we find an infinite succession of races professing customs and speaking languages differing, and, in many instances, distinct, from those of the modern Hindus. The same peculiarities may be observed in several of the nomade castes roving over the plains in the more civilized portions of the country, such as the Korchewars, Wodde-wars, Yerkelwars or Pardis, &c. A careful and systematic investigation of these remains of the former population, of their customs and religious observances, &c. with the preparation of copious vocabularies of the peculiar dialects or jargons in use amongst them, are among the most important objects to which attention should be directed. The study of these outcaste tribes, of their lan-

guage, manners and customs form nearly the only available source from which we can glean a knowledge of the aboriginal inhabitants of the Peninsula.

The complete extirpation of Buddhism as the national creed, of India, constitutes another interesting subject of enquiry. We know that it was once the predominant religion when the whole of India was subject to the sway of a single sceptre, and that even after the subversion of that power, it continued, for several centuries posterior to the christian era, to be professed by a large portion of the population. A terrible persecution swept it away with all its reminiscences, so that hardly its name survives in the south, or if pronounced at all, it is uttered with fear and a shudder of aversion at the very allusion to such impiety. But, although so completely eradicated, vestiges of it are still apparent. The temples of the old faith have been consecrated to the service of the new, and the ill concealed attempts to obliterate the distinctive marks of their original dedication can still be detected. The dates and periods of many of the chief festivals, nay the very sites and objects of adoration—not excepting the celebrated fane of Jagannath itself,—have simply been transferred from the one denomination to the other. It is to the civilised and polished spirit of Buddhism that are due the suppression of living sacrifices, including the cow (and probably that of human victims, at one time apparently universal and still in use among the most barbarous races), the exchange of a vegetable for an animal diet, and other equally marked observances. The Buddhists were in fact the reformers of their age, and to their genius is due all that is great in art or science and much that is still more valuable in literature. Surely, then, a more thorough examination of their extant monuments would well repay the labor and expence of the search. Again it was the establishment of the Lingayet or Jangama sect which overthrew the powerful dynasty of the Calyan Chalukyas in the Dekhan, and the rise of the three great existing schools of Braminical philosophy (the Dwaitya, Adwaitya and Vasistadwaitya) were in like manner connected with remarkable innovations in religious belief and with changes of political ascendancy, vaguely transmitted by tradition but of which no definite written records are forthcoming, leaving a void which we can only hope to fill by the gleanings of antiquarian investigation.

The condition of the population and national resources has fluctuated not less remarkably. Whole tracts of country once thickly peopled have been abandoned to the jungle. Some of the most unhealthy spots, where malaria now reigns undisputed, and where forests, apparently the growth of centuries, have long flourished undisturbed, exhibit in the mounds of villages

tanks, pagodas, the ridges of obsolete paddy fields, the remains of crumbling temples and sculptured stones, traces of a numerous and civilized population. With these are interspersed curious tombs, cairns and sepulchral circles which have no affinity or relation to the corresponding practices of the modern inhabitants.

Another object of attention is found in remarkable institutions, distinguishing particular districts, some of which, such as tenures of land, the functions of hereditary offices, local weights, measures, accounts and other peculiar usages are in course of being swept away by the progress of modern improvement. Every province, nay often every village, has its own special customs, which must soon disappear before the generalizing influence of foreign rule, the growth of new judicial and revenue institutions, the levelling operation of the Adalat Courts and assimilating influence of revenue surveys and new systems of police. Although the exigencies of the State have caused more attention to be paid to such subjects than to most others, the nature of the investigations have partaken too exclusively of a merely utilitarian character. Many ancient forms have already been wholly displaced, though many more remain, presenting points of interest to an antiquarian eye which the mere fiscal observer passes unheeded.

The vestiges of early art are still numerous. Those connected with architecture, sculpture and painting, called into being by the exigencies of religion, always the best stimulus to works of design, have suffered more from sectarian zeal than the ravages of time, but they are widely scattered over the length and breadth of the land. Sculptured stones, fortifications, temples, works of irrigation, are found in every direction, and not only impart a knowledge of the state of science and civilization at various periods, but throw a valuable light on the other subjects of inquiry already noticed. Images of deities no longer worshipped, monumental effigies illustrative of actions and practices long forgotten, the very name and intention of which have faded from remembrance, furnish cumulative evidence of radical changes in the social system occasioned by the sweeping revolutions before alluded to. Within a short morning ride of Madras a sculptured image of Buddha may be seen lying neglected in a small village not far from the Poona-mallée road. Monumental stones commemorative of *Suttees* and the death of warriors, are also met with in the immediate neighbourhood of Madras exhibiting peculiarities of costume, ornaments, arms and implements of great interest and wholly distinct from those now in use.

The places then to which attention should first be directed as most likely to yield prominent monuments are the capitals of the earliest known Hindu dynasties. These are

### I. In the Northern Circars.

1. Chicacole and Rajahmundry, the capitals of Andhra and of a race of sovereigns anterior to the Christian æra; a more exact knowledge of these and of the early Buddhist princes of Vegi or Vegi Desam who reigned at Dara Nagara on the Kistna near Amaravati and at Vengipuram the exact site of which is not yet known, is an important desideratum only likely to be obtained from an investigation of their monumental and architectural remains.

2. The capitals of the Calinga Chalukya power at Rajahmundry, and throughout the Northern Circars. Extant sasanas and sculptured remains exhibit several alternations of superiority between them and the Gajapatis of Orissa.

3. That of the Ganapati or Kakateya dynasty at Warangul, which, though near the frontier, and properly in the Nizam's territory, was the capital of great part of the N. Circars.

4. Of the Reddies of Condavir.

N. B.—The succession of the Buddhist race by the Chalukyas of Rajahmundry, the subsequent sway of the Ganapatis, Vema Reddies and Rayels of Bijanagar, together with their contests and the various relations between them, are little known and may be amply elucidated by existing remains.

### II. In the Ceded Districts.

These formed part originally of the kingdom of the Cholas with whom they were occasionally disputed by the Calyan Chalukyas and ultimately they constituted the principal portion of the kingdom of Bijanagar or Anegundi. The capitals of the latter power were successively Bijanagar on the Tungabhadra, Penaconda and Chandragiri. The ruins of Bijanagar and Chandragiri are extensive and remarkable.

### III. In the Southern Districts.

1. An ancient aboriginal people called Curumbers are the earliest known occupants of Dravida Desam, the modern Carnatic and Coromandel. They seem to have established numerous petty principalities over the whole Peninsula, which were ultimately absorbed in the Chola empire. Numerous sites attributed to this race and still called Curumber Cotes, are to be met with. The number, site and condition of these with any remains still extant, should be carefully ascertained and noted. Small communities of the same tribe are found to this day in the less accessible hills and forests of many parts of the peninsula.

#### 2. The Cholas.

The several capitals of the Cholas were at Conjevean, Wori-ur, Combaconum, Gaugondaram, Tanjore. The whole history of this, the most important power in the Peninsula, is involved in great obscurity. We have no authentic information that can be trusted, anterior to the 9th century, yet they must have been exercising

sovereignty in the time of Ptolemy, who makes mention of "Arcati soren," and in the Mahawanso frequent references to transactions with the Cholas occur during the earliest periods of the Singhalese annals. The Tamil traditions abound with stories of Adondra Chakravarti, who appears to have been the subduer of the aboriginal or Curumber tribes before mentioned, yet no trustworthy records of his origin and actions are forthcoming, neither have authentic accounts of the overthrow and extinction of any of the great Southern States been yet obtained.

3. The Pandyan capitals were at Kurkhi, Kalyanapura, Kulasekara pattanam and Madura. The site of Kurkhi or Horkai is still a matter of dispute. It has been considered to be the Kolkhi of the Peripuls identified by D'Anville with Kilakarai near Ramesseram, and by others with Korkai or Gorkai near the mouth of the Tambraparni.

4. The Chera princes appear to have been established first at Seandapura in the Malabar Coast and subsequently at Talcaul or Dalavanpura on the Caveri and Mudugonda patnam, perhaps the same as the modern village of Mudugondoor on the road from Seringapatam to Koonghul. The locality of Seandapuram remains to be ascertained. Buchanan describes Talcaul as a place of some extent, containing many buildings nearly covered with sand. Beyond this cursory notice, no description of it appears to be extant. It is not even named in Hamilton's Gazetteer. The "*Carura* regio Cerebothri" has been supposed to indicate that Caroor in the Coimbatore country was one of their earliest seats.

The whole of the early history of these three last mentioned dynasties, their wars, alliances, intermarriages and conquests; their relations with Ceylon and with the Mahomedan colonies of Maabir and the Malabar Coast, (the founders of which approaching by sea obtained a footing in South India before the entry of their co-religionists from the North-West,) are involved in the greatest doubt and obscurity, which can only be elucidated by a careful examination of their remaining monuments. The traces of Southern Mahomedan establishments should also be carefully noted.

The Western Coast comprising the ancient kingdom of Kerala, some time subject to the Cheras, likewise offers an interesting field of research. The frequent mention of the principal places by the Greek and Arabian Geographers, the ready access afforded by its ports to maritime enterprise, the colonies of Persians, Arabs, Syrians, Jews, established there from the earliest times, may all receive important elucidation from an examination of existing remains of ancient sites. Although more subject to the operation of external influences than most other parts of India, it is here that the early Hindu institutions

have been best preserved, and that we may look with the best founded expectations of enlarging our knowledge of aboriginal races and primitive customs. The remarkable tribes to be met with in the depths of the forests and mountains of the Syhadri range, the traditions of the polity of Parasurama and of the arrival of some of the present dominant classes, the Haigas, Chitpawans, Namburis, Teers or "Islanders," &c. afford curious sources of inquiry and speculation.

In the addition of the above specified sites of political interest, the great religious institutions and establishments demand attention, such as Sri Sailam in Cuddapah, Canjeveram, Chellambaram, Srirangam &c. There are also many religious edifices of great architectural merit very worthy of being depicted and preserved for the beauty of their sculpture and elegance of their design, such as the stone mantapam in the Fort at Vellore now used as an Arsenal, the temples at Tanjore, Gangondaram and Tribhuwanam, the ruins of Bijanagar, the pagodas at Leepichi in Bellary, Tarpatri in Cuddapah, with many others equally worthy of admiration, in secluded and desert places, little known beyond their immediate neighbourhood, which would doubtless reward the institution of careful enquiries. Short descriptions of all such edifices should be particularized in the reports. It is worthy of remark that nearly all the finest buildings of early times have been constructed of stone, while the edifices of modern times, (that is within the 500 years), comprising some of the most stupendous piles at present to be met with, are of brick.

If the range of inquiry is extended to Hyderabad and Mysore, the list might be greatly extended. The Nizam's territories comprehend the seats of some of the greatest and most powerful sovereignties of the Dekhan. Such as Calyan the capital of the Western Chalukyas, and Bijala rayas; Devagiri or Deoghur the capital of the Yadavas; Warangal that of the Kakateyas; and the great Mahomedan principalities of Calburgah, subsequently split into the subordinate powers of Bijapur (the Adil Shahs) Ahmednagar (Nizam Shahs) of Golconda (Cutub Shahs) Berar (Imad Shahs) and of Beder (Birud Shahs) &c.

In Mysore we find the Bellalas, a Yadava dynasty reigning at Dwarasamudram the modern Halibidu.

The points on which information is more particularly desirable are

1. The existence of Cave Temples.
2. Sites of ruined and deserted cities or places of importance fallen to decay though still inhabited, particularly such as tradition states to have been capitals of former rulers.
3. Stone or other ancient pagodas of magnitude or fine architecture. Many of these are now deserted and in ruins. For examples we may in-

## ANDROPOGON ACICULATUS.

stance the great temples at Tanjore, Gangondram the brick structure at Negapatam supposed to be a Buddhist work &c. The brick remains of the palace of the Cholas near Combaconum.

4. All paleographic remains, such as sasamams and other ancient grants, whether stone or copper. Wherever a considerable number of the former occur in the same place, a hopeful field for investigation may be expected. The copper grants may easily be copied, if sent to the Presidency, and returned to the owners.

5. Sculptured rocks or walls, or stones, whether monumental or commemorative of important persons or events.

6. Ancient walls, fortifications, durgas or hill forts. Such as the wall said to make the boundary between the Chola and Pandya kingdoms in Madura, remains of which have been traced near Ramagiri, the Cuddanags of Coorg &c.

7. Remarkable mounds indicating sites of towns, fortresses, or other buildings, such as the tope at Dipaldinni on the Kistna, the mounds called Curumber Kotes, the Buddha Teppes or heaps of scoria described by Captain Newbold.

8. Fine works of utility or irrigation, such as the Tungabhadra and Caveri anicuts, the Poneri tank in Trichinopoly, the bridges at Sivasamudram and Anagundi, &c.—*Minute of Mr. Walter Elliot*.

(112) ANDROGRAPHIS PANICULATA. (Justicia Roxb).

Kalupnath or Mulla tita,	Kalamegh, HIND.
BENG.	Kreyat root, ENG.

In India the roots of this plant has long been a popular febrifuge and stomachic. It is the basis of the Drogue amere. It is the genuine or original chiretta.—*Ind. An. No. 6*.

(113) ANDROMEDA FASTIGIATA; the Himalayan heather, grows abundantly on Mon Lepcha, at 13,080 feet, and affords a good fuel.—*Hooker, Vol. I. p. 343*.

(114) ANDROPOGON. Species of this genus, to the number of eighteen, are given in Voigt's Catalogue of Calcutta plants, Andropogon arundinaceus, binatus, Baladhii, conjugatus, cymbarius, ~~glober~~, iwarancusa, Martini, mili-forinis, muricatus, nardus, pertusus, prostratus punctatus, Roxburghianus, scandens, Schoenanthus, trispicatus.

(115) ANDROPOGON ACICULATUS, NEEDLE LIKE ANDROPOGON. Spear grass.

Soorwulla, Soorwul, HIND. | Shunkinee, SANS.

In Ajmere abundant in barren land, troublesome to the feet of those who walk among it, eaten by cattle when other grass is not to be had. The common names of this variety are "lampa" and "chora-kanfa." A longer variety known solely as "soorwul" is an excellent grass for cattle.—*Genl. Med. Top. p. 176*.

## ANIME.

(116) ANDROPOGON BICOLOR. Black Joar,

Kala Joar, HIND.

Is cultivated in some places.—*Genl. Med. Top. p. 176*.

(117) ANDROPOGON NARDUS. LEMON GRASS.

Wassanapilloo, TAM.	Gendbel, HIND.
Naringe ke bas ka ghas,	Boostrina, SANS.
DRK.	

The Wassanapilloo makes a very pleasant tasted tea and valuable diet drink.—*Ainslie's Mat. Med. p. 258*.

(118) ANDROPOGON MURICATUS. Sharp-pointed Andropogon. Garrar, Gandar Hind. the plant; khuss-khuss Hind. the root.—*Genl. Med. Top. p. 176*.

(119) ANDROPOGON SERRATUS. Serrate Andropogon. Khura also Khurrar also Jeemoota, Hind. Grows in moist places in the plains, is considered the best grass at Ajmeer to preserve for cattle.—*Genl. Med. Top. p. 167*.

(120) ANEMONE. Speaking of these Mr. Fortune says, that many which he first imported have found their way to the principal gardens in Europe, and when writing in October, 20, 1846, the Anemone japonica was in full bloom in the garden of the Society at Chiswick, as luxuriant and beautiful as it ever grew on the graves of the Chinese, near the ramparts of Shanghai.—*Fortune's Wanderings, page 405*.

(121) ANGELIC TREE.

Angelic marum also Assanpela marum, TAM.

(122) ARTOCARPUS PUBESCENS. Willd. This grows in Travancore, and is commonly used, in that country, for ship building. The bark of the tree is employed, in Canara, in preparing a brownish dye.—*Ains. Mat. Med. p. 209*.

(123) ANCHUSA. Voigt names A. officinalis, paniculata and undulata, as having been grown near Calcutta.

(124) ANIMAL CHARCOAL, or Ivory Black. Carbo animal is; Dr. O'Shaughnessy tells us when pure, is entirely dissipated on talc or platinum, if burned with Nitrate of Ammonia. Should not effervesce on addition of Muriatic Acid, and the filtered liquid should give no precipitate on Ammonia being added.

(125) ANIMAL OILS. The following were exhibited at the Madras Exhibition of 1855.

Oil made of Peacock's fat from Tinnevely.
Neat's foot Oil.....from Masulipatam.
Alligator's fat .....from Do.
Guana Oil, Mr. Bowden from Guntoor.

(126) ANIME. As the mutual resemblance between Anime and Copal renders it often difficult to discriminate them, it may be useful to subjoin the following decisive test of distinction. Copal is nearly insoluble in alcohol; Anime is readily and totally soluble therein. Let a few grains be put in a wine glass with a little

## ARCHIPELAGO OF INDIA.

alcohol: if it be Anime, it will dissolve; if Copal, it will sustain no diminution.—*Comp. Descr.*

### (127) ANONA RETICULATA. Lin.

#### *The Fruit.*

Ramasita pullum, TAM.	Manna, MALAY.
Rasm sita pull, DUK	Bullocks Heart. ENG.
Rama sita pundo, TEL.	Rama sita, SANS.

This soft, sweetish, pulpy fruit, is not much sought after by Europeans who consider it as heavy and unpalatable.—*Ainslie, p. 232.*

### (128) ANONA SQUAMOSA. Lin.

Sita SANS.	Custard apple, ENG.
Sita pullum, TAM.	Seeree cayoo, SUMATRAN.
Sita pull, DUK.	Manna Papuwa, MALAY.
Autacheeka, MAL.	

This fruit is wholesome and nutritious, and being perfectly free from acid may be given to such delicate people, as dare not venture on others of a different nature.—*Ainslie, p. 232.*

### (129) ANTIDESMA ACIDA. Lin.

Poolchie pullum, TAM.

This acid fruit eaten by the common people, grows in the woods.—*Ainslie, p. 321.*

### (130) ANTIDESMA ALEXITERIA. Lin.

#### *The Bark.*

Noelha talie puttay, TAM.

From the nar or tough stringy fibres of this bark, the inhabitants of Travancore make ropes.

#### *The Fruit.*

Noelha Tali pullum, TAM. | Nuli Tali, HORT. MAL.

This is a pleasant tasted, reddish coloured fruit, said to be prized, on the Malabar coast for its cooling qualities.—*Ainslie, p. 183 & 229.*

(131) ANTIMONY. At the Madras Exhibition of 1857, Sulphuret of Antimony or Soorma of good quality was exhibited from Vizianagram. The substances sent as Soorma from Kurnool and Hyderabad were Galena or Sulphuret of Lead, and Dr. Scott intimated that he has frequently tested the Soormas of the Bazar and found that they do not contain Antimony but that they usually consist of Iron ore or Galena.

### (132) ARCHIPELAGO OF INDIA. EASTERN ARCHIPELAGO. INDIAN ARCHIPELAGO.

The following observations are from the pen of Mr. Earl. The contrast which the volcanic Islands of the Archipelago afford when compared with the continent of Australia is very strikingly presented to the view of a voyager from Port Essington, crossing for the first time the sea that separates the continents of Asia and Australia. Even before he has lost soundings on the great bank which extends from the northern shores of the latter continent, the lofty mountains

## ARCHIPELAGO OF INDIA.

the colour of the water suddenly changes from green to deep blue; he has now passed the steep edge of the bank, and is floating on the unfathomable seas which bounds the volcanic Islands of the Archipelago. On closer examination, he finds that the land of Timor rises abruptly from the depths of the ocean, so much so, that from many of the precipices which overhang the sea, a line of great length will not reach the bottom, while the very few spots on which anchorage is to be found are so close to the shore as to be available only when the wind blows from the land. And to complete the contrast, if the weather is clear we perceive that one of the mountains near the east end of Timor is an active volcano. The chain of Islands which extends from Java to Timor is of the same character; lofty volcanic peaks, some in a state of activity; while the Islands are separated from each other by narrow channels of unfathomable depth, through which the current from the Pacific, caused by the prevalence of easterly winds, rushes with great force; but on passing these the voyager again perceives a change in the colour of the sea from deep blue to green, and, on sounding, he finds a bottom of stiff clayey mud, resembling exactly that of the bank which fronts the northern coasts of Australia, he is now on the great bank which extends from the south-eastern extremity of Asia far into the seas of the Indian Archipelago. The Islands now lose their volcanic character, and on arriving at Singapore, near the extremity of the Malay Peninsula, the general resemblance of the country to that in the neighbourhood of Port Essington is sufficient to strike the most careless observer. The land low and undulating; the shore with red cliffs alternating with sandy beaches; even the rocks of the red iron-stone known to Indian geologists by the name of laterite, are perfectly in character with the country of the Coburg Peninsula, and even on closer examination little difference can be discovered except in the vegetation.

These banks of soundings which extend from the continents of Asia and Australia, form very remarkable features in the geography of this part of the world, and, as such, are deserving of more attention than has hitherto been bestowed upon them, since it will be found that all the countries lying upon these banks partake of the character of the continents to which they are attached; while those which are situated on the deep sea which separates them are all of comparatively recent volcanic formation, with the exception of a few small coral Islands, which in all probability, are constructed upon the summits of submerged volcanoes. Mr. Darwin's essay on the "Structure and Distribution of Coral reefs," has satisfactorily shewn that "Atolls"

## ARCHIPELAGO OF INDIA.

constructed around islands that have since subsided. The depth of water on these banks averages about 30 fathoms, depending rapidly as the edge is approached, and shoaling gradually towards the land. The one termed the *Great Asiatic Bank* extends into the Archipelago from the south-eastern extreme of Asia to a distance of nearly 1000 miles, in fact to within 50 miles of Celebes, and we may suspect that it will be found to extend to the south-western extremity of that Island also; but as there is a space of nearly 30 miles across which no soundings have been carried, the plan was preferred of reducing the bank to the limits for which we have actual data.

### *Countries lying on the Great Asiatic Bank.*—

The similarity that exists in the direction of the mountain ranges in the south-eastern part of Asia has often been the subject of remark. These invariably run in a direction nearly N. N. W. and S. S. E., and are all of the primary formation. The chain which extends along the Malay Peninsula is the most conspicuous of these ranges, and is continued at intervals to Banca and Billiton, and perhaps may be traced as far as the north coast of Java. It is this range that most abounds in metals, or, at all events, in which mining operations are pursued with greatest success, probably from the strata, owing to its central position, having been little disturbed by the convulsions which have shaken the countries on either hand. The productiveness of the gold mines of the Malay Peninsula and of the tin mines of Banca is well known. This range may be considered as the back bone of the *Great Asiatic Bank*. Sumatra, which lies on its western verge, has been subjected to volcanic action, but not to so great an extent as to disturb the direction of its mountain range, which runs parallel to that of the Malay Peninsula. The third and last range that can be traced into the Indian Archipelago is the one that traverses Laos and Cambaja, at the southern extremity of which it disappears for a time, showing itself only at Pulo Condor and Natunas, until it emerges near the north-west extreme of Borneo, and is continued along the entire west coast of that island. Here it again disappears, and only shows itself again on the north-coast of Java, where it ceases entirely; the remaining portion of this Island, with perhaps, a part of the north-west extremity, being either of volcanic formation or of alluvial deposit. It is rather singular that the celebrated teak-tree, which abounds on the Cambodian part of this range, but is not found in Borneo, is again met with here, the projecting part of the north side of Java, between Samarang and Surabaya, being a vast teak forest, from the timber of which the greater portion of the shipping employed in the Archipelago is constructed. Java is the only Island in the eastern seas in which

## ARCHIPELAGO OF INDIA.

the teak-tree is indigenous, nor will it thrive in the volcanic parts of the Island where its cultivation has been attempted. This, which we may call the *Cambodian Range*, is also rich in minerals, especially the Bornean part of it, where large quantities of gold and many diamonds are obtained by the miners. The volcanic Islands of the Archipelago also contain metals, gold-dust being found at the bottoms of many of the mountain streams, but it does not exist in veins, as in the Malayan Peninsula and on the west coast of Borneo, these having apparently been broken up by the violent convulsions to which these Islands have been subjected. The metal is therefore only obtained from the bottoms of the mountain streams, where it has been deposited when the earth in which it had been contained was washed away.

### *Volcanic Islands of the Indian Archipelago*—

The lines of volcanic action to which these Islands have been subjected can be traced with tolerable distinctness. One of these extends along the W. coast Sumatra and the S. coast of Java; whence it is continued by a chain of Islands, separated by narrow but deep channels, to New Guinea, and can be traced through that Island to the Louisiade Archipelago, and is probably continued by New Caledonia and Norfolk Island to New Zealand, thus forming a curved line resembling the letter S. The other line commences in Kamtschatka and extends through the Kurile Islands, Japan and Loochoo, to the Philippines, where it separates into two branches, one traversing Palawan and the N. W. part of Borneo, where it terminates near the limits of the *Great Asiatic Bank*, and the other continuing in a southerly direction until it comes in contact with the Sumatran line. It is near this point of contact that the volcanic action has been strongest, throwing the islands into fantastic forms, of which Celebes and Gillolo furnish striking examples. These islands all rise abruptly from an unfathomable sea, a circumstance unfavourable to their productiveness, since a large portion of the rich soil created by the decomposition of the volcanic rock is washed away into the ocean. Java, however, is in a great measure exempt from this disadvantage, owing to the *Great Asiatic Bank* extending to its northern coast, which prevents this soil from being lost, in lieu of which it is deposited in vast plains lying between the mountain range and the sea. These plains are so surpassingly rich that they not only yield a sufficiency of grain for the consumption of a large portion of the population of the Archipelago, but at the same time afford such abundance of sugar and other tropical produce as to furnish cargoes for many thousand tons of shipping.

*The Great Australian Bank.*—The remark

that has been made with regard to the ranges in the south-eastern part of Asia is equally applicable to Australia, since one of the most marked features in the geography of this continent is the uniformity that exists in the direction followed by all the continuous mountain ranges that have yet been discovered. The Darling range on the W. coast of Australia, the great chain that extends along the N. E. coast, with the range that traverses a portion of South Australia, and in which metallic ores have lately been found in such abundance, pursue a direction nearly N. N. W. and S. S. E.; and although the range on the E. coast of New South Wales vary somewhat upon this point, it is still to so slight a degree as not to require any particular remark. That this rule is also applicable to the lesser ranges is proved, at least as far as the shores are concerned, by all the deep inlets on the coasts of Australia preserving the same general direction, that is, running parallel to the mountain ranges; indeed so generally is this the case, that there is scarcely even a deep bay throughout the entire coast that does not conform to the general rule. The same occurs in Van Diemen's Land; indeed this Island must be considered as being a portion of Australia, for, although really insular, being surrounded by water, it is still joined to the continent by a bank of soundings on which there is a depth of from 35 to 40 fathoms.

The great bank which fronts the N. and N. W. coasts of Australia commences near the N. W. Cape, and extends in a N. E. direction to New Guinea, where it terminates at the base of the high but narrow mountain range that unites the eastern and western parts of that Island, and separates the Banda Sea from the Great Pacific. It is at this point that the edge of the bank is most remote from Australia, the distance to the nearest point of the N. coast being 400 miles. It appears again on the S. coast of New Guinea, near Torres Straits, and extends along the N. E. coast of Australia, the Great Barrier Reefs being on its outer edge.

The Arru Islands and New Guinea are thus united to the continent of Australia, and it is rather a singular coincidence that the kangaroo, an animal which was long supposed to be peculiar to Australia, is found both in the Arru Islands and on the southern part of New Guinea; as no specimens have been met with on the northern coasts of the latter Island by Forest and the French navigators who have been there, it seems to exist only on the portion included by the Great Australian Bank.

*New Guinea.*—The northern part of this Island, that is to say, the portion lying to the N. W. of the range of mountains already alluded to, partakes of the rugged and broken character of the volcanic Islands of the Indian Archi-

pelago, but the south-western part is low and undulating, and we may conclude that it bears considerable resemblance to the northern coasts of Australia, since the several Dutch navigators who explored the Gulf of Carpentaria, and who are in the habit of coasting this part of New Guinea on their way to Australia, considered them as being portions of the same continent, and they were thus delineated in our maps until Cook passed through Torres Strait and decided the question as to their insularity. A very interesting account of the S. W. coast of New Guinea, is given in Modera's "Narrative of the voyage of the Dutch Corvette 'Triton' in the year 1828," when this coast was explored with a view to forming a settlement: and contains information which bears upon this point.

*The Arru Islands.*—This group of Islands is situated on the northern verge of the Great Australian Bank, and extends from N. to S. about 100 miles; but as the eastern side of the group has not been explored, its limits in that direction are uncertain. Some of the southern islands are of considerable extent, but those to the N., lying close to the edge of the bank, are rarely more than 5 or 6 miles in circumference. The land is low, being only a few feet above the level of the sea, except in spots where patches of rock rise to the height of 20 feet, but the lofty trees which cover the face of the country give to it the appearance of being much more elevated. Coral reefs extend from the shores of all the islands, and in the eastern parts of the group these are often of great extent. The islands are divided from each other by narrow channels some of which are of great depth, and in one of these there is said to be a whirlpool of so formidable a description that the natives will not venture to approach it even in their larger vessels. I regret that during my recent visit to these islands my time was so much occupied by inquiries connected with the expedition to which I was attached, that I could not ascertain this fact from personal observation. Upon the whole, it is evident that this group has not been left quite untouched by the convulsion which has shaken its neighbours, a circumstance that might naturally be expected from its position on the very edge of the bank, and in the close vicinity of the volcanic chain, the Great Ki Island being only 60 miles distant.

When it is taken into consideration that the primary mountain ranges both in south-eastern Asia and in Australia, pursue a precisely similar direction, and that the westernmost Asiatic range, if continued, would strike about the N. W. Cape where the western Australian range commences, while banks extending from both these continents actually approach to, within 450 miles of each other, the question naturally

arises as to whether these continents were ever united. This inquiry, however, would lead to details of too extensive a nature to be admissible in a paper of this description, and which would belong rather to geology than geography, but it is well deserving of being followed up, since it possesses an interest beyond that which attaches to geographical matters generally; for if it be found that the mountain ranges of Australia are a continuation of those of eastern Asia, we may expect that they will also afford the mineral wealth for which the latter are so celebrated. Our colonies in Australia are now in a condition which would render the discovery of valuable minerals of the very highest importance. The amount of agricultural produce raised in these colonies is considerably above that required for the consumption of the inhabitants, who are now anxiously looking about the world for a market for their surplus produce, and such a market would be afforded by a population employed in mining operations. We may reasonably expect that mineral wealth is not confined to the district of South Australia. The great range extending the entire length of the N. E. coast is of a very promising description, as is also the range which abuts on the N. coast near the new settlement at Port Essington, and which, if it preserve the same direction which is observed in the other Australian ranges, may be connected with that of South Australia. The Liverpool, Adelaide, and Alligator rivers, the largest yet discovered in Australia, appear to have their sources in this range.

In conclusion, I will venture to suggest that the great banks alluded to in this part might be introduced into our maps of the Indian Archipelago with very good effect, and if delineated by means of the dotted lines, would rather improve their appearance than otherwise, while at the same time they would tend to illustrate to a certain degree the geological character of these countries. We have ample data from which to define their limits, except at the single point to which I have alluded in this paper, with regard to the S. W. extremity of Celebes.

The above was reprinted with the Journal Indian Archipelago from the "Transactions of the Royal Geographical Society" of London for the year 1845 (vol. XV. p. 358). The paper was submitted to the Society by the writer soon after his return to England from this part of the world in April 1845, and was intended as the first of a series of essays, suggesting points of geographical enquiry necessary to complete a system that would classify the productive character of the principal islands of the Indian Archipelago,—but circumstances rendered it advisable that the series should

be discontinued. Up to that period the narratives of travellers in the Indian Archipelago, although replete with valuable information, were generally deficient in those details necessary to complete a geographical system that would meet the requirements of the day;—indeed the extent and direction of the volcanic band which traverses the Archipelago, although studded with European settlements, was still undetermined; the active volcanoes supposed to exist near the northwest extreme of Borneo, and on Cape Island in Torres Strait, not having yet been erased from the maps by authority. But during the seven years that have since elapsed geographical research has progressed with such rapidity in this part of the world, that the general outline of its physical structure has been completed, although much remains to be done in the way of filling up the details. The surveying expeditions directed by the English government to those points where researches could be prosecuted without exciting the jealousy of other nations, have determined the character of Palawan, North-western Borneo, the eastern part of New Guinea and of the Louisiade group, while the scientific enquiries set on foot by the Netherlands Government with the view of developing the resources of its Eastern possessions have greatly enlarged our knowledge of the southern portion of the Archipelago. And, lastly, the Journal for which this essay is intended has been the means of bringing together, a mass of practicable information illustrating the geography of South Eastern Asia and the Indian Archipelago, as creditable to the collector as to the community which has supported his undertaking. In Australia, also, the progress of discovery has been so rapid and effectual, as to excite a feeling allied to astonishment, in those who have been accustomed to trace the slow but steady advance of the early explorers. This new impulse, which will soon leave nothing more to be done in the way of Australian inland discovery, was commenced by a traveller who possessed in an eminent degree that combination of courage and caution necessary to conduct a small party through regions occupied by wild tribes, together with a sound practical knowledge of all those branches of science to which the attention of travellers in unexplored countries should be directed. Alas! that I should have to speak in the past tense of a traveller whose career had scarcely been commenced, and whose generous devotion to the cause led him to undertake a journey calculated to decide at once all the remaining points necessary to complete a system of Australian geography. But the most sanguine have ceased to hope that even Leichhardt's dauntless spirit can have withstood the privations entailed by a protracted wandering in the wilderness.

But before entering again on the subject of physical geography, I find it necessary to state explicitly that the possibility of a connection having once existed between Asia and Australia, which I had advanced as the great incentive to further enquiry, was disputed at the general meeting of the Geographical Society before which it was read, by one of the leading members, whose high reputation as a proficient in the science of geology entitled his opinion to great weight. This opposition was founded on the conclusions arrived at by the celebrated comparative anatomist, Professor Owen, from an examination of remains of extinct Australian mammals, and which had been developed at the meeting of the British Association of the previous year. These conclusions had been adopted by some of the leading geologists, as will be seen by the following extract from the Presidential Address delivered at the Anniversary Meeting of the Royal Geographical Society which took place about the time.

The Transactions of the British Association, contain the admirable report of Professor Owen on the extinct mammals of Australia, and from evidence offered by his own Science, this great Comparative anatomist takes the broadest and soundest views of the connexion between the ancient and modern distribution of masses of land. Showing us that, as a whole, the extinct quadrupeds of our islands are closely analogous to those of the continents of Europe and Asia, and that these quarters of the globe are separated by no natural boundaries which could have caused great variation in the distribution of animal life. Professor Owen infers that England must have been a portion of the Continent, when it was tenanted with the same species of now extinct elephants, rhinoceroses, hippopotami, bisons, hyænas, tigers, bears, &c., inhabitants of the common Continent: even Africa is, on one of its flanks, so slightly divided from the rest of the old world of the geographer, that its existing races of mammals in some sort intermingle; though certain quadrupeds, as the giraffe and hippopotamus, which have become extinct in Europe and Asia, still exist in Africa. But when we cast our eyes to Australia on the one hand, or to South America on the other, then is the fauna as entirely dissimilar in each, as we should expect to find it in countries partitioned off by such wide seas and great natural barriers. From observing the fact, that the fossil mammalian remains of these two continents are as unlike those of Europe, Asia and Africa, as their present quadrupeds, Professor Owen rightly concludes "that the same forms were restricted to the same provinces at a former geological period, as they are at the present day;" and thus he sustains the views of modern geologists, that in those periods immediately anterior to our own, the geographical features of the earth must have been the same as those which now prevail.

*Address to the Anniversary Meeting of the Royal Geographical Society, 26th May 1845, by Sir Roderick Impey Murchison, V. P. R. S. L. G. S., &c. Sec., President, p. 75.*

An examination of specimens of Australian fossil Flora brought to England by Count Strzelecki in 1844 and which had been submitted to Mr. J. Morris for comparison, presented very different results, as appeared in the following extract from his report:

"In instituting a comparison between the species collected from the Australian deposits, and those described from the Burdwan coal-fields by Professor Royle, we observe both the remarkable analogy of form of some species, and the actual identity of others; from which we may probably be led to infer that the deposition of the strata containing them was not only contemporaneous, but that the conditions of the flora of some portions of the Indian and Australian Continents, at that epoch, were not very dissimilar."—Strzelecki's Physical Description of New South Wales, p. 253.

The recent discovery of fossils of well known "Silurian" species in the mountain ranges of New South Wales, has further established the fact that Australia is not an outcast from the family of continents, notwithstanding Blumenbach's famous theory. It is true that the fossil remains of mammals discovered in the limestone caverns of the Wellington range and the Kanobolus are all of the marsupial character, but this merely proves that if mammals of the forms now existing in Europe and Asia ever inhabited Australia previous to their introduction by man (which is by no means probable) they deposited their bones elsewhere.

But to return to the subject under review. The great desideratum of 1845 was a more perfect knowledge respecting the arrangement and distribution of those tracts of land which shewed distinct proof of disturbance by volcanic action, yet retained in some degree the characteristics of primary formations. I had an opportunity of inspecting the eastern extremity of one of these tracts in 1832 when on the south coast of Java. It is thus described in Dr. Horsfield's "Mineralogical Sketch of the Island of Java," which is inserted in the general map of that island by Sir Stamford Raffles, in his "History of Java." "Extensive district of secondary volcanoes mixed with hills of Limestone, especially near the sea, where the Limestone rocks are piled up to great heights—basals Basalt and Wackem, Breccia in the beds of rivers;—also Porphyry, Jasper, Cornelian, Agate, Obsidian. In some places Quartz appearing in Rock-crystals, Prase or Amethyst, rarely siliceous petrefac-

## ARCHIPELAGO OF INDIA.

opportunity of inspecting one of the larger and less dependent areas of this formation, on the occasion of a journey across Moa, one of the lands lying immediately to the east of Timor, which appeared to consist of a mass of land, upheaved to its present elevation without any further disturbance of the strata, than was just sufficient to show that the remains of marine animals of forms corresponding with those still existing in the neighbouring waters, which are scattered pretty plentifully over this island, owed their presence rather to the upheaval of the land, than to the retreat of the waters which must once have covered a portion of its surface. But it is on the neighbouring Island of Timor, where the line of subterranean action has crossed primary ranges, that the evidence of this simple upheaval is most striking and distinct. There masses of land of purely primary formation, with the animal and vegetable kingdoms closely corresponding with those of the neighbouring continent of Australia, are found lying on tracts sprinkled with corals and marine shells, some hundreds (indeed I may safely say, thousands) of feet above the present level of the ocean. That these tracts owe their elevation to upheaval, may be inferred from the circumstance of the process being still active, a fact that can be ascertained without much investigation at the principal European ports, Dilli and Copang ;—in the former by comparing the present elevation of the reef of coral which forms the harbour, with the accounts given in the old Directories, and in the latter by inspecting the madreporic cliff on the brow of which part of the town is erected.

These "Areas of Upheaval" as I have been induced to name them, include at least as large a portion of territory in the Indian Archipelago as that occupied by the active Volcanic Bands, in which nearly all traces of former character is lost in the chaos that has been produced by the intensity of the volcanic heat. The leading characteristics of the "Areas of Upheaval" consist in the general distribution of limestone formations, often in the form of the "mountain limestone" of England,—in the presence of pretruded minerals in those spots where the line of upheaval has crossed primary ranges, and the subterranean heat has been sufficiently great to project the metals ;—and in the prevalence of upraised coal beds where the subterranean force has been so slight as to be exhibited only in upheaval, without great disturbance of the strata.

*Primary Ranges.*—With a view to simplicity of arrangement, I include under this term all formations antecedent to the recent volcanic epoch, adopting as a test the presence of primitive granite in situ. During the last few years, much additional information has been obtained respecting the ranges of South Eastern Asia.

## ARCHIPELAGO OF INDIA.

Of the Malayan Range, the limits are pretty accurately defined by the coast lines of the Peninsula. Some valuable information has been obtained respecting the range which runs along the western coast of the Indo Chinese Peninsula, dividing the ancient Kingdoms of Cambodia and Laos from that of Siam. See Journal of the Indian Archipelago vol. v. p. 306. This range ceases as a continued chain at Kampot in Lat.  $11^{\circ}$  S. but is continued by isolated hills and ranges to the south extreme of the Peninsula. No addition has been made to our knowledge of the Anam or Cochin-Chinese range, beyond a confirmation of the fact that it runs parallel to the east coast of the Peninsula throughout its length.

In my essay of 1845, he remarks, I have continued the Cambodian Range from the northwest extreme of Borneo to Gunung Ratos, near Banjar Massin, an error into which I was led from it being the only primary range on the coast of Borneo with whose extent I was then acquainted. I must have fallen into this error from information received during my visit to Borneo in 1834, as I find these ranges thus alluded to in a paper on the Geography of Borneo which I drew up at the request of the late Sir Alexander Johnston in 1837, and which is published in the Transactions of the Royal Asiatic Society for that year.

"One of the Eastern Asiatic ranges, after extending along the S. W. coast of Sumatra, terminates at its S. E. point. Another runs along the Malay Peninsula, is lost for a time, but appears again in the high peak of Lingin, and terminates in Banca and Billiton, and a branch from this separates at Pulo Timoan, on the east coast of the Peninsula, and ends at Carimata, in the strait between Billiton and Borneo. Two ranges traverse Cambodia and Cochin-China in the same direction, and these will be found to extend to, and, perhaps, to traverse Borneo. Between the Cambodian range and the mountains at Sarawak, on the northwest extremity of Borneo, the Natunas islands and Pulo Condor form the connecting link ; and as the Sarawak hills run to the south-east, the range is probably continued, either by a connected line, or by isolated mounts, until it terminates in the Gunung Ratos, near Cape Selatan." More recent data shew that this range, after traversing the western part of Borneo, terminates on the south coast, a little to the eastward of Kotaringin. The Gunung Ratos would therefore appear to have been formerly connected with the primary range which shews at Bintulu, on the northwest coast of Borneo, and which may be a continuation of one of the Indo Chinese ranges. The Anam or Cochin-Chinese Range is that which can be traced most distinctly across the Archipelago to Australia at the present day.

The interval between Cochin-China and Borneo will appear great, unless we consider the reefs and shoals which extend across this part of the China Sea, to be submerged links of the chain. When once across this submerged area, the primary ranges of Cape Kaneungan and the southern limbs of Celebes continue with little interruption to a point only 240 miles distant from the outer verge of the Australian Bank of Soundings, and no great stretch of the imagination is required to carry it on to the upheaved remains of primary formation in Timor, and thence to the Arnhem Peninsula in Australia.

The *Sumatran chain* must be dismissed from the list of primary ranges; for although it evidently has been of this formation, and was probably connected with the continent of Asia by a line passing through the Nicobars and Andamans, yet the strata have been so disturbed by the volcanic band which extends along the western coast, that no portion of the old formation has been detected in situ. An area of upheaval seems to extend along the centre of the island from one extremity to the other, but the great breadth of the alluvial plains which form the eastern coast, from Diamond Point to the Strait of Sunda, has hitherto prevented a close inspection except in two or three spots. If the laws which regulate the deposition of the substances from which coal is formed, and the upheaval of the beds into positions available for the use of man, are the same here as in Australia, the inland parts of Sumatra opposite this settlement are likely to contain coal beds at least as extensive as those of New South Wales, but the width of the alluvial plains lying at the base of the area of upheaval will render them more difficult to discover, as the cliffs in which the coal crops out on the east coast of Australia rise abruptly from the sea-shore, and the beds can be detected from boats passing close along the land.

In the Philippine Islands, Mindanao, the Gilolo Group, and in the western peninsula of New Guinea, distinct traces of the former existence of primary formations are shewn by the presence of the descriptions of minerals which are less liable to destruction by intense volcanic heat. But as far as my experience goes, no particle of this formation in its primitive state has been detected throughout the groups which form the eastern barrier of the Archipelago.

In Australia the most important modern discovery connected with physical geography, was made by Dr. Leichhardt during his memorable overland journey from Moreton Bay to Port Essington in 1845, during which he established the connection between the Monobar Range which abuts on the north coast near the Cobourg Peninsula, and the great eastern coast range, from which it appears to branch off about the

parallel of the tropic. Leichhardt only traced the range across the Arnhem Peninsula, and along the southwestern side of the Gulf of Carpentaria, a distance of about 600 miles, but its continuation in the same direction can scarcely be considered problematical, as at the furthest point reached by Sir Thomas Mitchell in the following year (about Lat. 24° Long. 145°) the country dipped to the southward towards the stony desert discovered by Captain Sturt during the previous year (1845) near the northern boundary of the South Australian colony. In my former essay, he continues, I anticipated that the Monobar Range would be continued to the neighbourhood of Spencer Gulf, but if a branch had extended in this direction, Captain Sturt, must have met with it during his late perilous journey in the interior. The direction taken by the South Australian ranges is still undetermined, although it can scarcely be considered doubtful. This, the only remaining point necessary to complete our acquaintance with the general physical structure of Australia, would have been decided had Dr. Leichhardt survived to complete his last journey. At present, the honor of being the first to trace the course of this central range appears likely to fall upon the enterprising colonists of South Australia, who have already pushed their exploration from the west side of Spencer Gulf along the range to the northwest, and the result is calculated to encourage them in the further prosecution of their enterprize.

The primary ranges rarely attain a very great elevation, about 6,000 feet being the highest point. In this particular they are far inferior to the volcanic and upheaved ranges, but this deficiency is amply compensated by their excessive width, indeed each range seems to consist of a number of small parallel ranges overlying primary bases sometimes as much as 300 miles, and rarely less than 100 miles, in breadth. The higher points are generally massive and rounded, although peaked mounts are not uncommon, especially in the neighbourhood of the volcanic bands. The only known table-lands of large extent are those of Laos or Upper Cambodia, and the plains discovered by Sir Thomas Mitchell in 1846 near the northern boundary of New South Wales. The latter are 2000 feet above the level of the sea.

*Productive Character.*—The primary ranges in South-eastern Asia and the Indian Archipelago are all more or less metalliferous, but the labour of working under ground, and extracting the metals from the matrix, is so unsuited to the habits of the natives, that mining operations are only carried on in those countries which are subjected to despotic governments. Lead mines are worked in that part of the Malayan Range which traverses the kingdom of Ava; and copper-

mines have been opened in the Anam or Cochin Chinese range, the produce of which is equal in quality to South American copper, but inferior to that of Japan. The produce of these mines has been imported into Singapore, that of Anam in considerable quantities, but the cessation of commercial intercourse has put a stop to the importation. Iron is also smelted from the native ores on the western side of the Anam range, and it is said that silver mines are also worked, but I cannot vouch for the correctness of the report. Elsewhere in this region, mining operations are confined to the collection of metals that have been projected from the original site by subterranean heat, which can be traced distinctly to recent volcanic action. The tin of the Malay Peninsula, Banka, and Billiton, and the gold of the Peninsula, Borneo and Celebes, are all collected from the detritus in which the projected metal has been deposited. Lead and antimony ores are found in the Cambodian Range to the north of Kampot, but no mines have been opened.

In Australia, the southern portions only of the primary ranges have been attentively examined, but as far as the search has been extended, it would go to prove that the primary formations of this continent are equally metalliferous with those of South Eastern Asia. Copper ores have been found at Port Curtis, near the southern extremity of the range which extends along the northeast coast, and as long ago as 1802. Flinders met with indications of copper at Goods Island in Torres Strait; but his suggestion does not seem to have been followed up by the naturalists attached to subsequent expeditions. The stone is granitic and brittle; but there is also porphyry, and in one place I found streaks of verdigris, as if the cliffs above had contained copper ore." (Flinders' Voyage to Terra Australis, vol. II. p. 120.) Lead and copper mines have been worked in South Australia for some years past, and others have been opened recently in the western coast range, a little to the north of Swan River. The massive range, which extends from Cape Lieuwin to Cape Naturalists does not appear to have yet been explored, but from a cursory examination of its southern extremity during a residence in the neighbourhood in 1831, I was led to suspect that this southwestern peninsula might some day become the Cornwall of Australia. Hematitic and specular iron ore and copper pyrites, have been found on the northwest coast near Admiralty Gulf, which may be considered sufficient to establish the metalliferous character of the northern part of the Central Ranges.

The productive character of the surface soil of this formation, which consists chiefly of decomposed sandstone and crystalline rock, is inferior to that of both the other areas, indeed it is only in the great river basins, which are favourably

situated for irrigation, that agricultural produce is raised in sufficient quantities to allow a surplus for exportation. But on the other hand the superior quality of the forest timber which overspreads this area is daily becoming more appreciated, and probably many valuable gums and guttas still remain to be discovered. In Australia, the prevailing vegetation differs materially in its character from that of south-eastern Asia, the forms now existing throughout the interior of Australia being identical with those discovered in the coal beds of New South Wales, and, it would seem, in those of Upper India also. The process by which the existing forms of Indian vegetation have been introduced, may be traced in the following extract from a little work describing the Cobourg Peninsula Port Essington, which was published by the writer when last in England:—

"Throughout the Cobourg Peninsula, generally near the sea-shore, are found patches of land varying in extent from two or three acres to fifty acres and upwards, on which the vegetation is perfectly in character with that of the Islands of the Indian Archipelago. These spots are covered with a thick jungle, difficult to penetrate, and the trees are often of an enormous size. Among these I have recognized the waringin, or banyan-tree of Indian Islands; the kanuri, (a tree producing a nut which yields a kind of a sweet-oil, and under the shade of which the nutmeg trees are planted at Banda,) together with many others common to the Spice Islands. The shrubs, and even the birds that inhabit these patches, are also in character with those of the Indian Islands; the kangaroo which seeks shelter here from its enemy, the native dog, being almost the only peculiarly Australian animal that is found in them and these obtain their food in the open grounds.

"The plants obtained from the countries of the Archipelago that are of the primary formation, invariably flourished better than those from the volcanic islands; the productions of Singapore and of the Malayan Peninsula adapting themselves at once to their new quarters. This is accounted for by the circumstance of the soil, and even the rocks and stones of the Northern coasts of Australia being precisely similar in their character to those of the countries in the south-eastern parts of Asia. Even the general direction taken by the hill ranges is the same in both countries, and were it not that they are separated by a narrow but unfathomable gorge, studded with volcanic islands, they might be considered as forming portions of the same region. The indigenous productions of the soil certainly differ considerably in their character, but a process is at present going on in Australia which, in the course of time, if left untouched, would produce a similarity upon this point.

## ARCHIPELAGO OF INDIA.

Innumerable patches of oriental vegetation, many of them thousands of acres in extent, are spreading inland from the northern and eastern coasts, even in spots far beyond the tropics, eating up, as it were, the Australian vegetation, which disappears before them as the marsupials disappear before the animals of Europe. Every inch of ground gaisted is made good. The dense foliage, impervious to the sun's rays, spreads out above, sheltering the mass of dark vegetation that accumulates on the surface of the ground, which is thus left to rot and form new soil."—*Enterprise in Tropical Australia* pp. 76 and 106.

The leading feature of an Australian landscape consists in the open nature of the forest, which proves highly favourable to pastoral pursuits. Owing to the comparative poverty of the soil, the growth of the forest trees is slow, producing that durability in the timber for which the English oak is so esteemed, but in a much greater degree, the wood of several of the prevailing forms of the Eucalyptus being apparently indestructible except by fire, and then it burns with slowness, throwing out a heat scarcely inferior to that produced from coal: indeed the common gum wood, burning in the gally range of a frigate, when the flame ceases, can scarcely be distinguished from a glowing sea-coal fire. Stumps of trees cut down in the neighbourhood of Sydney in 1788 were still standing in 1847 without any other appearance of decay than the destruction of the bark, and will probably, if undisturbed, continue in the same state for a century to come. But the chief value of this timber consists in several varieties being obnoxious to the teredo or worm which perforates and destroys submerged timber, and proves so destructive to ships bottoms and wooden piles, especially in these tropical regions. The piles that were driven in 1838 to form the jetty at Port Essington, were perfectly sound when the settlement was abandoned ten years afterwards, while foreign timber that was allowed to remain in the water alongside the pier only for a few days, was invariably attacked by the teredo.

Up to a very recent period the submerged banks which extend from Asia and Australia furnished the principal articles of commerce supplied by the primary region. Agaragar, a marine lichen extensively used in China, trepang or sea slug, and mother of pearl shell, are common to both banks, but the Australian bank is by far the most productive, probably from its not having yet been so extensively worked as the Asiatic bank.

*III. Volcanic Bands.*—The limits of the volcanic band which crosses the Archipelago are so distinctly defined by the active volcanoes with which it is studded, that no difficulty is experienced in tracing its course. The few facts that our limited knowledge of the laws

## ARCHIPELAGO OF INDIA.

which regulate volcanic currents have enabled me to collect, lead to the inference that the volcanic stream originally commenced in the neighbourhood of Kamtschatka from which it takes a southwest direction through the Kurile Islands, Japan, and Loo Choo, skirting the Coast of Asia, to Formosa, where it abruptly turns to the south and southwest through the Philippines and Mindanao to the Moluccas, embracing the eastern extreme of Celebes and the western Peninsula of New Guinea, and then curves to the westward along the Tran Javan Chain to the Strait of Sunda, when it assumes a northwesterly direction through Sumatra and the Andamans to Cheduba island, in the northern part of the Bay of Bengal. It is not without a certain degree of hesitation that I have continued the band from the western extreme of New Guinea along the north coast of that island to New Britain, although its volcanic character has been decided by recent French navigators, for there remains a tract including thirteen degrees of longitude in which no active volcano has been seen. Indeed it is by no means improbable that the band which takes a southerly direction from Japan through Fatzima, the Bonin and Mariana Islands, may prove to be continued to New Ireland; in which case the chain of active volcanoes which extends through the Solomon Islands and the New Hebrides to New Zealand, and perhaps further to the south, may indicate the course of an independent stream.

It is to be regretted that no series of observations has yet been made on the periods of volcanic activity in different parts of the bands, as a mere daily record kept at the European settlements which are scattered along them, from Kamtschatka to New Zealand, and from the Moluccas to Bengal, during only a single year, would furnish data from which important points could be decided, that can now be only matters of conjecture. Indeed there can be no objection to such a simple and inexpensive series of observations being carried out throughout the world. The lines of volcanic action which have all but separated Europe and Asia from Africa, and the northern from the southern continent of America, have evidently been ruled by the same law with that which has effected the separation of eastern Asia from Australia; and the question must soon be boldly entertained whether the circulation of volcanic electricity is not as necessary to maintain the productive character of the globe, as that of the blood to preserve vital existence in the human body. But it is in the Indian Archipelago, where the process by which volcanic regions have been formed is still actively progressing, and where the smooth seas afford easy access to all the chief points of interest, that the greatest facilities are afforded for prosecuting the

## ARCHIPELAGO OF INDIA.

researches necessary to establish the basis of a system.

In these regions, so great has been the intensity of the subterranean heat, that where the volcanic bands have crossed or passed along ranges of the primary formation, scarcely a vestige of their former character remains, the primitive rocks being metamorphosed, and even the metals they contained melted up and dissipated; with the single exception of the most indestructible of all metallic substances, gold; the presence of which in minute grains, deposited in the beds of mountain streams, being, he says, as far as I have been able to discover, the only evidence that now remains to point out the former existence of primary ranges.

The process by which the volcanic formations have been thrown up, and by which large tracts of land in which the subterranean action has not broken through the surface have been raised to their present level, seems invariably to have been attended by a corresponding subsidence of the surface in their immediate neighbourhood;—indeed the facts brought forward by Mr. Darwin, in his essay on the “Structure and Distribution of Coral Reefs” go to prove that this subsidence still continues in those parts which are not affected by active subterranean force. The banks of soundings which extend from Asia and Australia present features which must class them as “Areas of Subsidence”; with the exception of certain spots which have been penetrated by lines of upheaval, and where the fringing reefs distinctly point out the character of the rocks and islets. Beyond the limits of these “Banks of Soundings” the sea is everywhere unfathomable a mile or two from the shore, indeed in many spots, no soundings can be obtained with an ordinary deep sea lead line from the brow of the limestone cliffs which often bound the shores of areas of upheaval. Even where the banks of soundings have been penetrated by areas of upheaval the depth of water is greater than elsewhere, and the shores, instead of sloping gradually into the sea, fall at once to depths corresponding with those of the bank generally. This is particularly apparent on the north-west coast of Borneo, in the neighbourhood of Bawian and Salombo, and on the western side of the Gulf or Carpentaria.

**Productions**—The productive character of the volcanic area is totally distinct from that of the primary formations. With the exception of gold, which is found scattered in minute particles in the beds of the mountain streams, no single production of the primary areas repays the labour of collection. This deficiency is amply compensated by the surpassing richness of the soil produced from the volcanic rock, which decomposes rapidly before the influence of the atmosphere. The natural productions are un-

## ARCHIPELAGO OF INDIA.

important, the nutmeg, which is scattered over that portion of the band which approaches the continent of Australia, being almost the sole exception. But the docility of the native inhabitants proved to be such that they were easily coerced to labour, and the curved volcanic band which traverses the Archipelago became studded with European settlements throughout its length and breadth, which now yield the great bulk of the produce exported from the Indian Archipelago. In the northern part of the Philippines, the famed Manila tobacco is the chief production; sugar plantations, which supply the Australian colonies, occupy the centre; and the *musa textilis* which yields the Manila Hemp is the chief product of the south. Spices are almost the sole production of the Dutch settlements of the Moluccas, inferior articles being neglected, as is the case in countries which produce gold. Some islands east of Java are still independent of European control, and these yield productions suited to the wants of the natives to such an extent as to give rise to an export trade with all parts of the Archipelago. In Java, coffee, sugar, rice, and tobacco, are the most important articles, the two first being exported to Holland in immense quantities. Coffee and pepper are the chief products of Sumatra, where the soil is less fertile than in some of the other islands of the band. The volcanic agency here becomes comparatively weak, and is confined to the outer coast of the island; where, being backed by an area of upheaval, the greater portion of the alluvium descends into the sea and is lost. I have not, he says, sufficient data to enable me to define the area of upheaval which intervenes the volcanic band and the north-eastern coast from the neighbourhood of Palembang northward, but its existence is distinctly shewn in the detritus brought down by the rivers. It is probably owing to this circumstance that the alluvial plains of Sumatra which abut on the Great Asiatic Bank are less fertile than those of Java, where the alluvium almost exclusively consists of decomposed volcanic rock.

**IV. Areas of Upheaval.**—Under this head are included all those masses of land which furnish evidence of having been raised to their present level by subterranean action, but in which the volcanic heat has either never found vent in the surface, or has subsided at periods anterior to the present epoch. These areas may be subdivided into two classes;—the first consisting of spurs extending from the western side of the volcanic band which bounds the Archipelago to the eastward; the other consisting of masses of upheaval land lying parallel and adjacent to the volcanic band. The first subdivision displays crystalline, igneous and aqueous rocks, upraised occasionally to immense elevations, with every degree of disturbance.

## ARCHIPELAGO OF INDIA.

from mere dislocation of the strata, to a state of chaos scarcely inferior to that of the volcanic areas. In fact these spurs furnish intrinsic evidence of having once been traversed by volcanic streams whose activity has ceased, probably at the period in which the stream finally succeeding in breaking across the primary ranges at a point where they offered least resistance. The prevalence of limestone formations, often exhibiting fossil remains of still existing species of marine animals, is the leading feature both of the larger and smaller areas, indeed the latter only differ from the others in being immediately dependent on the volcanic band.

Commencing to the north, the first area of upheaval can be traced from the neighbourhood of Manila in the Philippines through Mindora, Palawan, and along the northwestern part of Borneo, where the subterranean force has penetrated and piled up the primary ranges, but appears to have been stopped by the westernmost range, which, although disturbed, has not been broken through. The absence of any other visible cause, leads me to attribute the extraordinary projection of metal into the surface soil at the western base of the range, to the agency of this once active volcanic stream, but it is only recently that I have been able thus to account for the phenomena which I met with when inspecting the gold mines of Montradok in 1834. "The Eastern Seas &c. p. 281 et seq." This rule will be found equally applicable to the gold deposits of the Malayan Peninsula, Sumatra, Celebes, Timor, and New South Wales, the deposits being only found on the side of the range opposite to that against which the volcanic force has been directed.

A second area extends from Mindanao through the Sulu chain to the northeast extreme of Borneo, but its further progress cannot be traced until we are better acquainted with the geography of the interior of that island. A third line extends from the north-east extreme of Celebes, where the Klobat Mountain is still an active volcano through the northern peninsula of that island, and small areas of upheaval, with a corresponding subsidence of the adjacent surface, can be traced through the Lifle Paternosters, Pulo Laut, and Salombo, to Bawian. The subterranean force which has elevated Madura, and the chain of islands extending from it to the eastward, may have come from the north, but as the volcanic land passes in the immediate neighbourhood, it will not be safe to include these islands in an independent area of upheaval, until geological investigation shall have shewn their character to correspond with that of other parts of the area.

The eastern peninsula of Celebes, the Xulla Isles, Buru, Ceram and Mysol, all belong to this system, and I should be inclined to trace

## ARCHIPELAGO OF INDIA.

the line of upheaval from the neighbourhood of New Guinea, but some confusion exists hereabouts which cannot be cleared up without further enquiries. In all the recent physical maps that I have had access to, an active volcano is laid down as existing in the north-west part of Amboyna. As no mention is made by Valentyn or other old writers of an active volcano in this neighbourhood, I was not very minute in my enquiries when there in 1842, being satisfied that the southern peninsula possessed, in an eminent degree, all the characteristics of upheaval without great disturbance of the surface;—the limestone formations, especially, being apparently in the same relative position as when first formed.

But as this volcano must have been placed there on authority, I am not inclined to pronounce against its existence, especially as the range in the eastern part of Celebes is deflected to the south, or at right angles to the course of simple upheaval in that vicinity. In this case a volcanic band must be introduced as passing south from Gilolo through Ceram and Amboyna to the isolated volcano distant 180 miles to the S. S. W. of the latter Island. Should this prove to be the fact, a volcanic band will either have crossed an area of upheaval or must have thrown out lines of upheaval simultaneously to the right and left, phenomena which do not appear in other parts of the Archipelago.

The fourth area of upheaval extends from the southern part of the western peninsula of New Guinea through the Keli Islands, Timor Laut, the Serwathy Islands, and Timor, to Sumba, or Sandalwood Island. A recent volcanic band skirts the northwestern part of this area rather closely, Serua, Nila, and Damma having been active volcanoes since the arrival of Europeans in the Archipelago, but they are now either extinct, or very rarely in a state of activity. In my essay of 1845 I have pronounced the peaked mountain at the north-east extreme of Timor to be in a state of activity, having been induced to do so by the reports of natives of the adjacent island Kissa, and from my having on two several occasions seen the summit of the mountain in a state of ignition, but I have since been informed by gentlemen connected with the Portuguese settlements in Timor, that there are no active volcanoes in the eastern part of the Island. I must there have been deceived by the burnings of the jungle which the natives make towards the close of the year, for the purpose of clearing new lands for cultivation.

The eastern Islands of the Arru Group have been upheaved to the height of from 80 to 150 feet, a fact I was not made acquainted with till recently, although I had detected evidence of disturbance when visiting the half drowned western Islands of the group. As the animal and veg-

table kingdoms still correspond very closely with those of Australia, these Islands afford a clue to the former condition of the area now occupied by the great Australian Bank. So long ago as 1837, the writer endeavoured to draw attention to the Arru Group in a paper detailing the few important facts that were known concerning it, which was read at a meeting of the Geographical Society; but with the exception of a flying visit to the western part by Commodore D'Urville in 1839, when on his way from Port Essington to Torres Strait, and an equally hasty exploration we made in H. M. S. *Britomart* in 1842, nothing has been done towards extending our geographical knowledge of this group. The Dutch scientific expedition of 1827, which has contributed so much towards dissipating the cloud of mystery that hangs over these eastern islands, passed near the group on more than one occasion without calling; but it is to be hoped that the spirit of enquiry which is now predominant in Netherlands India, will not allow this small but interesting portion of its territory to remain a terra incognita.

The area next in rotation is that which extends along the centre of the greater or eastern Peninsula of New Guinea, at least. I have been induced to class this great mountain range as an area of upheaval. The western part of the range, which terminates at Cape Buro on the S. W. coast, has been known for nearly three centuries, and is named in the old Dutch Charts "*Sneeuw Bergen*" or the Snowy Mountains, owing to the upper portion of the range, as seen from the coast, appearing from its dazzling whiteness, especially when the sun is near the horizon, to be covered with perpetual snow. The altitude of this part of the range, as estimated by the officers of the Dutch corvette "*Triton*" in 1828, is only exceeded in this part of the world by that of the Himalaya. The eastern part of the range has lately been seen by Captains Blackwood and Stanley, and was found to consist of very high land, but scarcely attaining half the elevation assigned to the western portion. Captain Stanley did not survive to reach England, or he would probably have furnished some interesting details respecting this region. From the published narrative of his voyage, it would appear that the S. E. extreme of New Guinea, beyond the parallel of 9° S. is of primary formation. The central mass of mountain land has evidently been the result of upheaval, but whether the volcanic force is still active can only be decided when the range comes to be closely examined. I have therefore coloured this part yellow, as indicating simple upheaval.

Traces of upheaval are shown on the western coast of the Gulf of Carpentaria, by the notes of Captain Flinders in his "*Voyage to Terra Australis*," and by the description of the specimens

given by Dr. Fitten in his essay on the geology of Australia which is appended to Captain King's Narrative;—and evidence of the same nature was detected by Dr. Leichhardt in the interior of the Arnhem Peninsula, when crossing the line of action indicated by the direction of the ranges in the North-western horn of the Gulf of Carpentaria. Mountain limestone is also wanting to complete the resemblance of this area to that which extends from the south part of the Western Peninsula of New Guinea, named above the "*Timorian Area*." The essay of Dr. Fitton above alluded to, was read before the Geological Society of London in 1825. It is entitled "*an account of some Geological Specimens &c.*" but it is, in fact, a collection of all the geological data connected with Australia then extant, arranged and commented upon in a manner so eminently suggestive of points of enquiry, that the name of the author must be recorded as "*Father*" of the science of Physical Geography in Australia. Dr. Fitton's attention was particularly directed to the striking uniformity of arrangement that had been observed by Captain Flinders in the hill-ranges and chains of islands forming the northwest horn of the Gulf of Carpentaria, and their parallelism to the great range of Timor is distinctly noticed. Nor did he fail to call attention to the singular flat-topped hills which present so striking a feature on the northern coasts of Australia, and which had not yet been examined about the upper parts. Two of the most remarkable of these hills are situated on the Cobourg Peninsula, and were repeatedly examined by parties attached to the garrison of Port Essington. Dr. Fitton's anticipation of their importance as illustrative of physical geography, proved to be well founded; but as a description is not necessary to elucidate the particular subject now under review, I prefer making the "*Flat-topped Hills*" the subject of a separate essay.

The sixth and last area of the first class is found in the South-eastern part of Australia and in the eastern part of Van Diemen's Land. This area has been examined by one of the most practised observers of the day, the Count P. De Strzelecki, during a course of exploration extending over a period of five years, commencing in 1839, and the leading features of these important districts will be found fully described in his "*Physical Description of New South Wales and Van Diemen's Land*. London, 1845.—From a report of the proceedings of the Geological Society in the London Athenæum of February the 21st of this year, I perceive that two distinguished Geologists have brought their rival claims to the honor of having anticipated the discovery of gold in Australia, before that Society. A mere cursory perusal of Count Strzelecki's publication will be sufficient

to shew, that by proving the physical features of the Sydney mountain range to be identical with those of the Russian Ural, the great gold field of the day, he pronounced in language that could not be mistaken by the merest smatterer in Geology, the auriferous nature of its deposits. That he did not distinctly say "search and you will find," will be sufficiently understood and appreciated by those who are aware that such an announcement, although it might have had the effect of making him the idol of the Stock Exchange, was calculated to render valueless the pastoral property of those hospitable settlers who had received him with open arms throughout the southern colonies. Indeed the precious metal had already been discovered by an old shepherd of the Wellington district, (named MacGregor, if I remember right) who had long been in the habit of carrying with him specimens of gold embedded in quartz on his annual visits to Sydney with his flock of fat wethers. He did not disclose the locality in which he found them, but it was evident that he must have picked them up somewhere on his sheep-walk. In fact the Count must have repeatedly been made aware of the anxiety of the stock holders, who feared that MacGregor's discovery might lead the shepherds to neglect the flocks while searching for the precious metal. This man was as assuredly the discoverer of Australian Gold in the matrix, as was Mr. Hargreaves of the metaliferous deposits; but by far the greater merit is due to the latter, as his discovery was not the result of accident, but of deduction drawn from comparison with the Geological features of the auriferous regions in California.

But the most painful feature connected with the rival claims of the English Geologists, consists in the naturalist who first brought forward the scientific data on which anticipations could be founded being a foreigner, whose admiration of and confidence in the British character, led him to publish the result of his researches in London, under the auspices of one of the rival claimants for the honor of the discovery.

While on this subject, I cannot refrain from allusion to a practice that has recently come to be adopted by travellers;—that of submitting their rough journals to professional amanuenses or book-makers to be worked up for publication. These gentlemen are sometimes in the habit of engraving the observation of previous travellers, who from death or absence may not be in a position to claim their property on those of their principal without acknowledgment, or even the slightest allusion that might lead to references thinking thereby to enhance the reputation of the work they are employed to polish. This principle or rather want of principle has been particularly displayed, in some recent narratives of travellers in the Indian Archipelago. Sooner

or later these literary piracies must be detected, and when some Bancroft or Cooley of the next century employs his talents in separating the grain from the chaff, honorable names will have to bear the odium which should properly attach to those of unknown booksellers hacks.

The areas of the second class invariably extend in a direction corresponding with that of the part of the volcanic band on which they depend. Commencing to the north, the chain of islands which runs along the Tenasserim Coast, from Martaban to the neighbourhood of Penang, is an area of upheaval; and the contiguous coast affords evidence of having been subjected to the same influence. The southernmost point in which upheaved limestone has been detected, is at Pulo Bidan, a few miles to the north of Penang, but it would appear from the projection of the metals in a liquid state, that the whole of the Malayan Range, including Linga and Banka, have been effected by volcanic action. The chain of islands which extends along the west coast of Sumatra is of a similar character to the Tenasserim chain. These islands have been geologically described by Dr. Jack, who inspected the group at the instance of Sir Stamford Raffles when governor of Bencoolen (*Geol. Transactions*, 2nd series, vol. I.) The two areas of upheaval in Java are distinctly defined in Dr. Horsfield's Geological map. Their connection with the volcanic band cannot be doubted. The southeastern extreme of Java, the south point of Bali, and Banditti Island in the Straits of Lombok, are all upheaved table lands, bounded by precipitous limestone cliffs, several hundred feet in elevation. Areas of simple upheaval are found on the north side of the volcanic band at Flat island, Rusa Radgi and Lingit, and at the Iron Cape of Flores.

*Productive Character.*—The excessive fertility of soil which characterises the narrow band in which the volcanic stream is still active, does not extend to the areas in which the circulation has ceased. Nevertheless the fertilizing qualities of decomposed limestone have aided in forming a soil better adapted for the growth of produce necessary for the sustenance of man than the rich, fat, soils of the volcanic band. Maize, upland rice, yams, and other esculent roots here attain perfection, and the nourishing qualities of the produce are apparent in the superior vigour of inhabitants of areas of upheaval. The wheat grown in the uplands of Timor is remarkably rich in gluten, although the small size of the grain gives it an unfavourable appearance in European eyes. The cultivation of produce adapted for commerce is still in its infancy, owing to the lands of this formation having hitherto been neglected in favour of volcanic tracts, but its prospects are by no means disheartening. The coffee, cotton, cacao, and hemp (musa textiles),

growing on the upheaved areas, are the best produced in the Archipelago; although the soil is not calculated to produce sugar, or spice equal to that of the volcanic band. The mineral wealth of these areas is, however, more calculated to attract European enterprise. Coal has been found whenever it has been sought for with diligence in spots favourable for its deposit:—iron ore of excellent quality is abundant where the line of upheaval has crossed primary ranges;—and limestone, so necessary as a flux in smelting the metals, is found everywhere, so that the larger areas possess those elements that have mainly contributed to the prosperity of Great Britain. Fortunately, the gold deposits in the western parts of the Archipelago are now pretty well exhausted, and in the more remote regions, Timor, and possibly Sumba, are the only spots in which the steady course of industry is likely to be interrupted by the search for precious metals. The native chiefs of the former island, terrified by the rapacity of the early European navigators, are said to have combined in establishing a law which made searching for gold a capital crime, except on occasions in which it was thought proper to propitiate the deities by the dedication of a Bulan Mas or golden moon, when a human being was sacrificed to the spirits of the mines before the gold could be collected. This ceremony is probably alluded to in the "Account of Timor," published in Mr. Moor's "Notice of the Indian Archipelago. Appendix p. 6."

The name of the author is not given, and after diligent enquiry, I have been unable to trace his identity; but from the tenor of his remarks I suspect that he must have resided some time at Coupang, and collected his information concerning the more remote island from parties employed in the commerce of its dependencies; otherwise he could not have described Sumba as a low island, not much higher than Madura. Nevertheless I can affirm the general correctness of his observations, as I had Mr. Moor's book with me when I first visited Timor in 1836; and repeated visits during the five following years enabled me to make enquiries upon nearly every point he has brought forward. Mr. Hazart, who appears to have been the Resident of Coupang at the period of his sojourn, was so strongly impressed with a belief in the metalliferous wealth of the southern part of the island, that he would scarcely converse on any other subject, and his incessant appeals to the government led to a commission of enquiry, headed by M. Macklot, an eminent mineralogist being sent to Timor. An overland journey was made with a large party to Pilarang, where abundance of copper was found, but the strata had been so broken up, that mining operations could not have been prosecuted with advantage (see Journal I. A. Vol. IV. p. 495). The reputed

gold deposits, which lie on the south side of the island, were not examined. Quicksilver in a pure state is sometimes brought to Coupang by natives from the interior; and as the collection from the hollows of the rocks in which it is deposited does not entail heavy labour, it might become an article of commerce were its value known.

The Edible Nest which is constructed by the *Hirundo esculenta* in the caverns of the limestone cliffs is found throughout the areas of simple upheaval, but not elsewhere; so that this singular production, which forms its value is well known to those engaged in the commerce of the Archipelago, furnishes one of the best tests for deciding the character of the regions in which it is found.

#### *General Conclusions.*

In venturing to draw conclusions from the fact presented by a study of the Physical Geography of the Eastern Islands, I do not presume to trench upon that prescriptive right to generalize on the notes of travellers, which has for some years past been conceded to leaders of Geological Science, but rather to note those suggestions which naturally arise from extensive voyaging through a region whose physical character is yet undetermined. Until the general outlines, at least, have been ascertained, science must still be indebted to those travellers who have had opportunities of acquiring practical information, for that preliminary arrangement which men of science may extend to a system. That a connection once existed between Asia and Australia, is, I think, established by the simple facts brought forward by Mr. Morris in Count Strzelecki's work; indeed those who asserted contrary opinions in 1845 were (innocently, I am sure) supporting the famous spontaneous-development theory of the "Vestiges of Creation," which was exciting the indignation of the scientific world at the time. The opposition my suggestions then met with is not likely to be renewed, for the leading geologist of the day will scarcely repudiate a region that he has admitted into his own "Silurian" beds; and the Professor of comparative anatomy will probably reconsider the conclusions he ventured to draw from the facts presented by one of the minor branches of a science yet in its infancy.

Nevertheless, the facts established by Professor Owen in his essay on the Fossil Mammals of Australia, will prove of eminent importance in deciding the epoch at which the separation of the continents took place, for although the Professor's zeal leads him sometimes to give too much prominence to the science which he has made his own, no one can doubt the correctness of the practical results he has arrived at. The fact that no remains of mammals of more perfect forms than the marsupials were found among the numerous fossil specimens from Australia

## ARCHIPELAGO OF INDIA.

that were submitted to his examination, shew that the disconnection must have taken place during an epoch in which the marsupial was the only existing form of mammal in Australia and probably in Southern Asia also.

An enquiry into the distribution of the existing forms of mammals throughout the Indian Archipelago will throw some light on this interesting point. Commencing with the species common in Asia at the present day, and excluding those which may have been introduced in a domesticated state, such as the horse, dog, kine, and deer, the common Brown Monkey has penetrated farthest from the continent of Asia, as it extends through Sumatra and the Trans-Javan chain to the eastern extremity of Timor; but the thirty miles of strait which separates this Island from Latti seem to have stopped its further progress, for it is not found in a wild state in the Serwatty Group. To the north it extends through Borneo and Celebes, and is found in a single Island of the Molucca seas, Batchian. This animal, from its habit of frequenting the banks of rivers, is very liable to be carried out to sea in the masses of drift which are sometimes detached from the banks by the current, and its extensive distribution may be attributed to this cause. But such accidents are not likely to happen to the more bulky pachyderms, nor are the frail vessels of the natives calculated to transport them from Island to Island, so that an enquiry into the distribution of these monster mammals will best answer our purpose. In Borneo the Elephant co-exists with the Black Bear, (*Ursus malayanus*); the *Felis macrocelis*, or Sumatra Gigantic Tiger Cat, and so many varieties of the quadrumanes that their introduction can scarcely have been accidental. In Java, the Rhinoceros, the Royal Tiger, the Wild Ox of the Malayan Peninsula, and several varieties of the smaller quadrumanes, still exist in the jungles. Sumatra and the Peninsula contain every form of mammal found in Java and Borneo, with the addition of the Tapir. These facts would go to prove that Java, Borneo, and Sumatra continued attached to the continent of Asia, at a comparatively recent epoch. The common brown monkey is the only member of the family of quadrumanes that has reached Celebes and Bali, although the strait which separates the latter island from Java is only two miles wide.

We will now trace the range of the marsupialia from Australia towards the continent of Asia. A variety of the Kangaroo (*macropus*), two varieties of the Opossum (*didelphis*), one of which closely resembles the Ring Tailed Opossum of New South Wales (*Phalankista Cookii*), one variety of the *Dasyurus*, the Native Cat of the colonists of New South Wales and Port

## ARCHIPELAGO OF INDIA.

Opossum, have been found in the southwest part of New Guinea; and singularly enough the Kangaroo has adapted himself to the half-crowned nature of the country by inhabiting the trees. A variety of the Kangaroo still exists at Arru Island, which seems to be identical with the small Grey or "Brush" Kangaroo, found in the thickets throughout Australia. This is the "Filander" of Valentyn. The name by which it is known in the Moluccas is "Pilandook." In Ceram, the Ring-tailed Opossum, the Native Cat, the Flying Opossum, and the little Flying Squirrel, all marsupials, and identical in appearance and habits with those which extend throughout Australia, hold undisputed possession of the forest trees. The Ring-tailed Opossum, which is the most numerous, as in New South Wales, is a common pet throughout the Moluccas. The opossum, more especially the Ring-tailed variety which inhabits trees, is the most hardy of Marsupials, that is to say its geographical range is farther extended than that of any other pouched animal. The tree opossum and the native cat (*Dasyurus macrourus*) are the only varieties of this ancient form of mammals that have not retreated before the European quadrupeds that have been introduced into the southern districts of Australia; the mere presence of a flock of sheep, without their usual attendant, the dog, being sufficient to drive the Kangaroos from the "runs." The tree opossums are not liable to be disturbed by any animal less agile than the monkey, as they are never seen on the ground except when thrown out of the trees while fighting, and then they scramble up again as fast as they can. The consequence is that the tree opossums now abound in the settled districts of Australia to an extent that could not have happened previous to the arrival of Europeans, when the aborigines kept down their numbers by dragging them out of their nests in the hollows of trees to serve as food. Even the presence of the monkey is not fatal to the tree-opossum, as is evident from their co-existing in Timor and in parts of South America. The Musang or Mongoose of the western parts of Archipelago, will prove fatal both to the tree-opossum and to the Native cat, whenever he comes to be introduced to Australia, as he can enter the hollows of the trees and destroy them in their nests. The tree-opossums of Australia feed on the leaves and tender shoots of the Eucalyptus. In the Moluccas, where the Eucalyptus is rare, if found at all, the tree opossums feed on the leaves of the Warringin and Lingoa trees, and on the outer bark of the Kamari. As the two first exist in the Malay Peninsula, the latter under the name of Angsannah, the absence of the tree-opossum from this part of the Archipelago cannot be attributed to want of suitable

## ARCHIPELAGO OF INDIA.

in the northern part of the Malay Peninsula, with a view to the discovery of fossil remains of mammals, might be attended with very interesting results, for although the rock has been of subaqueous formation, as evidenced by the existence of fossil shells, still the remains of mammals may be found there, as well as in the caverns of the same formation in Australia. Such an examination is not necessary to shew that marsupials once existed on the continent of Asia, that point having been decided by their appearance in the secondary beds of Europe; still it would be a matter of great interest to science were their remains discovered in the southern parts of Asia.

The Malayan name is "kusu" which has been latinized by the old Dutch naturalists into "Cuscus," and I am sorry to see that this barbarism has been adopted by modern Zoologists. In Timor the Ring-tailed Opossum is common in the Southern parts of the island. The only marsupial that has yet been traced in Celebes is the Flying Opossum, but the Zoology of this island still remains to be explored. The Zoological connection of Java, Sumatra, and Borneo, with the continent of Asia, is as distinct as that of Timor, Ceram, and New Guinea, with the continent of Australia. Probably Celebes will be added to the Australian group, but until its Zoological character is more fully ascertained, it will be safer to allow it to remain neutral ground. The inferences to be drawn from these facts must be self evident.

Those who are acquainted with the process which is still going on in the volcanic bands of our immediate neighbourhood, will be unwilling to entertain the opinion that the subterranean action which has influenced tracts so remote from each other, can have been exerted simultaneously. The only test that I have been able to discover which is likely to prove applicable to the determination of the comparative antiquity of the epochs of upheaval, is that which must be familiar to those who have had "transactions" in gold dust in this part of the world. Proficients in the art of ascertaining the "touch" of specimens of native gold, by the colour that it leaves when rubbed upon a smooth black pebble, assert that the comparative value of gold is determined by its age, which I suppose means the comparative antiquity of the period in which it has been deposited in the alluvium. This test appears rather fanciful, but it is certain that experienced "touchadars" can detect in a moment the difference between Pahang and Borneo gold.

But this is a point of no immediate interest to physical geography, although, if followed up by an assayer, it might be productive of useful results in determining the course and progress of former volcanic currents. It is by no means improbable that recent researches in electricity,

## ARCHIPELAGO OF INDIA.

which have been pursued with such vigour for some years past, may have developed laws which regulate the volcanic currents, although the fact is yet unknown in these remote regions. It is evident that the volcanic band has shewn a determined obstinacy in breaking across the primary ranges, and a tendency to run along the outermost range when it had succeeded. I have already alluded to a volcanic band which extends south from Japan through the Bonin and Mariana or Ladrone Islands. In the absence of any evidence to the contrary, I have long inclined to the opinion, that this band, prolonged through the Carolines to New Ireland and the New Hebrides was the first line of attack, and that spurs extending from the Solomon Group to the neighbourhood of Moreton Bay; and from the New Hebrides through Norfolk and Howe's Island to the coast near Sydney, produced the upheaval of the south eastern part of that continent, and broken through Bass Strait:—that a branch from this line precipitated itself directly on the coast of New Guinea, the minor currents which extend to the northwest extreme of the Gulf of Carpentaria, and along the Timorean area, being a continuation:—and that a second branch broke off from the Ladrone through Egoi, Yap, and the Pellew Islands to Celebes; but an examination of the islands lying between the Ladrone and New Guinea, with the express object of tracing the course of the volcanic band, will be necessary before conclusions can be arrived at. From this point, however, I can proceed with a tangible foundation. The distinct character of the mammalian forms existing in the countries lying on the Great Asiatic Bank, shew that Borneo, Java, and Sumatra, were attached to the continent of Asia by an unsubmerged range at a period long subsequent to the separation of Australia; which would imply that the curved band that passes from Formosa through the Philippines, the Moluccas, Java and Sumatra, is the most recent line of volcanic action.—George Windsor Earl in No. VI Jour. of the Indi. Archipelago and Eastern Asia, May 1882, pages from 244 to 272.

The Indian Archipelago possesses an extraordinary abundance and variety of materials for elucidating the most interesting and the most intricate questions in ethnology. A complete account of the different races by which it is inhabited would furnish results applicable to the investigation of the connection of races in every other region of the world.—No. IV. Oct. 1847. Jour. Ind. Arch. page 171.

In the Archipelago we can never free our researches from Continental elements. The history of the nations along the southern borders of Asia has in every era exercised some influence on the Archipelago, and we may be

## APOCYNACEÆ.

sufficiently impressed with the difficulty and importance of the international influences of the Archipelago itself, when we consider that while some writers have derived Malayan civilization from an original source in Menaangkaban, others have referred it to Java, and others to Celebes, while two of the ablest,—Mr. Marsden and Mr. Crawford,—have busied themselves in endeavouring to exhume a great nation whose civilization preceded the Javanese, the Malayan and the Bugis, and impressed itself more or less not only in the Archipelago but over all Polynesia.—*Ibid.* p. 178.

Mr. Crawford mentions in a letter that he had just completed an essay “on the races and languages of the Archipelago and Pacific Island,” was read to the British Association at its last meeting at Oxford. “The theory of Marsden,” says Mr. Crawford, adopted by Humboldt and others, of one original language prevailing from Madagascar to Easter Island among all the nations not negro, and the identity in race of the brown-complexioned men within the limits in question, is wholly groundless, and a main object of my essay is to refute it. In a dictionary of the Madagascar of 8000 words the number of Malay and Javanese words is only 147;—in one of the New Zealand of 4550 words, 103;—in a French one of the Marquesas and Oman of 3000 words, about 70;—and in a Spanish Dictionary of the Tagala of the Philippines of 9000 words, about 300.—*Ibid.*

(133) AGELIA. A wood of this name, was exhibited at the Madras Exhibition of 1857, and was deemed deserving especial notice being supposed by some to be the Indian Cedar wood “*Aquilaria Agallocha*.” This is a light colored wood with a fine even grain, appears admirably adapted for furniture and many domestic purposes. It is said to be abundant in Malabar and has been already used for a variety of purposes by the Railway Engineers. The jury recommended some further enquiry regarding this tree, the extent to which it is found in Malabar, and whether known in other parts of the country. Madura 1247, Malabar 2737, Mysore 2254.—*M. E.* of 1857.

(134) APOCYNACEÆ. LANCE-WOOD OF MAULMAIN. There is a tree found all over the Provinces which yields a wood that the residents at Maulmain sometimes call lance-wood. The Karens make bows of it, but prefer *Cassia fistula*. Mr. Mason had never met with the tree in flower, but thinks it a species of *dalbergia*, though it may possibly be a *cassia*.—*Mason*.

At another place he says, the tree which produces a timber possessing the properties of lance-wood is not uncommon in the Provinces, but it belongs to the dog-bane tribe, and is not at all

## ARACHIS HYPOGEA.

related to *Guatteria virgata*, the lance-wood of commerce.—*Mason*.

(135) APONOGETON MONOSTACHI-ON, Thunb.

*The root.*

Cottie kalung, TAM.

The plant is commonly found growing in the beds of tanks. Thunberg in his “Travels,” tell us, says Ainslie, that this root is eaten in Caffraria, as a great delicacy: it does not appear to be less relished by the Natives of India.—*Ainslie*, p. 248.

(136) AQUAMARINE. At the Madras Exhibition a good specimen of Aquamarine, or Beryl, was contributed by Lieut. Puckle from Mysore: other samples of long reed like crystals were forwarded by the Nellore Local Committee; small pieces of Amethyst, Tourmaline, Rock crystal, Agate and Cornelian were exhibited from Masulipatam.

(137) AQUATIC BIRDS are largely brought to the markets of the principal towns of India, at certain seasons of the year, ducks, teal &c., and may be procured in abundance.—See WATER FOWL. C. of I.

(138) ARACHIS HYPOGEA, Lin.

*The Nut.*

Vayr Cadalay, TAM.

Naylasanizheloo, TEL.  
Cachang goring, SUMA.

Moong phullie, MAHRATTA,  
Manilla gram or ground nut.  
Boochanaka, SANS.

It is generally toasted before it is eaten and is extremely palatable.—*Ainslie*, p. 234.

*The Oil.*

Vayr-cuddala-yennai,  
TAM.  
Manilla noona, TEL.

Willayetie-moong-kie phullie-ka-tael, HIND.  
Ehoysing ka tael, HIND.

This valuable oil, which of late years has been exported to a large amount, is obtained by expression from the seeds of the Ground or Manilla nut, which is now cultivated to a considerable extent in most parts of the Peninsula of India.

In the year 1848-49—37,000 gallons were shipped, but in the two following years the Exports exceeded 1,00,000 gallons. It has however fallen to 57,207 gallons in 1852-53.

It does not seem to be consumed to any large extent in this country, although the nut itself is much eaten by the poorer classes. It is said to be used for adulterating gingely oil in North Arcot, where it costs from Rs. 1-8-0, to 2-12-0, per maund. In the Nellore District, the seeds are procurable at Rs. 1-8-0, per maund and in Tanjore about 200 acres are cultivated, producing annually 75 candies of oil at Rs. 2-6-0 per maund.

The seeds yield about 43 per cent. of a clear straw coloured edible oil, which is an excellent substitute for olive oil, and makes a good soap.

## ARTOCARPUS INTEGRIFOLIA.

Its value in London in January 1855 was £17-10 per ton.—*M. E. J. R.*

(139) *ARALIA PAPYRIFERA*. The source of the product known as Rice Paper continued long a matter of doubt, but it is now equally certain that it is produced from the *Aralia papyrifera*.—See *Paper-Rice and Rice Paper*. C. of I.

(140) *ARASA NAR. FICUS RELIGIOSA*.

(141) *ARTABOTRYS, R. B. POLYANDRIA-POLYGINIA*.

Artao, to suspend, botrys, a bunch, the peduncle has a curious hook, which lays hold on any support near and assists in bearing up the clusters of fruit.—*Gr. Cat. p. 3 and 4.*

A scandent shrub with shining leaves, and very sweet smelling flowers.

In gardens Bombay, as an ornamental plant.—*Gr. Cat. p. 4.*

The flowers of the *Artabotrys odoratissimus* and *Unoua odorata* are extensively cultivated in China for their perfume.—*Williams*.

(143) *ARTOCARPUS INTEGRIFOLIA*. JACK.

### The Tree.

Pilla Maram, TAM.	Hansa Vriksha, CAN.
Panasa Chettoo, TEL.	Kantal, BENG.

Mr. Rohde says this tree is cultivated in every part of Southern India. On the Malabar Coast, it attains to great size, the wood is very like Mahogany but splits in hot dry stations; from the juice of the uneatable parts of the fruits and tender parts of the tree, a good bird lime is prepared. The kernels of the seed toasted are nearly as good as chestnuts, the fruit is also used by Europeans soaked in salt and water.—*Rohde, M. S. S.*

### The Fruit.

Peela pullum, TAM.	Chopada, SEMATRAN.
Punnus, DUK.	Boon Nanea, MALAY. JACK.
Panasa pundoo, TEL.	Panasa, SANS.
Tsjacka, MAL.	

This fruit is not relished by some people owing to a peculiar strong smell that it has: others are extremely partial to it from its luscious sweetness. Aghastier, in his work on diet, says that it is apt to increase the secretion of bile, and if frequently eaten, will produce dyspepsia. The fruit of it sometimes grows from that part of the trunk which is underground and by its growth bursts the soil and discovers itself. These are always accounted to be the best.—*Ainslie, p. 230.*

## ARTS AND MANUFACTURES.

(144) *ARGEMONE MEXICANA* BRUMADUNDOO OR COOROOKOO OIL.

### The Oil.

Brumadundoo yennai, TAM.	Oil of Prickly Poppy, or
Ernamundie Nootia, TEL.	Jamaica yellow thistle,
Parangie datura ka tel, HIND.	Eng.

This pale yellow, limped oil, may be obtained in large quantities from the round corrugated seeds of the prickly poppy, which was originally introduced from Mexico in ballast, but now flourishes luxuriantly in all parts of India. It was noticed under the head of *Argemone mexicana*. It is sometimes expressed by the natives and used in lamps, but is doubtless adapted to other and more important uses. In North Arcot it costs from Rs. 1-14-0 to Rs. 2-1-0 per maund.—*Madras Exhibition of 1855.*

(145) *AROMATIC ROOTS*. There are several kinds of aromatic roots found in Malabar, the products of various species of *Curcuma*, *Zingiber*, *Costus*, *Kempferia* &c. M. C. C.

(146) *ARTIES* in Madras, timber of various sizes 12 to 18 feet long and from 1 to 1½ feet in breadth.

(147) *ARSENIC, WHITE OXIDE OF, Eng.*

Warangan patih, MALAY.

(148) *ARSENIC, SULPHURET OF, or ORPIMENT.*

Warangan or Burangan, MALAY.

Dr. Helfer reported the existence of ore of arsenic on the Mergui Islands, Mr. Piddington found it in the antimony ores, and Professor Mitchell also found arsenic in the lead ore that he analyzed.—*Mason*.

In China the sulphuret of arsenic is sometimes cut into ornamental figures in the same manner as prehnite and agalmatolite.—*Williams, p. 248.*

(149) *ARRACK*.

Charayum, TAM.	Khulloo TEL.
Arruk, Arab. HIND. and	Arrack appee, MALAY.
DUK.	Arrack, ARRACAN.

*Ainslie's Mat. Med. p. 140, 268.*

(150) *ARSENIC. RED ORPIMENT, REALGAR.*

Kudireipat Pashanum, TAM. | Mansil, HIND.

Mr. Elphinstone mentions orpiment being found at Bulkh in Cabul. The yellow orpiment is an article of trade from China and Burmah where the red is also procured and from Japan. The red is common in the Bazaars, a coarse description, "manocilla" Tam, "ustarkhy" Arab, is frequently exposed for sale in the bazars and is used only as a pigment.—*Rohde, M. S. S.*

(151) *ARGYREIA SPECIOSA* SAMOODRA PALACCA.

(152) *ARTS AND MANUFACTURES*. The Bombay Committee for the collection of

## ARTS AND MANUFACTURES.

specimens for the Great Exhibition of 1851 resolved to enhance the value of their collection by accompanying it with as large an amount of statistical and descriptive information as they could procure: and the written portion is not unlikely in this case to be one of the most valuable of the results of their labours. The difficulty in breaking ground in such matters as these, is to secure anything like an approach to accuracy at the outset—If we wait for even an approximation to perfection we shall never be able to make a beginning; and the great thing is to strive to give an outline at all events—anything is better than nothing,—correcting and filling in as we advance. It has, under these circumstances, occurred to us that we might do some service to the state, and impart some instruction and some amusement to our readers, by attempting to give the outpourings of a promiscuous and tolerably well-filled notebook, in the shape of a series of notices of native art and manufacture as they prevail at Bombay,—confident that, imperfect as on many occasions our information will be found, it will not prove wholly uninteresting to our readers, and convinced that there are many amongst them who will readily fill up what is wanting, and correct what is wrong, who would scarcely take the trouble of drawing up a paper or notice on the matter to be described. Our first concern is of course to enlighten or to please our readers; but if in doing this we shall be able to assist the Committee in any way, the gratification we shall derive from our efforts will be doubled. We shall endeavour mainly to address ourselves to the processes which are new or have not hitherto been described in books: when we find descriptions scattered through several works, or others which furnish an imperfect account of the matter, we shall abridge or extract, as may seem most meet, as we advance. We shall commence with an attempt to describe Turning, as practised by the natives:

(153) *The Turning-Lathe of India.*—There are few implements more generally known, more simple or efficient, or better suited for native habits, where the workman always sits on his hams by preference if this is possible, than the Native Turning-Lathe. The simplest form of the lathe consists of two pegs or pieces of wood driven into the ground, with a short iron peg projecting from each inwardly; these constitute the centres. When the centres get slack, the pegs, or heads of the lathe as they would be called, are driven a little firmer and further in: or should this not suffice, the pegs are pulled up and driven into fresh ground. The rest consists of a cross piece of wood with a handle like a wooden mattock or coal-rake. This is placed in front of the lathe and steadied by the foot. The work to be turned is spun backwards

## ARTS AND MANUFACTURES.

and forwards by a bow held in the right hand: the tool is managed with great dexterity by the left hand and foot, the rest being steadied by the right foot. The native workman is almost literally quadrumanous, and can make his feet and toes almost as serviceable as his hands and fingers. The lathe costs about Rs. 2, and a native workman will turn out on this as much rough work as an Englishman will on the best foot-lathe. The tools mainly consist of short bars of steel sharpened at both ends, each end being used alternately; an old file, or anything else that will cut. They have seldom a good edge—they are set on a fineish-grained sandstone, not capable of making them very sharp.

A better variety of lathe has the two heads coupled together by a bar, and made fast by wedges: the other arrangements are the same in both. From these two, bed-posts and pieces of wood from a quarter of an inch to eight inches in diameter are turned out. Instead of being painted, the works are lacquered on the lathe by holding on a piece of resin coloured with some mineral paint. They give in this way, at a most insignificant price, the effect of highly polished varnished work. The lathe with one centre and chucks for turning hollow cups and fancy work, is a much more perfect and highly finished implement than the lathes of two centres. It consists of a strong platform of wood, from two to three and a half inches thick, and one by one and a half or two feet square. The heads are morticed into this: an iron post secures the spindle end—the other works with a wooden collar and washer. The chuck is fastened on without screwing. Like the other lathes, it is worked with a bow, but the bow itself in this case is a neat and well finished implement. The tools and mode of working are the same, or nearly so, in all. In this lathe, the most beautiful ebony and ivory work is turned with singular neatness and speed; and we should say a native would beat any European with this variety of implement. It is astonishing to see with what celerity they turn off beads, spheres, balls, boxes, backgammon men, and plain chessmen,—for each of which half a dozen of turns seem to suffice.

(154) *Fish Oils of India.*—The manufacture of Fish Oil is practised all along the western coast: we are not in possession of any trustworthy account of the amount or of the value of the manufacture. The extreme cheapness of cocoanut, castor, and other vegetable oils, interferes with the productiveness of animal oils. The great source of supply is the shark and the skate: the livers of these are cut out, and thrown into a vat or old canoe, or other receptacle, and trodden on with the feet till the oil is expressed. It is then drawn off, and stowed away: boiling does not seem to be resorted to, as there is little or no muscular fibre, such as that of the blubber.

ber, to be got rid of, or aqueous particles to be dispelled. The amount of oil manufactured at each fishing-village will, in all likelihood be found very nearly proportioned to the value of the trade in sharks' fins. The oil from the variety of skate called "Wagil" by the natives, seems to have a strong resemblance to the cod liver oil now so much in demand for medicinal uses. On the Malabar Coast, especially off Vingorla, the seas literally swarm with a variety of the sardine: a coarse ill-smelled variety of oil, which sells for from six to twelve annas a maund, is manufactured from these—the natives employ it for smearing their boats. This is all the information we at present possess on the subject: we give it, meagre as it is, in hopes that we may be enabled speedily to encrease it.

(155) *Salt*.—One of the most extensive manufactures on the western shores is that of Sea Salt, and, simple as the process seems, it is far from devoid of ingenuity or interest. Amongst the numerous islands which fringe the Malabar Coast, there are countless narrow, creeks and inlets, left dry at low tide, the expanse of mud then exposed being often enormous. Off the shores of Sewree the tide at springs retires nearly two miles: and this is nothing at all out of the way in the neighbourhood. When salt-pans are proposed to be established, the first thing is to construct a mud embankment,—a foundation for it being selected where the water is never more than four or five feet deep. The crest of the embankment is made to surmount this by two or three feet—the base of it is generally from two to three times its height. Openings are purposely left at intervals in the principal embankment, and from these, at right angles to the main line of the wall, other embankments are run inland, parallel to each other, leaving a current between large enough to admit of a line of salt boats running up. Immediately behind the embankments the salt-pans are laid down. These consist of rectangular compartments, from twenty to thirty feet across, and commonly twice as long as they are broad, and from a foot to a foot and a half in depth. They are separated from each other by little mud walls, about three feet across at bottom, and two at top, more or less, according as little channels for filling the pans are meant to be run along them or not. Two, three, or four, lines of pans, according to the extent of the back water, are carried along the rear of each embankment—care being taken to leave an area of land capable of being flooded by the sea betwixt the pans and the mainland, three or four times the size of the pans themselves. So soon as the monsoon is fairly over, all the fresh water that has accumulated in the pans or back water is run off, and in November or December the sea is admitted to the back water through a sluice

in the embankment. The pans are now carefully cleaned out, their floors and walls being made smooth and nice. In about a month after it has been admitted to the back water, the sea-water, now getting reduced in quantity, and encreased in saltiness by evaporation, is let into the pans. The first charge requires about six weeks to evaporate: subsequent charges are dried up in half the time of the first, thus diminishing as the season becomes hotter, and the brine more strong. The strength of the brine is judged of by its becoming red: in fact, a curious variety of creature, of the volvox kind, which seems never happy unless in a pickle—the same as is to be found in a fossil state in the Punjaub rock-salt, and which often tinges the waters of our seashores as if stained with blood,—makes its appearance just as the salt is ready to crystallize,—often tinting the salt itself of a fine pinkish hue. When very nearly dry, the salt, which has now accumulated to the thickness of an inch or two, is raked off, the upper portion, which is beautifully white, and almost quite pure, being first taken,—the lower portion, often crystallised in pieces of half an inch cube, is taken up next,—is slightly mixed with clay, and is that generally in use. The white and bluish salt are now piled up separately in conical heaps, about sixteen feet in diameter, and ten feet high, which are preserved with a thick thatching of grass during the monsoon. The white salt is as pure as any in the world—the black salt is mixed with about one or two per cent of clay. Both are in a great measure free of the magnesian salts and sulphates which contaminate pan-made salts at home;—everything more soluble than muriate of soda remaining behind in solution, is washed away by the rains. Salt-pans are much less efficient when new than afterwards, and they continue to improve as the ground becomes impregnated for ten or fifteen years. When the first crystallisation is unsatisfactory, as it often is, a second charge of brine is let on before the salt from the first is removed. The evaporation in the back water goes on, of course, as rapidly as in the pans themselves, and by this contrivance, which requires no care or preparation, an amount of evaporating surface three or four times that of the pans is secured: the pans themselves only require trouble or attention, the back-water require none. The pans are drawn from three to four times every year: as the rains approach, they are abandoned for the season. The sea is seldom let in more than once or twice into the back water: were the whole available surface kept covered, double the amount of salt at present manufactured might be made. The supply, however, is so close on the heels of the demand, and the profits are so very low, that there is no reason why production should be extended. Such is the convenience of our shores

for the manufacture, and so easily and so cheaply can the process of storing and carrying away be managed, that all the attempts made by Baniyas to bring salt from Scinde, where it is to be had in unlimited quantity ready made, have proved unremunerative. The idea, therefore, of importing salt from England into India is about as chimerical as any that ever entered the human imagination; while the abuse heaped on the quality of the salt used in India is as unreserved as may be. The upper salt is scarcely surpassed in purity by the finest the Cheshire mines send forth: while the black salt contains as much of the pure muriate of soda as does the common pan-made salt at home. The matter which contaminates the former is conspicuous, and looks very dirty, but then it is perfectly harmless: the subtle contaminants of the latter are eminently mischievous, though invisible. An English adult is supposed to consume at an average of from fifteen to twenty pounds of salt annually, so that he will in this way swallow some three ounces of mud a year: it will be a long time before the peck of dirt every one is said to have destined for him in the course of his lifetime, be at this rate consumed: in India, numbers of people eat pounds' weight of clay by choice! See SALT SUP. C. of I.

(156) *Cements*.—The instructions sent from home for the guidance of the Indian committees for procuring materials for the Exhibition of 1851, required amongst other things an account of cements and building stones. Our only cement here is chunam in its various forms: the only building stones, which differ materially from those of the rest of the world, are laterite, concrete and kunkur; and of each of these a short notice may interest the reader.

It is remarked by Humboldt, that however widely the aspects of Nature may differ from each other in other respects in various quarters of the world, we find the great geological formation, everywhere very nearly the same—the same rocks, bearing the same appearances, constituting the leading features of the landscape throughout. The remark, so far as India is concerned, must be received with modifications, and two of the varieties of rock we have named, if not all the three, are either unknown in the other quarters of the world, or have not hitherto been described by geologists. The names of laterite and kunkur are not to be found in the indices of our most recent manuals. Kunkur is described as a variety of limestone mostly nodular—always fresh water and recent,—in most cases in the act of being formed under our eyes. The following list of papers on the subject—which may, so far as we know, be very incomplete—shows that there is no want of pub-

lished information in reference to Kunkur did European geologists choose to seek for it:—

Colonel Sykes on Kunkur. London Geological Transactions.—Prinsep's Analysis of. Ibid.—Newbold's account of, Bengal Asiatic Transactions, 1844. Vol. XIII., p. 317. Old or travertine variety from specimens used—same as that around Rome. Ibid.—Formation now in progress same as calcareous formations on shores of Red Sea. Ibid.—Newbold's Geology of Southern India. London Asiatic Transactions, 1845. Calcutta Review, 1843.—Captain Abbott's account of—as prevailing in upper Bengal—sheet kunkur, nodular kunkur, fragmentary kunkur. Bengal Asiatic Transactions, Vol. XIV., Part I, 1845, page 443. Theory of Formation Ibid, p. 444.—Soda Soils reposing on beds of, near Barramahal, Captain Campbell's account of. Bombay Geographical Transactions, 1840-44, Vol. III., page 165.

It is sometimes found in thick stratified beds like the travertine near Rome, and seems in this case to have been formed by calcareous springs: more generally it is met with in clay or alluvial soil, in the shape of small pieces from the size of pease or filberts to that of the hand. In the blue clay which stretches along all our shores, it is found in vast abundance, generally assuming the most fantastic forms—indeed it abounds in every rice-field and open soil all over the country. The more recent varieties seem to be formed by the agency of the rains: when the earth abounds with vegetation, the tepid waters are charged with fixed air and dissolve the lime prevailing in the soil everywhere around,—the mineral being again thrown down as the advancing season dispels the excess of gas. It in this state absorbs the clayey matter around, and cements it into kunkur. This is collected by the lime-burner, placed with firewood in small-sized conical kilns, and burnt in the usual way. It contains 72 of carbonate of lime, 15 of sand, and 11 of clay and oxide of iron. Mixed with half its weight of river sand, it makes an excellent mortar: burnt in pieces of a cubic inch or so in size, and then powdered without slaking, it forms a first rate water cement, setting in a few minutes, and becoming as hard as stone. At Poona the finer varieties of kunkur are burnt with charcoal all throughout the city, in neat pigmy looking kilns 2½ feet high and about as much in diameter at the base. These hold about a cubic foot of material, or about 30lbs. of charcoal and kunkur in equal parts. When burnt, it is slaked and then made up into bricks, which are sold in the bazaar for the purpose of whitewashing. The finer kinds of chunam on the coast are made from shells, brought chiefly from Rutnagherry. The process of burning is a peculiar one—the operation may be seen in progress all along the shores of Salsette and Trom-

## ARTS AND MANUFACTURES.

bay. A piece of ground about ten feet square is laid down even and floored over with clay: an upright pole is placed at each end of this, and a sheet stretched out with back stays spread between the poles, which are steadied with strings. On the floor a bed of shells and rice-chaff alternately, about ten inches thick and eight feet by six, is spread neatly out. Some firewood is placed along the windward side of this, and when the sea-breeze sets in the wood is kindled. As the heat extends to leeward, and the shells become calcined, the limeburners draw off the fore part of them with a stick, and so soon as they have cooled on the floor sufficiently to allow them to be handled, they are placed in a scoop basket and the dirt and epidermis winnowed from them. The shells, now white and pearly, are next thrown into a small sized vat partially filled with water: here they for some time boil from the effects of the heat and slaking. The whole in a short time settles down into a fine semi-fluid mass, which is taken out and slightly dried, and is now ready for use. For the modes of manipulation by which such beautiful effects are produced at Madras, See CEMENT, C. of I.

(157) *Building Stones*.—To pass from cements to building-stones—we first come to Laterite. And should any of our readers feel desirous of more enlightenment than they possess in reference to this most singular formation, they will find it in abundance in the papers the titles of which are subjoined. Dr. Cole, in the introduction to one of the ablest of these, remarks as follows: “In the volume of reports for 1831–32 of the British Association for the advance of Science occurs the following passage in the report on Geology by the Revd. W. D. Conybeare:—‘We learn that primitive formations in which granite bears the principal proportion, occupy not only the Great Himalayan northern chain but also three fourths of the entire peninsula, from the vale of the Ganges below Patna to Cape Comorin: although these rocks are frequently covered with a thin crust of laterite, a ferruginous clay which is connected with the trap formation.’ Now that so little should be known concerning laterite, a mineral so extensively diffused; and offering so peculiar a feature in Indian geology, constitutes an opprobrium to the science, which it is desirable to efface.”—*Madras Literary Transactions*, 1836, Vol. III. The English geologist seems just as ignorant and heedless of laterite now as he was twenty years since: and in India, though we possess an enormous body of information regarding it, we are still undetermined as to what it is—whether it be a sedimentary rock, the efflux of mud volcanoes, or decayed trap re-integrated into rock.—List of Papers published on Laterite:—

Found in boulders or detached masses on Bombay, Salsette, Elephanta, and Trombay—

## ARTS AND MANUFACTURES.

in blue clay, at Sewree. Dr. Buist on, Bombay Asiatic Transactions, 1850.—In borings at Calcutta, Bengal. Asiatic Transactions, 1837. Madras Literary Transactions, Vol. VII p., 477.—Lignite found in, by Captain Newbold, Dr. Balfour on, Bengal Asiatic Transactions, Vols. XIII. and XXXIV.

A very good summary of the whole question will be found in the *Calcutta Review* for 1848, Vol. IX. page 314. This rock, as already stated, seems peculiar to India. It covers the western coast almost continuously, and for the most part up to the very foot of the ghats, and from close by Bombay to Ceylon. It is found in detached beds along the Coromandel coast, near Madras and Nellore, Rajahmundry, and Samulcottah, extending into Cuttack. It caps the loftiest summits of the eastern and western ghats, and some of the isolated peaks in the table land in the interior. It occurs in the Southern Mahratta Country, Mysore, Salem, Coimbatore, South Arcot, the Carnatic, and Tanjore: it is found in Malwa, and in many parts of Bengal and Ceylon. It fringes the shores of Burmah, Malacca, and Siam, and appears on the coast of Sumatra. It is found in boulders and rolled masses all along the Malabar Coast from Bombay north to Gogo in the Gulf of Cambay, beyond the region of the formation itself. Pieces of it have been met with three hundred feet under the surface, in the blue clay-beds at Calcutta, as also in similar beds of lesser thickness in Bombay, and close by Cambay and Kurrachee: so that the formation at one time was probably much more extensive than at present. Its colour is of a red iron or brickdust hue, sometimes deepening into dark red. It is marked with whitish stains, and is occasionally cellular or perforated with tubiform holes. It rarely if ever contains either crystals or organic remains, is never stratified or columnar, and generally spreads out in vast sheets on the surface of the plutonic or volcanic rocks. When the upper surface is cleared away, the rock below is found soft and easily cut into blocks of any form. It quickly hardens and darkens in hue by exposure to the air, and is not at all liable to decomposition or injury from the weather. The Arcade Inquisition at Goa is built of it, and also the old fortress of Malacca. Newbold.—*Asiatic Transactions*. A curious variety of trap-tuffa, sometimes white sometimes greenish or purple, found in Bombay and many other parts of India, resembles laterite in the quality of being easily cut when raised, afterwards hardening on exposure to the air. It is used as a building-stone, and suits well for basins, troughs, and aqueducts: it is not very extensively employed.

*Littoral-concrete* is a variety of rocks which has not hitherto found a specific place in our

geological catalogues:—the name has been conferred on it from its being invariably found close by the seashore, and from its resemblance to the artificial stone formed by the cementation of sand, gravel, or other coarse material, by lime-water or mortar. It is composed of the material prevailing on our shores—of shells, sand, gravel, and pebbles, and varies in its character with the rocks in the neighbourhood,—being micaceous towards Cochin and Tellicherry, from the quantity of sand and other nodules from the granite and gneiss, gravelly to the north of Bombay, and around us composed almost entirely of fragments of shells. (Sir Erskine Perry states that this strange variety of rock is to be found all along the Himalayas, and prevails extensively in Southern India. We have not observed it mentioned by any of our geologists, but have no doubt of the correctness of the statement of the Chief Justice.) It is to be met with only in the regions where rains abound. Along the shores of Scinde, Arabia, and the Red Sea, though the material composing it is abundant in a position similar to that in which it exists on the Malabar Coast, it is nowhere cemented into stone. Even here, indeed, the cementation is far from invariable: in one part of the esplanade we have loose sand at the surface, and concrete beneath: at another, sand or concrete as the case may be, from the surface throughout to the rock: and in a recent excavation, concrete was found for the first twenty feet, resting on a bed of fine sand perfectly loose. It is frequently found to rest—as, for example, at Sewree and Mahim—on a bed of blue clay filled with kunkur and mangrove roots, offering evidence of a depression from the time the mangroves grew at high-water mark, so as to permit the gravel deposit to accumulate. The whole must then have been raised by a second upheaval to its present level. Our principal quarries of these are at Versova, about twenty miles to the north, where the shore is sheltered by a vast dyke of basalt formerly submerged.

The sand, which seldom extends more than few inches down, is first removed, and the rock is smoothed on the surface. A space about twelve feet each way is next divided into slabs one foot square,—the grooves between them being cut with a light flat-pointed single bladed pick. These are raised successively by a tool something between an adze and a mattock, a single stroke of which is in general sufficient for the detachment of each from its bed. The blocks thus cut out and raised being thrown aside, the bed is once more smoothed, and the operation resumed till the pit reaches the depth of six or eight feet, when, it being no longer convenient to remove the stones by hand or basket, a new pit is cut. This variety of building material is brought in vast quantities to Bombay where a

large portion of the native houses are built of it. It is not very strong, but with the admirable cement employed with such lavish hand, it makes a good and economical wall.

We must not conclude this without noticing the native sledgehammer employed in breaking trap, granite, limestone, and the other numberless varieties of rock,—and one of the most efficient tools—that can be made use of. Its handle is generally of male bamboo about two feet long: its head is something like that of an ill-shapen axe—thick all along. It weighs about eighteen pounds. In the face or striking portion is a bluntish wedge of steel, fastened in with a piece of leather. With this the native quarryman will break up the most obdurate trap into slabs or blocks of almost any size or form, from a pavement flag three inches thick and two feet square, to a block two feet cube. He looks narrowly at the grain of the stone, and then with a series of blows, of no great force apparently, literally cleaves the stone, which falls in pieces apparently without effort. Similar varieties of this, of exactly the same pattern, are used as hand-hammers—they are called Sootkees.

The blasting, or rather the boring tool, or jumper, is a plain round rod of iron, about three feet long, pointed at both ends with steel. No hammer is ever employed in boring: the jumper is raised and struck in with both hands, and a man will penetrate some inch or two in an hour. Stones are usually paid for to the quarry owners at so much for each jumper at work.

The native punch is a short dumpy lancet pointed tool—it is sharpened by being turned point up, and struck with a piece of flint. When used in stone-dressing, it is held in the left hand, and struck with a hollow-faced iron hammer, the cavity being about an inch in depth and as much in diameter.

There is but little to boast of at Bombay in architecture in any way: in the Deccan the most massy structures are raised, and carved from trap, with a delicacy and correctness quite astonishing. The vaults and domes of tombs and temples are commonly bolted with iron from top to bottom, and in many cases, instead of scaffolding, the structure is surrounded with a rough wall ten or twenty feet off, the interval between being filled up with earth: a long inclined plane serves for raising the stones. A magnificent structure of this sort, the tomb of one of the Gwalior princes, has stood half finished near Poona for some thirty years; and here native architecture may be seen in perfection in all stages of advancement. The only building materials at the Bombay presidency, beside that already described, consist of greenstone, trap, and a fine grained variety of nummulite like Bath oolite,—called, from the name of the place whence it comes, Porebunder stone.

## ARTS AND MANUFACTURES.

(158) *Lapidary Operations.*—We now come, by natural transition, from stone-cutting on a large to that on a small scale—from the operations of the architect to those of the lapidary. And here we must begin with an account of the gems most abundant and familiar—the agates, onyxes, cornelians, and bloodstones, of the Raj-Peepla range, and Cambay cornelians as they are called from the place where they are mostly cut, and from which they are almost wholly brought to Bombay.

The cornelian in the Raj Peepla range is found in a bed of blue clay—the detritus, probably, of the adjoining rocks. Shafts are pierced in this to the depth of from thirty to thirty-five feet, and horizontal galleries run in any direction that suits the fancy of the miner: they are distributed promiscuously, and do not appear to lie in veins or loads. The galleries seldom exceed a hundred yards in length,—they often run into those of other mines: they are generally five feet in height, and four across. To each mine there are thirteen men attached—they work by turns. Each man must send up so many basketful of earth and stones before he is relieved. The stones are collected in baskets and drawn up by a rope run over roller or pulley. A group of people await them at the mouth of the shaft, and examine them one after another by chipping each on a piece of stone: the compact and fine-grained are the best, and the blacker the hue is at first the redder it becomes after being burnt. There were in 1832 about one thousand miners employed; and each man carried home with him a basket of stones every evening. They were spread out on the ground, and for a whole year turned over every four or five days to the sun: the longer they are exposed the richer become their tints. In the month of May they are burnt. The operation is effected by placing the stones in black earthen pots or chatties. The pots are placed mouth under, a hole being pierced in the bottom of each; over this is put a piece of broken pot. The pots are arranged in single rows: sheep's dung is the only fuel found to answer: the fire is always lighted at sunset and allowed to burn till sunrise. If any white spots appear on the surface of the pot, the burning is reckoned incomplete, and the fire, continued some time longer. On being removed the stones that have flaws are thrown aside as useless: those not sufficiently burnt are kept for next year's burning, and the remainder are sold for exportation.

Nearly the whole of the stones are cut at Cambay—the greater part of them are made into beads. The following is the process: the stones are first broken up into pieces of suitable size for the end they are desired to serve. An iron spike is stuck into the ground, point upwards: the stone is placed on this and chipped with a hammer till nearly rounded: it is then passed on to the

## ARTS AND MANUFACTURES.

polisher, who seizes it in a pair of wooden clamps and rubs it against a piece of sandstone placed in an inclined plane before him, turning it round from time to time till it assumes a globular form. It is then passed on to the borer and polisher: a hole is drilled in it with diamond dust, and the beads are finally polished by being put in a bag with some fine emery and rubbed against each other. Thus far on Cambay stones we have mainly abridged from an excellent Paper by Captain Fulljames, in the *Transactions* of the Bombay Geographical Society for 1839. The stones for other uses are sawn or ground down: and this brings us to the native lapidary's tools, which are simple and efficient to a degree. The wheel consists of a strong wooden platform sixteen inches by six, and three inches thick. In this are two strong wooden uprights. Between these is a wooden roller eight inches long and three in diameter, fastened into a head at the one end. This works on an iron spindle or axle at each end. On the one end the axle is screwed and fitted with a nut, by which the saw or grinding wheel can be made fast. The saw consists of a thin plate of iron,—the cutting material consisting of native emery or ground corundum—*koorund* as it is called. The lap wheels consist of two circular discs or cakes of lac with ground *koorund*, coarse or fine according to the work—of a copper disc for polishing, and a wooden one for finishing the work. These are spun backwards and forwards by a bow, the string of which passes round the roller. The lapidary sits on his hams, steadying the wheel with his foot and holding on the stone with his left hand while he works the bow with his right. For very fine work a small sized wheel similar to the English lapidary's wheel, but of smaller size, is used. It is driven by a multiplying wheel, strap and pulley.

The following from the Custom house returns, gives the value of the traffic in Cambay stones, which average betwixt £10,000 and £12,000 annually,—one per cent of the stones finding their way to Europe.

The chief articles into which they are wrought are paper-weights, knife-handles, miniature-sized cups and saucers, tablets for snuff-boxes, sets of brooches, necklaces, and bracelets, pins, buttons, and studs. A field gun, with all its appointments, is one of the finest ornamental pieces of Cambay stone work—they sell for from Rs. 40 to Rs. 50. The polish of Cambay stones is not such as pleases the eye of the English lapidary—yet were they sent home in their roughly finished state, they are so cheap that they might be expected to become a considerable article of commerce. They might be built up into mosaics for work tables, into chess-boards, and other elegant articles of furniture—the chief part of the work being performed here, where labour is cheap, the final finish being given at home. The Cambay agates equal the finest “Scottish Pebbles” in beauty; they generally exceed them in size, and may be had for a mere fraction of the price.

(159) *Shark-fishing at Kurrachee.*—There are twelve large boats, with crews of twelve men each, constantly employed in the Shark-fishery at Kurrachee. The value of the fins sent to Bombay varies from Rs. 13,000 to Rs. 18,000 a year. Of this a portion only passes directly into the hands of the fishermen, each boat earning perhaps Rs. 1000 annually, or Rs. 100 for each man. From this falls to be deducted the cost of material and other charges. Shark-fins sell in China at about \$32 per picul, or £6 per cwt. In the market of Macassar the ordinary price is from \$15 to \$16, or from £2-10s. to £3 per cwt. It is a singular fact, that this curious branch of trade, which was noticed by Dr. Royle (on the Production of Isinglass.—London, 1842,) in 1842, should, as stated by that gentleman, afford on some occasions to Bombay alone as much as four lacs of rupees—£40,000—taking fish-maws and shark-fins together,—and furnish the chief means of support to at least three thousand fishermen or, including their families, to probably not less than fifteen thousand human beings. One boat will sometimes capture at a draught as many as a hundred sharks of different sizes: sometimes they will be a week, sometimes a month, with-

out securing a single fish. The fishermen are very averse to revealing the amount of their captures: enquiries of this sort are supposed by them to be made exclusively for the purpose of taxation. The great basking shark, or mhor, is always harpooned: it is found floating or asleep near the surface of the water, and is then struck with a harpoon eight feet long. The fish once struck is allowed to run till tired, and is then pulled in and beat with clubs till stunned. A large hook is now hooked into its eyes or nostrils, or wherever it can be got most easily attached,—and by this the shark is towed inshore: several boats are requisite for towing. The mhor is often forty, sometimes sixty, feet in length; the mouth is occasionally four feet wide. All other varieties of shark are caught in nets in something like the way in which herrings are caught at home. The net is made of strong English whipcord, the mesh about six inches: they are generally six feet wide, and from six to eight hundred fathoms, or from three quarters to nearly a mile, in length. On the one side are floats of wood, about four feet in length, at intervals of six feet; on the other, pieces of stone. The nets are sunk in deep water from eighty to one hundred and fifty feet, well out at sea: they are put in one day and taken out the next, so that they are down two or three times a week, according to the state of the weather and success of the fishing. The lesser sharks are occasionally found dead,—the larger ones much exhausted. On being taken home, the fins are cut off and dried on the sands in the sun: the flesh is cut up in long stripes and salted for food, and the liver is taken out and crushed down for oil. The head, backbone, and entrails, are left on the shore to rot, or thrown into the sea, where numberless little sharks are generally on the watch to eat up the remains of their kindred. The fishermen themselves are only concerned in the capture of the sharks: so soon as they are landed they are purchased by Banians, on whose account all the other operations are performed. The Banians collect them in large quantities, and transmit them to agents in Bombay, by whom they are sold for shipment to China. Not only are the fins of all the ordinary varieties of shark prepared for the market, but those also of the saw-fish, of the cat-fish, and of some varieties of ray or skate—the latter, indeed, merges almost insensibly into the form of the shark. The cat-fish, known here by the same name as at home, has a head very like that of its European congener, from which it differs in all other respects most remarkably. Its skin is of a tawny yellowish brown, shading from dark brown on the back to dirty yellow on the belly: it is beautifully covered all over with spots, of the shape and size of those of the leopard, similarly arranged. The value of sharks' fins annually exported from

## ARTS AND MANUFACTURES.

Bombay amounts to betwixt a lakh and a half and two lakhs of rupees : the largest fishery at any given port is probably that of Kurrachee, which affords nearly one-tenth of the whole, but the shark-fishery is conducted all along our coasts. The fishermen along these coasts are divided into four great castes, over each of which a head man or jumadar presides. 1, Wayttee ; 2, Sôn-kolie ; 3, Dôngur-kolie ; 4, Thankur-kolie. One great jumadar, or chief, rules supreme in the craft over all the fisher castes. Our principal informants at Kurrachee were a chief of one of the castes and his brother,—two of the finest men we ever saw. They were six feet three each, nearly of a height, powerfully made and muscular in proportion, but not overgrown : they had fine brown hands, long black hair and bushy eyebrows, with fine white teeth, and a singular openness of countenance and pleasingness of expression. They seemed greatly flattered by our enquiries, and most willing to give information on every point but one—that of the amount of sharks caught. They were quite delighted with the sketches made of their boats and implements.—*Bombay Monthly Times, from 11th to 24th May, 1850.*

We now return to the subject of Native Arts and Manufactures ; in our last we were obliged to omit the observations we had proposed to give continuously until the subject so far as we were able to deal with it was exhausted.

*Stone-Cutting.*—Before concluding the account of stone-cutting, we must give a short notice of the seal-engraver's tools and wheel. The latter consists of a slight framé ballasted below to keep it firm, with two uprights about eighteen inches in length and eight inches between. Betwixt the two is a small spindle, of the form represented in the adjoining cut. This turns at the one end on a screw or pivot, sometimes of cornelian : the shoulder is kept in its place by a neat iron clamp—it is steadied by a piece of rag wrapped round it and enclosed in the collar. Why so much pains should be taken to diminish friction by a cornelian pin at one end, while it was increased by this at the other, we cannot explain. A dozen or two spindles such as this are made use of. The spindle is terminated by a small spike of iron about an inch long, ending in a little circular saw or button, from a tenth up to half an inch in diameter. To this, emery paste—that is, powdered corundum mixed with oil—is from time to time applied, while it is spun round with a bow. The engraver holds the seal up betwixt his fingers and thumb, and a sweep or two of the bow causes a mark on the seal. This is deepened and extended as desired—the larger discs being employed for long straight strokes. The work turned out is by no means very fine, but the celebrity of execution is surpassing. Diamond dust is

## ARTS AND MANUFACTURES.

very rarely used in India,—corundum, koorund, or sanda stone as it is called, being the chief material employed in polishing gems, marbles, and metals. This mineral is found chiefly in granite or the detritus of granite rocks in the Mysore country and in the neighbourhood of the south-western ghauts. It is brought in considerable quantity to Bombay, and is occasionally exported to Europe. It is packed in orange-shaped parcels with meridional cordings : the pieces are from the size of filberts to that of the hand : they are generally amorphous or fragments of crystals, often contaminated with felspar, mica, and other granitic minerals. Sometimes fragments of crystals perfectly pure are to be met with weighing from ten to twenty-five pounds, but these are rare. Though excessively hard, it is by no means tough—it flies in pieces after a few strokes of the hammer, and is easily pulverized in a mortar. The natives generally beat it on an anvil or stone, keeping it from flying about by a collar of cotton rope. The fine particles are separated from the coarse by sifting—we are not aware that the home process of lixiviation is resorted to. For sharpening swords or burnishing metal it is generally used like a whetstone or burnisher ; for polishing gems, it is either made up into a cake with lac or into a paste with oil or grease. It is never employed for the manufacture of emery paper, or anything resembling it. For polishing marble or other stone it is used in two forms : the first of these is a cake of about eight inches long, three across, and two deep, of this form. This is used by an individual in the hand. For heavier purposes, a cake a foot square or so is employed, placed in a frame after this fashion. Two men work at this, and the reducing process is very rapidly accomplished by it : it is in fact a file with a lac body and corundum teeth. This concludes our sketch of lapidary operations : we are aware of its being in the last degree imperfect and shall be thankful to any one who will fill it up, correct, or extend it. We have not been able to discover a single syllable on the subject in any printed book. The diamonds seen in such abundance amongst our native gentry are almost all cut in England, and our principal gems here are the lapis lazuli, rubies, emeralds, opals, garnets, and the whole family of siliceous gems.

(160) *Bombay or Mooltan Work.*—The inlaid work of ivory, white and dyed, ebony or other coloured woods, for which Bombay has long been famous, is said to have been introduced from the Punjaub, and is still familiarly known as Mooltan work. It consists chiefly of paper-cutters, work-boxes, writing-desks, and other similar articles. The effect of a large mass of it is very poor—the pattern is too fine for being distinguishable, and it fills the eye with a general greyish tint : in

## ARTS AND MANUFACTURES.

articles which do not present more than a foot or two of surface, it is very pleasing. The ground of the inlaid pattern is generally scented cedar or sandalwood, the joinery exhibited in which is very indifferent. The inlaying material is prepared as follows: the wood or ivory is cut into slips of a lozenge or triangular section, as may be required—by a long thin-bladed fine-toothed saw. The tin is drawn through betwixt a pair of grooved rollers like those used for laminating or extending iron—they work together by teeth at the extremity: one or two draws through extends the metal into the length desired. The wires and splints are nearly all either lozenge-shaped or triangular, the triangles being equilateral, the lozenges composed of two equilateral triangles. A pattern being fixed on, the splints are built up into pieces, about eighteen inches long, and from a quarter to two inches in thickness, firmly glued together. In the case of boarders, or continuous pieces of work, the rods are glued together betwixt pieces of ivory, or wood and ivory, alternately, so as to form straight lines on each side of the pattern. When about to be used they are sawn across the thickness of a sixpence, and arranged in a box divided into compartments, something like a printer's case. They are then picked up in succession, and applied with glue to the box or other article to be inlaid. The following is a list of the prices of some of the most common articles to be met with in the bazar:—

Work Boxes, of sizes, from.....	Rs. 8 to 80
Writing Desks, of do, from.....	Rs. 15 to 60
Portfolios, of do, from.....	Rs. 10 to 20
Watch Stands, from.....	Rs. 8 to 10
Do. Cases, from.....	Rs. 4 to 6
Envelope Cases, from.....	Rs. 15 to 25
Baskets, of sizes, from.....	Rs. 6 to 25
Cheroot Cases, from.....	Rs. 3 to 4
Card Cases, of sizes, from.....	Rs. 2 to 5
Paper Weights, from.....	Rs. 3 to 4
Paper Cutters, from.....	Rs. 1 to 3
Baskets, open work, from.....	Rs. 12 to 15
Table Trays, from.....	Rs. 10 to 15
Pin Cushions, from.....	Rs. 3 to 4
Ink Stands, from.....	Rs. 10 to 15
Jewel Boxes, of Sandal Wood, from.....	Rs. 20 to 50
Paper Stands, of Sandal Wood, from.....	Rs. 5 to 10

(161) *Blackwood Furniture.*—We are so imperfectly acquainted with the history of the Bombay Furniture manufacture that we must confine ourselves to a few details of the process by which it is made. Blackwood is the material almost always employed—it is brought from Cochin and other places lower down on the Malabar Coast. It sells for about the same price as Teak—it is a brittle, open-grained wood not at all a favorite with cabinet-makers at home, and the highest prices ever realised for it in the state of log were we believe about £10 per ton. The principal furniture dealers in Bombay, when this was written in 1850, were Par-

## ARTS AND MANUFACTURES.

Goozerat. The pattern meant to be carved is first carefully drawn on paper—then on the wood. The tools used are the native adze, chisel, and drill—the centre-bit and other tools of English pattern, from which so much assistance might be obtained, are never resorted to. The general design of the various pieces of furniture is mostly excellent, the patterns elegant and tasteful: the finish for the most part is poor,—the joinery always execrable. Concealed joints never seem to be thought of—pins which might be kept out of view are made as conspicuous as possible, and great clumsy screw nails, which might without trouble be hid, are fully exposed to view. Considerable quantities of blackwood furniture are sent home annually by residents in Bombay for their own after use, or for the service of friends: it is packed up without being jointed or polished, and is put together by English workmen, who think, we believe, but lightly of its merits. There were then six principal furniture shops in Bombay,—those of Messrs. Sorabjee Framjee, Sapoorejee, Byramjee, Pestonjee Eduljee, Rustomjee Nowrojee, Jamsetjee Limjee, and Manockjee Nowrojee. They keep from five to ten workmen each, and probably turn out Rs. 25,000 to Rs. 30,000 worth of furniture amongst them annually. The following are the prices of the principal articles manufactured:—

Round Table, from 3 to 8 feet in diameter...	Rs. 30 to 80
Do. Teapots, 2 feet ditto, per pair.....	Rs. 16 to 25
Card Tables,..... do.....	Rs. 50 to 60
Flower Stands..... do.....	Rs. 50 to 100
Pier Tables..... do.....	Rs. 100 to 150
Conversation Sofas..... do.....	Rs. 100 to 150
Sofa Couches..... do.....	Rs. 140 to 200
Music Book Cases..... do.....	Rs. 80 to 140
Easy Chairs, each.....	Rs. 10 to 50
Low Chairs, each.....	Rs. 25 to 50
Drawing Room Chairs, with damask cushions.....	Rs. 5 to 10
Dressing Tables, each.....	Rs. 8 to 75
Side Boards, each.....	Rs. 35 to 70
Screens, each.....	Rs. 20 to 75
Wardrobes, each.....	Rs. 45 to 75
Clothes Presses, each.....	Rs. 25 to 40
Bedsteads, each.....	Rs. 50 to 200
Writing Tables, each.....	Rs. 50 to 100
Bed Room Couches, per pair.....	Rs. 40 to 60
Chiffoniers, each.....	Rs. 60 to 80
Sofa Tables, per pair.....	Rs. 60 to 90
Dining Table, in pieces.....	Rs. 40 to 50
Chests of Drawers, each.....	Rs. 25 to 50
Music Stands, per pair.....	Rs. 30 to 50

*Oil Manufacture.*—Fish oils are the only animal oils we possess in India—the manufacture of these we have already endeavoured to describe. The number of vegetable oils we possess is very great indeed—we must, however, confine ourselves to a notice of the manufacture of a small number of these. We are acquainted with two forms only of the native oil-mill: one of these will be found described under Sugar-making, it being used alternately as an oil or sugar-mill—the other, of which there are some varieties, is a simple wooden mortar, with revolving

## ARTS AND MANUFACTURES.

Francis Buchanan's description of the oil-mill of Bangalore: it closely resembles the model of that of Belgaum, lately sent to the presidency, only that the latter is of wood, the former of stone—generally granite. Two oxen are harnessed to the gearing which depends from the extremity of the pestle—a man sits on the top of the mortar, and throws in the seed that may have got displaced. The mill grinds twice a day,—a fresh man and team being employed on each occasion. When sesamum oil is to be made, about seventy seers measure, or two and a half bushels, of seeds are thrown in: to this ten seers, or two quarts and three quarters, of water are gradually added: this, on the continuance of the grinding, which lasts in all six hours, unites with the fibrous portion of the seed, and forms a cake, which, when removed, leaves the oil clean and pure at the bottom of the mortar. From this it is taken out by a coconut shell cup on the pestle being withdrawn. Other seed oils are described by Buchanan as made almost entirely in the same way as the sesamum. The exceptions are the larula, or castor oil, made from either the small or large varieties of the ricinus. This at Seringapatam is first parched in pots containing something more than a seer each. It is then beaten in a mortar and formed into balls: of these from four to sixteen seers are put in an earthen-ware pot, and boiled with an equal quantity of water for the space of five hours—frequent care being taken to stir the mixture to prevent it from burning. The oil now floats on the surface, and is skimmed off pure.

The oil-mill made use of at Bombay and to the northward, at Surat, Cambay, Kurrachee, &c., differs a little from that just described, in having a very strong wooden frame round the mouth of the mortar: on this the man who keeps the seeds in order sits: in Scinde a camel is employed to drive the mill instead of bullocks. Castor oil seed is thrown into the mill like other seeds, as already described:—when removed it requires to be boiled for an hour, and then strained through a cloth to free it of the fragments of the seed. The great oil on the seaboard of India is that yielded by the Coconut Palm. The nut is first stripped of its husk, this furnishing the substance from which coir rope is made, while the shell is broken, and the copra, or fatty lining, enclosing the milk is taken out. This is called cobi or copra. Three maunds or ninety pounds of copra are thrown into the mill, with about three gallons (eleven cutcha seers) of water, and from this is produced three maunds, or seven gallons and three quarters, of oil. The copra in its unprepared state is sold slightly dried in the market: it is burned in iron cribs or grates on the top of poles as torches in processions, and as means of illumination for work performed in the open air

## ARTS AND MANUFACTURES.

at night. No press or other contrivance is made use of in India for squeezing out or expressing the oil from the cake, and a large amount of waste in consequence of this necessarily ensues. We are unable to afford a description of the manufacture of the sandalwood, grass, and other essential oils employed in medicine.

*Tanning*—Leather is one of the manufactures where, with an unbounded quantity of excellent raw material, the results are most unsatisfactory: with an unlimited supply of hides and first-rate bark, the goods turned out are of the worst possible description. The raw hides on first being received are steeped in stone vats for betwixt four and five weeks in a strong pickle of salt and water—from ten to fifteen hides are placed in each vat. While steeping, a pint or quart of the milk bush is thrown into each vat. As we may not have occasion to allude to this subject under a separate head, we may mention that the juice of the milk bush (*Euphorbia tirucalli*—Roxburgh, page 470, Graham, page 179) contains a considerable quantity of elastic gum, and is used for water-proofing leather, and rendering cords elastic. In February and March, Parsee females are to be seen with various male attendants wherever the milk-bush prevails. They apply the milk to their bodies and limbs, and then stick themselves over with tufts of raw cotton. It produces a hot and slightly prickly feeling and a small degree of blistering. It is considered good for the health, and is supposed to ensure fecundity: the exhibitions seen at this season in applying the milk, are often indelicate in the extreme. Dr Heyne (Tracts, Historical and Statistical, on India, &c., vol. 1, page 46, London 1814) states that the Morocco manufactured at Hurryhur is treated with salt, and a mixture of water, and the milk of wild cotton, (*Asclepias gigantea*), but though he favours us with a chapter on the milk of plants, he neither explains its qualities nor the function it performs in tanning. The stench arising from the vats is at this time abominable: the epidermis is now decomposed, and the hair comes freely away. The skin, being cleared of this, is next immersed in a decoction of mangrove, babool, or other tanning bark: after remaining some time in this they are taken out and sewed up so as to form a sack, and are then suspended from the roof of the building, filled with fresh tanning solution. When the process is completed they are taken down, the stitches cut, and the skins dried. The leather is soft and flexible, and looks tolerably well—but it resists the rain indifferently, is easily penetrated by wet, and during the S. W. Monsoon becomes as moist and flexible as paper dipped in water. When set aside it becomes mouldy, and very easily rots. Buchanan gives the following as the method of tanning practised

at Bangalore:—For each hide of ox or buffalo take two seers of quicklime and six seers of water: in this keep the skins a week, when the hair may be rubbed off. Keep the hides four days in a solution of unpeeled sticks of Tangadu (*Cassia auriculata*), in ten seers of water, for an equal length of time: add the same solutions as before—then stretch and dry the hides. The leather is very bad. Tracts, Vol. 1., p. 228.

**Potstone**—Is found in various parts of India on the western coast: it is chiefly prevalent at Turreva Carey in the Madras presidency, and in the ghaut country from betwixt the Phoonda and Ram Ghauts. It is called Bellapum by the natives: it was known to the Romans, and is described by Pliny as used in the manufacture of vessels for culinary purposes—hence its name. The mineral possesses a glistening pearly lustre and greyish tint: it contains 49 per cent of silica, 30 of magnesia, and 6 of alumina. The stone is prepared for use by reducing it to something like the form, size, and shape desired, by a cleaver, a panned hammer, or strong knife. When a cavity is meant to be circular, it is bored out by being held against the working spindle of a single-centred native lathe. This enables them to be held on by the chuck, when they are chucked and finished in the lathe in the ordinary way. Potstone speedily hardens and darkens by exposure to the air: it absorbs grease, oil, or fatty matter, freely: it is stronger than ordinary earthen-ware, stands heat better, and is pretty extensively used for culinary purposes. That sold in the Bombay bazar is mostly brought from Goa.

(162) **Bombay Fisheries**.—We do not here propose attempting a description of the Bombay fishing boat—now allowed to be one of the swiftest and most elegant sea-going vessels we possess. A complete set of models of the native vessels plying on the coast, at an estimated price we believe of Rs. 15 each, or about Rs. 1000 in all, is in course of preparation for the Exhibition of 1851, and we can scarcely imagine anything more valuable or interesting. The mode of building is not a little singular, being, like most other processes, amongst us, precisely the reverse of that pursued at home. We begin with drawing the lines, then lay down the keel, ribs, and frame, and finally apply the planking. In India we dispense with drawn lines altogether:—having laid down the keel we fasten on the planking, leaving the ribs and frame to the last. The keel having been laid, and the stem and sternposts put in their places, they are fashioned in both sides with a groove of this form. The lower edge of the plank next laid is made to conform in shape to this. The under groove is smeared over with red ochre and water, and the edge of the plank that follows tried on from time to time till it takes a tinge everywhere, showing

with what exactness it coincides. It is then steeped in water and bent over a fire of wood into the proper shape and applied to its place. When all is ready, the channel in the lower plank is filled up with cotton and tar. The two planks are now sewed together in the following manner: a pair of holes are bored in the upper and a corresponding pair in the lower plank, all along at intervals of a foot or two, according to the nature of the lines: a strong coir string is laced through this in the form of the letter X, the knot being inside. A stout wedge of wood is next driven through the strings outside, so as to bring the planks perfectly in contact. The planks being put sufficiently in their places, when gunwale high is attained, the timbers are put in: when the planks have been nailed to them, the sewing holes are filled up either with nails when opposite a timber, or with wooden pins. The home reader may perhaps be informed that the Bombay fishing-boats beat the best of our English yachts: the masts rake forward instead of back—the keel is hollow in the middle and not so long as the stern-post, —the forepart of the boat sharp, with hollow lines, the stern plump and round. The following rude diagrams will give some imperfect idea of our meaning:—

\* \* \* \*

Hooks and lines are scarcely ever used on our shores,—nets of various forms and sizes being alone almost employed in catching fish. The most important and extensively practised variety is the stake-net fishing,—and stakes are often to be found thirty and forty miles out at sea—wherever, indeed, a bank within half a day's sail of land presents itself: the fishermen are quite enterprising enough to extend their operations to any distance, but there is no use in their going further off than they can return with their fish to the market fresh. The fishing stakes vary from 50 to 150 feet in length: they are built up in the following manner of successive pieces of wood,—the lower being frequently the long straight trunk of the coconut or palmyra tree. As many as five or six pieces of wood, from eight to ten inches in diameter, are used in the construction of a single stake. They are scarfed across each other, the scarfing being from three to five feet: the pieces are fastened together by strong rectangular fillets of wood of this fashion—Two or three boats are employed in towing the stake out to sea. Its point is made wedge-shaped—there is a hole near the point of the wedge, through which a rope is passed. The two ends of the rope are made fast to boats anchored at a considerable distance off: other boats now proceed and haul up the upper end of the stake till the point is found to descend by its own weight. When it has once caught hold of

## ARTS AND MANUFACTURES.

the mud the rope is released from its lower end, and the boats to which it was attached employed in steadying the top in the direction of the run of the tide. At high water two boats are made fast, one on each side, to the top of the stake, which is forced by their weight ten or twelve feet into the mud. Stakes are thus put in successively, often to the extent of some miles, at intervals of twenty feet from each other. Between each pair is extended a long purse-net, the circumference of the mouth of which is about sixty feet, so that when attached to the stakes it exhibits an aperture twenty feet across, and ten feet perpendicularly—the upper edge being a little above high water. The purse is from 100 to 170 feet in length, terminating in a point. The meshes gradually diminish in size from the mouth to the further extremity, being about six inches at the former, and three-fourths of an inch at the latter. The fish are carried into this by the tide, and entrapped—boats are always in waiting at high and low water, to secure the capture and reverse the nets. In the creeks and shoals lines of stakes and nets, often several miles in length, are run along where the sludge is exposed at low water. The upper edge of these is considerably under high water mark, and the fish are in consequence entrapped by them on the retirement of the tide: breaks are left at intervals to secure their admission. Close along shore, fishing grounds, about half an acre in area or so, and in a semi-circular form, are built. An aperture is left in the extremity of each of these, into which a net is placed as the tide begins to recede, and a considerable capture of the lesser sized fish secured. Such are the fixed implements of the fisherman: the moveable engines of destruction are few and simple. The most frequent of these is a conical net, of which the lower lip is loaded with pieces of lead and turned up inwards. The material of which it is made is fine, and the meshes small. It is from eight to twelve feet in diameter, and is only used in shore. The fisherman holds it by the top, while he gives it a quick twirl, something betwixt that given to the American lasso and common quoit. Throwing it to the distance of some yards, it spreads fully out as it reaches the water—when pulled down and collapsing by means of the lead, it closes at the mouth as it approaches the bottom. The fisherman now approaches and pulls it up by the apex, when the fish are found entrapped in it. Though this net sometimes attains a weight of sixty pounds—the dexterity with which it is thrown is wonderful. There are various spoon and purse-nets of different shapes and sizes, and a bag of muslin on a hoop about three feet in diameter, this last being employed to catch the young prawns, and smallest sized fish, that would escape through any mesh—however fine. There is

## ARTS AND MANUFACTURES.

also a long trail-net, with which the fishermen wade neck deep through the water, but the mode of using it does not appear to be in any way peculiar or interesting. The mud banks and shoals in our creeks abound in Eels, sometimes reaching the length of two or three feet. The fishermen wade through the mud till they detect these by the bubbling up or disturbance of the water. They then strike them with a harpoon or spear of the fashion here represented, and about two inches each way, with a fine bamboo shaft eight or ten feet in length. Having pinned them against the ground they draw them out with a hook about the same size as the spear, also on a shaft. They are very dexterous in catching the little fish or crabs which lurk under the stones close by the shore, with their hands without the use of any instruments at all: the crabs when caught are immediately stripped of their claws, and so prevented from getting away. Of these we have a wonderful variety on our shores, many of them of the greatest beauty. The fisherman's mooring anchor is generally of stone, from four to five feet in length, of the form represented in the adjoining drawing. The stone is four-sided and pyramidal—the apex cut off. At base it is from six to eight inches square, and from four to six at top. Through the top is a hole, through which a cable or hawser passes. Near the base are two holes at right angles to each other: through these pieces of wood are thrust corresponding to the prongs or flukes of the anchor. The whole weighs from 80 to 150 lbs., according to the size of the vessel, and answers very well the purposes intended. These anchors are most commonly made of limestone, and are on the whole most suitable.

The fishermen are a strong-made race of men, and the only variety of labourers in India amongst whom a great degree of obesity is observed,—every fourth or fifth fisherman to be met with being more or less corpulent—some of them very much so indeed. They are much given to the use of intoxicating drinks, and are often to be met with in a state of inebriety. They regulate their affairs very much after the manner in which they are regulated by those of kindred professions in other parts of the world. A set of boats and nets belong to a dozen of fishermen, one often advancing the capital required to be contributed by the others; the capture is divided amongst them on their reaching the shore, and is immediately taken charge of and carried to market by the women, who carry their baskets, not, as at home, on their backs, but on their heads. The men when so employed carry theirs in baskets swung at the opposite ends of a bamboo across the shoulders. The women who carry the fish to market are commonly followed by ten or a dozen crows, who constantly

## ARTS AND MANUFACTURES.

watch for anything that may escape, every now and then making a dash at the basket itself.

The mode of making ropes and nets is singularly simple: coir is the material used for the former, cotton or hemp for the latter. One man sits on the ground and lets out the yarn; another retires half bent, and spins it by means of a spindle,—the yarn being passed through a wooden hoop hung round his neck. He gives the spindle a jerk betwixt the palms of his hands, and keeps its motion up at a very considerable degree of speed indeed. When several piles of fine yarn are to be twisted together, a man with a spindle is placed at the end of each. The whole series are supported at intervals by frames of bamboo: a spinner at the further extremity twists all the strands into one, while a light piece of board is being passed along where the cords are meant to be hard plaited and strong, to keep them from running too rapidly together. In the case of ropes, after the single strands are laid together, the rope is made up by men twisting the larger strands by a stout piece of wood thus,—a much stronger and longer piece being used for the entire rope, a man sitting by a board with holes through which the several strands pass, to see that all go properly together. To see forty or fifty five powerful men busily employed in the evening in sewing a cord betwixt each of the cloths of a sail—the sails of a pattimar being often from seventy to ninety feet wide,—with the accompaniments of swarthy dames and children,—boats of the most picturesque forms,—palm trees or an old Mahratta fort in the distance, and fishing tackle every where around,—is frequently highly picturesque; the sight being much more pleasing than the smells which accompany the scene.

We are unable to give any account of the population of the fishing villages beyond our own immediate neighbourhood, the number or cost of the boats or implements employed by them, or value of their industry, though information on all these heads would be eminently interesting, and ought to be easily enough attainable. The following in reference to the three great fishing villages in our own little Island,—Worlee, Sewree, and Mahim,—will illustrate what is desired to be obtained. At WORLEE there is one pattimar, worth about Rs. 3000, employed in carrying cargo and in general business. There are 110 fishing-boats, worth about Rs. 350 each, and 45 canoes, worth from Rs. 40 to Rs. 60 each. At SEWREE there are five large boats, worth about Rs. 1000 each, employed in carrying bricks and tiles from Salsette to Bombay; one pattimar, worth about Rs. 3000, employed in general trade; 23 fishing-boats, worth about Rs. 350 each; and 50 canoes. There are, besides, some 20 middling-sized boats, used in the transport

## ARTS AND MANUFACTURES.

of chunam and of black sand from Bellapore for building and other purposes. At MAHIM and in the creek on to Sion there are 7 fishing-boats, 10 large chunam boats, 10 small, together with 25 canoes. The fishermen of Small Colaba own no more than 16 fishing-boats and 8 canoes. A pattimar employs from 15 to 20 men, a fishing-boat from 10 to 15, a canoe from 3 to 4. Canoes are chiefly employed in the coast-fishing and attending the men on the mud banks, and in landing cargo when there is not depth of water sufficient for larger vessels. They are hollowed out of a single log, and are very serviceable handsome-looking well-finished craft. They are impelled either by paddles or sails: when the latter are employed, an outrigger is resorted to: they will bear a surprising stretch of canvas, and make their way rapidly through the water.

*Distillation.*—The principal matters distilled in India are Toddy, Dates, Sugar, Rice, and substances yielding perfumes. As it is with the arts as practised on this side of India, we are chiefly concerned, we shall commence with the Bombay Toddy or Arrack Still, one of the most simple and clumsy contrivances that can well be imagined. The still consists of a large earthen jar, of the shape of that used by water-carriers, but many times more capacious. The receiver is of the same form and material as the still, but somewhat less in size,—the former being two and a half, the latter one and a half, feet in diameter. The still mouth is plugged up with a piece of wood luted with clay—a hole is cut in the side of the still near the top, and into this is fastened a wooden spout, which conveys the spirituous vapour to the cooler. This last stands on a tressle or frame of wood, placed over a pit for holding water, and cooling is effected by a man lifting successive fills of water from the well in a coconut ladle, and pouring it on the top of the cooler. We have seen no case where a contrivance so simple as a vessel of water with a small spout or drip has been resorted to. A coconut tree will yield about four seers of toddy or sap a day: seventy-five seers of toddy, or the produce for one day of eighteen coconut trees, furnish a charge for a still, yields twenty-five seers of liquor on a first distillation—on the second it affords eight seers of liquor considerably under proof. Loose as this mode is of stating matters, we have not been able to make it more exact: we know of no author who furnishes information as to the quantity of sugar contained in toddy, and the amount of spirit of a given strength it ought to yield, and have not had leisure to determine these facts for ourselves,—a sad instance of the want of familiarity with the principles and details of the most common branches of industry prevailing around us. One thing seems certain, that the process of distillation just described is nearly as unskilful as can

## ARTS AND MANUFACTURES.

be, and that a third, if not a half, might be added to the returns were a little more care and attention bestowed on the matter.

Date and Palmyra trees yield toddy as well as cocoanuts—we do not know in what quantity per tree, or of what strength.

A strong liquor, called Mowah, is in popular repute amongst the natives, especially the Parsees, in Western India. The following process is employed in making it at Surat—we have not seen any Mowah still at Bombay. The berries of the Mowah are about the size and form of marbles: they are first steeped or mashed in casks. So soon as they get into a state of active fermentation, the fermented liquor is drawn off and carried to the still, and more water poured over the berries, successive charges being added as long as the worts are strong enough to ferment. A sufficient number of casks, or mash tuns as they may be called, are employed in the work so as to permit a charge of the still to be supplied on each drawing off from the fermenting tuns: as it takes a couple of days to complete the process of fermentation, but worts already drawn off would sour were this to be waited for before that first run was run off. The still consists of a wooden tub, with a copper bottom, built over a furnace of brickwork:—over the mouth of this is placed a huge copper saucer, the centre of the bottom terminating in a nipple. This is placed over the mouth of the tub which contains the liquor, and is fitted tight after the still has been charged: it is then filled with cold water, a fresh supply of which is poured into it from time to time as the original fill gets heated. A bamboo spout passes through the side of the tub just above the level of the liquor inside—it terminates in a flat shovel or ladle shaped dish under the nipple. Into this the spirit condensed in the under side of the saucer trickles down—it is run off and removed into a suitable receptacle outside. A second or third distillation is resorted to when the liquor is required to be made very strong. We have still more grounds here than in the preceding case to complain of our deplorable want of facts—a want which might be so readily supplied by the medical or scientific officers in the neighbourhood.

The Portuguese use, for the purpose of rectification, is a very neat and serviceable variety of still, by them called an Alembic. It consists of a common looking pot as a boiler, with a cylindrical head of the same diameter, and generally about the same depth, as the boiler. The bottom of this is a cone closed in at the apex, the mouth of which covers that of the boiler. Around its inner edge is a slight turned-up ledging or flange, from which a pipe or worm leads off the spirit. The cylindrical portion of the top being filled with cold water, the spirituous

## ARTS AND MANUFACTURES.

vapour is condensed by it in the inside of the cone, and, trickling down, is caught by the flange and carried off by the pipe. This is a convenient and serviceable implement, and may be so used to give very excellent results.

Our account of distillation would be incomplete without some description of the manufacture of rosewater and otto of roses, borrowing from the 8th volume of the Transactions of the Bengal Asiatic Society, the account given of it by Dr. Jackson, Ghazee-pore:—

“Around the station of Ghazee-pore there are about 300 beegahs, or about 150 acres, of ground laid out in small detached fields as Rose gardens, most carefully protected on all sides by high mud walls and prickly pear fences, to keep out the cattle. These lands, which belong to Zemindars, are planted with Rose trees, and are annually let out at so much per beegah for the ground, and so much additional for the Rose plants—generally five rupees per beegah, and twenty-five rupees for the Rose trees, of which there are 1,000 in each beegah. The additional expense for cultivation would be about 8-8; so that for Rupees 20-8 you have for the season one beegah of 1,000 Rose trees.

“If the season is good this beegah of 1,000 Rose trees should yield one lac of Roses. Purchases for Roses are always made at so much per lac. The price of course varies according to the year, and will average from 40 to 70 Rupees. During the past season the latter was the price given for one lac of Roses towards the conclusion.

“As soon as the Roses come into flower the Zemindar and cultivators of the Rose gardens, as well as intending purchasers, meet in the city, and according to the demand and expected produce, a *nerick* is established, and purchasers then enter into agreement with the cultivators for so many lacs of Rupees at such a price. This agreement is considered binding, and the cultivator is obliged to deliver the quantity at the contract rate; when that is completed another can be made, but this latter is always at a much higher rate.

“The Rose trees come into flower at the beginning of March and continues so through April. In the morning early the flowers are plucked by numbers of men, women, and children, and are conveyed in large bags to the several contracting parties for distillation. The cultivators themselves very rarely manufacture.

“The native apparatus for distilling the Rosewater is of the simplest construction; it consists of a large copper or iron boiler well tinned, capable of holding from eight to twelve gallons, (shaped like the earthen hoondahs in which the Gomastahs send in their Opium) having a large body with a rather narrow neck, and a mouth about eight inches in diameter; on the top of this

## ARTS AND MANUFACTURES.

is fixed the head of the still, which is nothing more than an old *degchee*, or cooking vessel, with a hole in the centre to receive the tube or worm.

"This tube is composed of two pieces of bamboo, fastened at an acute angle, and it is covered the whole length with a strong binding of corded string, over which is a luting of earth to prevent the vapour from escaping. The small end, about two feet long, is fixed into the hole in the centre of the head, where it is well luted with flour and water. The lower arm or end of the tube is carried down into a long necked vessel or receiver, called a *bhubka*. This is placed in a hundee of water which as it gets hot is changed. The head of the still is luted on to the body, and the long arm of the tube in the *bhubka* is also well provided with a cushion of cloth, so as to keep in all vapour. The boiler is let into an earthen furnace, and the whole is ready for operation.

"There is such a variety of Rose-water manufactured in the bazar, and so much that bears the name, which is nothing more than a mixture of sandal oil, that it is impossible to lay down the plan which is adopted. The best Rose-water however in the bazar may be computed as bearing the proportion of one thousand Roses to a seer of water; this perhaps may be considered as the best procurable. From one thousand Roses most generally a seer and a half of Rose-water is distilled, and perhaps from this even the Attar has been removed.

"The boiler of the still will hold from eight to twelve or sixteen thousand Roses. On eight thousand Roses from ten to eleven seers of water will be placed, and eight seers of Rosewater will be distilled. This after distillation is placed in a carboy of glass, and is exposed to the sun for several days to become *puckah*; it is then stoppered with cotton, and has a covering of moist clay put over it; this becoming hard effectually prevents the scent from escaping. The price of this will be from twelve to sixteen rupees. This is the best that can be procured.

"To procure the Attar, the Roses are put into the still, and the water passes over gradually as in the Rose-water process; after the whole has come over, the Rosewater is placed in a large metal basin, which is covered with wetted muslin tied over to prevent insects or dust getting into it; this vessel is let into the ground about two feet, which has been previously wetted with water, and it is allowed to remain quiet during the whole night. The Attar is always made at the beginning of the season when the nights are cool; in the morning early the little film of Attar which is formed upon the surface of the Rosewater during the night is removed by means of a feather, and it is then carefully placed in a small phial; and day after day as the collection

## ARTS AND MANUFACTURES.

is made it is placed for a short period in the sun, and after a sufficient quantity has been procured it is poured off clear, and of the colour of amber, into small phials. Pure Attar when it has been removed only three or four days has a pale greenish hue, by keeping it loses this and in a few weeks' time it becomes of a pale yellow. The first few days distillation does not produce such fine Attar as comes off afterwards, in consequence of the dust or little particles of dirt in the still and the tube being mixed with it. This is readily separated from its sinking to the bottom of the Attar, which melts at a temperature of 84°. From one lac of Roses it is generally calculated that 180 grains, or one tolah, of Attar can be procured; more than this can be obtained if the Roses are full sized, and the nights cold to allow of the congelation. The Attar purchased in the bazar is generally adulterated, mixed with sandal oil or sweet oil; not even the richest native will give the price at which the purest Attar alone can be obtained, and the purest Attar that is made is sold only to Europeans. During the past year it has been selling from 80 to 90 rupees the tolah; the year before it might have been purchased for 50 rupees. Native stills are let out at so much per day or week, and it frequently occurs that the residents prepare some Rose-water for their own use as a present to their friends, to secure their being provided with that which is the best. The natives never remove the calices of the Rose flowers, but place the whole into the still as it comes from the gardens.

"The best plan appears to me to have this removed, as by this means the Rose water may be preserved a longer time, and is not spoiled by the acid smell occasionally met with in the native Rose-water. It is usual to calculate 100 bottles to one lac of Roses. The Rose-water should always be twice distilled; over ten thousand, Rosewater may be put to allow of sixteen or twenty bottles coming out; the following day these twenty bottles are placed over eight thousand more Roses, and about eighteen bottles of Rosewater are distilled. This may be considered the best to be met with. The Attar is so much lighter than the Rose-water, that previous to use it is better to expose the Rose-water to the sun for a few days, to allow of its being well mixed, and Rose-water that has been kept six months is always better than that which has recently been made.

"At the commencement of the Rose season, people from all parts come to make their purchases, and very large quantities are prepared and sold. There are about thirty-six places in the city of Ghazeepore where Rosewater is distilled. These people generally put a large quantity of sandal oil into the receiver, the oil is afterwards carefully removed and sold as sandal Attar,

and the water put into carboys and disposed of as Rose-water. At the time of sale a few drops of sandal oil are placed on the neck of the carboy to give it a fresh scent, and to many of the natives it appears perfectly immaterial whether the scent arises solely from the sandal oil or from the Roses; large quantities of sandal oil are every year brought up from the south and expended in this way.

"The chief use the natives appear to make of the Rose-water, or the Sandal Attar as they term it, is at the period of their festivals and weddings. It is then distributed largely to the guests as they arrive, and sprinkled in profusion in the apartments. A large quantity of Rose-water is sold at Benares, and many of the native Rajahs send over to Ghazee-pore for its purchase. Most of the Rose-water as soon as distilled is taken away, and after six months from the termination of the manufacture there are not more than four or five places where it is to be met with.

"I should consider that the value of the Roses sold for the manufacture of Rose-water may be estimated at 15,000 rupees a year, and from this to 20,000, and from the usual price asked for the Rose-water and for which it is sold, I should consider there is a profit of 40,000 rupees. The natives are very fond of using the Rose-water as medicine, or as a vehicle for other mixtures, and they consume a good deal of the petals for the conserve of Roses, or *Goolcond*, as they call it. There are several kinds of essential oils produced from the strong scented flowers in this district, which I will procure and send down to you."

Other perfumed oils are manufactured without resorting to distillation. The layers of the jasmine, four inches thick and two inches square, or other flowers, are laid on the ground and covered over with layers of sesamum or any other oil-yielding seed. These are laid about the same thickness as the flowers, over which a second layer of flowers like the first is placed. The seed is wetted with water, and the whole mass covered with a sheet held down at the end and sides by weights, and allowed to remain for eighteen hours in this form: it is now fit for the mill, unless the perfume is desired to be very strong, when the faded flowers are removed and fresh ones put in their place. The seed thus impregnated are ground in the usual way in the mill, and the oil expressed having the scent of the flower. At Ghazee-pore, the jasmine and bela are chiefly employed: the oil is kept in dubbers, and sold for about Rs. 2 a seer. The newest oils afford the finest perfumes. The process here described is the same as that pursued at Bombay. In Europe, a fixed oil, usually that of the bean or morunga nut, is employed. Cotton is soaked in this and laid over layers of flowers, the oil being squeezed out so soon as

impregnated with perfume.—*Monthly Bombay Times*, 25th Nov. to 24th June 1850.

(163) ATTA, Pounded-wheat: when sifted *Myda* is the finer part or wheaten flour; and *soojee* the coarser.

(164) ATTALEA FUNIFERA. PIACABA. A most valuable palm, found in the native forests of the maritime provinces of Brazil, the fibres of its leaf stalks and other parts furnishes the best Cordage of South America.

It is a coarse black fibre and obtained from the dilated base of the petioles. It is collected by the natives, and partly used for consumption, partly exported to Europe, tied up in bundles of several feet in length, and sold in London under this name at about £ 14 the ton. It is manufactured into cordage in its native countries, and as it is light, cables made of it do not sink in the water.—*Seeman*.

*Coquilla Nuts* are produced in South America, in the Brazils, by the *Attalea funifera*, according to Martius, for the *Cocos lapidea* of Gartner; the latter title is highly descriptive. The plant might advantageously be introduced into Southern Asia. The coquilla nut shell is nearly solid: two separate cavities, each containing a hard, flattened, greasy kernel, generally of a disagreeable flavour: the cells occasionally enclose a grub or chrysalis, which consumes the fruit. The passages leading into the chambers are lined with filaments or bristles, and this end of the shell terminates exteriorly in a covering of these bristles, which conceal the passages; this end is consequently almost useless, but the opposite is entirely solid and terminates in the pointed attachment of the stalk. Sometimes the shell contains three kernels, less frequently but one only, and one coquilla nut has been seen entirely solid. The substance of the shell is brittle, hard, close, and of a hazel brown, sometimes marked and dotted, but generally uniform. Under the action of sharp turning tools, it is very agreeable to turn, more so than the cocoa-nut shell; it may be eccentric turned, cut into excellent screws, and admits of an admirable polish and of being lathered. On the whole it is a very useful material, and suitable for a great variety of small ornamental works both turned and filed.—*Holzappel*. Seeman remarks that Coquilla nuts being excessively hard, beautifully mottled with dark and light brown, and capable of taking a very high polish, they are extensively used for turnery work, especially in making the handles of bellpulls, small tops, the knobs of walking sticks, umbrellas and other articles.—*Seeman*.

(165) ATTAR. A set of scented oils or attars from Hyderabad comprise the following.

Moteah	Uttur.	Kaserah	Uttur.
Chumbaley	"	Chumpah	"
Ryatree	"	Gool	"
Inah	"	Banjeree	"

# AVERRHOA BILIMBI.

Burmookce	Uttur.	Sohag	Uttur.
Droolpend	"	Sona Manthre	"
Cuscus	"	Nohrutten	"
Moleserree	"	Sandal	"
Rowseh	"	Muzinah	"

They vary in price from 4 annas to 5 Rs. per tola. A very complete collection of these oils was exhibited, at the Madras Exhibition of 1855, by W. E. Underwood, Esq. comprising,

Oil of Sandal wood.	Oil of Cuscus.
" Star Anise.	" Mint.
" Coriander.	" Nutmeg.
" Pepper.	" Cardamom.
" Bitter orange.	" Indian Southern-wood.
" Cummin.	" Jessamine.
" Screw Pine.	" Bishops weed.
" Cloves	" Sweet Fennel.
" Patchouli.	

(166) ATTEES,

Attees, HIND.

According to Ainslie, Attees is the Hindoo-stanic name of the bark of a species of Betula, used in the northern parts of India for dying Clintz red, and which is sometimes, though rarely, brought to the Coromandel coast.—*Ainslie's Mat. Med. p. 141.*

(167) ATTI NAR, FIGUS-RACEMOSA.

(168) AUNEN WOOD.

Aunenkura, TEL.

(169) AVERRHOA CARAMBOLA. CA-RAMBOLA.

Kamarunga, HIND. and BENG.

The carambola tree bears a sour fruit which makes a good tart, and there is a variety which bears a sweet fruit. The tree, though originally, it is said, from the Moluccas, flourishes well on the Tenasserim Coast, and is quite naturalized.—*Mason.*

*The Fruit.*

Tamartam pullum, TAM.	Carumbola, Carmaranga.
Kumruk, DUK.	SANS.
Tamarta pundoo, TEL.	

This is a five cornered fruit, rather bigger than a hen's egg: when young, it is made into pre-serve; when full grown, it has a pleasant flavor, and is reckoned cooling and aperient.—*Ainslie, page 233.*

The Kamarunga tree is common in Bengal. The five-cornered, green, and juicy fruit contains a large quantity of quadroxalate of potash. It is used as a pickle, in curries, and as an ingredient in several native electuaries. The dyers also employ it very extensively.—*O'Shaughnessy.*

(170) AVERRHOA BILIMBI, Lin. Bilim-bie, common in Bengal; the fruit resembles a small cucumber, and contains an abundant acid juice of similar properties to those of the pre-ceeding species. A syrup is prepared with the juice, and a conserve with the flowers, by the

# ASOKA. JONESIA ASOKA.

native physicians, who use it in the treatment of fevers.—*O'Shaughnessy, page 257.*

*The Fruit.*

Bilimbic pullum, TAM.	Blimbingbooloo, MALAY.
Belumboo, DUK.	Bessee, SUMATRAN.

This is a pleasant tasted but rather too acid fruit. It is commonly made into pickle or pre-serve.—*Ainslie, page 222.*

(171) AVICENNIA TOMENTOSA.

Binabe, BENG. | Pata, Rhede.

Is common in India in low places near the mouths of rivers where the spring tide rises. In the Soondrabund it grows to be a tree of considerable magnitude the wood of which serves the Natives for various economical purposes. On the Coromandel Coasts where it is common it is found in the state of a shrub.—*Rohde M.S.S.*

(172) ASCLEPIAS CURRASSAVICA, the yellow milk weed, is cultivated in China as a flowering plant.—*Williams' Mid. King: p. 288.*

(173) ASCLEPIAS VOLUBILIS. Lin.

Palay keeray, TAM.	Palay koora, TEL.
Nukhikae ke banjee, DUK.	<i>Ains. Mat. Med. p. 255.</i>

(174) ASHES.

Sambool, TAM.	Bhasnuam, SANS.
Boodida, TEL.	

Wood ashes are useful for cleaning metals; enclosed in a bag and dusted through it by striking it on a knife board, it is a good substitute for bath brick for cleaning knives. Balls of Cowdung ashes are sold in the bazars under the Teloogoo name of Vibudi, *Tamul*, Tiroonoot Oondi, and are much used for cleaning Military appointments and brass mountings of harness, &c. In commerce, the term applies to such vegetable ash as the alkaline salts are extracted from.—*Mr. Rhode, M.S.S.*

(175) ASHOORA, Arab. The first ten days of the month Mohurram, or the Ceremonies observed during that part of the month. Houses are appropriated in which they set up Allums, Taboots, Shahnusheens, Booraq's, &c., and sometimes screens made of mica. These places are called the Ashoor Khanah (ten day house); Tazee Khanah (the house of mourning); and Astana (a threshold or faqueer's residence). In Upper Hindustan opulent Mahomedans erect an Emambara, and the Shiahs generally follow a similar practice.—*Herklots.*

(176) ASOKA; JONESIA ASOKA. The Asoka, in spring, bears beautiful red blossoms. This tree says LadyFaukland (*Chow-Chow*), is sacred to Mahadeva, (Siva). In some places in India it is more esteemed than at others. The women bathe in some holy streams with the blossoms floating in it. The Hindoos say that the contact of the stem of the Asoka tree with the foot of a woman of superior beauty, is supposed to make it blossom. This tree is often alluded to

## ASPARAGUS ASCENDENS.

in Select Specimens of the Theatre of the Hindoos, translated by Mr. Wilson. In the 'Toy Cart,' Maitreya says, describing a garden— "And here the Asoka tree with its rich crimson blossom, shines like a young warrior bathed in the sanguine shower of the furious fight. Captain D. L. Richardson, however, (Flowers and Flower Gardens, p. 189), says that the flower is small and yellow, and is eaten by young Hindoo women as a medicine. Voigt says its flowers are of an olive yellow colour.

(177) ASPALATHUS INDICA. Lin.

Shevenar vaymboo, TAM. | Small flowered aspalathus, ENG.  
Shivanimba, SANS.

The small leaves, flowers and tender shoots of this low growing plant, are supposed by the Natives to possess cooling demulcent and alterative properties and are prescribed in decoction in leprous and cancerous affections.

This plant appears to be the Manneli of the Hortus Malabaricus. Rheede tells us, that from the root of it an oil is extracted which is of use in erysipelas.—*Ainslie's Mat. Med.* page 113.

(178) ASPHALT. Dr. Honigberger at p.p. 238 and 239, of his work, writing on the Asphaltum Persicum, Mumiai, Persian—says, that it is a certain specific in fractured bones, deserving the name of Osteocolla. It is a solid, hard, heavy, black, glistening mass without any particular odor. Only the genuine possesses the peculiar properties and is but seldom to be met with even in Persia itself, the place of its origin, for the king of Persia is reported to collect the whole product yearly and to inclose it in small silver boxes, which are distributed as presents to his family and friends. In all Eastern bazars may be found under the name of Persian Mumiai, a compound resembling the genuine in appearance. According to Dr. Seligmann, Mum in Persian, signifies wax, lai or Ajin is the name of the village in the vicinity of which the spring of water containing Mumiai or Mumiajin is found. The Mumiai was discovered in the time of Feridun. He also says that the *Asphaltum Selajit*, *Asphaltum Punjabinum* or Punjab Asphalt, is an officinal article at Lahore, brought from the hills. The Hakims and Hindoo doctors use it instead of the Persian Mumiai in cases occurring from exterior violence.

(179) ASPARAGUS ASCENDENS. Dr. Honigberger, p. 237, says that this product of Hindostan is used only by the natives, who, call it Setaver, or, Sittavair? The stalks, he procured at the bazar at Lahore, were as long as a finger, and as thick as a quill, rather spiral and longitudinally indented, of a horny yellow semi-transparent appearance, of a mucilaginous, sweet and astringent taste. He adds that it is worthy of remark, that the Tamool name of the Pavonia Zeylandica, Sittamoolie or Sittavayr, borders very closely on Sittavair or Setaver.

## ASTRONOMY.

(180) ASPARAGUS. HALLOON. Dr. Honigberger, p. 237, mentions that the seeds so called, are from the common Asparagus, which is cultivated in the North-West of Hindostan. The Hakims use them in debility of the stomach, in liver, spleen and renal disorders; they also attribute to them diuretic and aphrodisiac properties. They believe that the cultivated is more effective than the wild plant.

(181) ASPIDIUM BAROMETZ, the Tartarian lamb, so enthusiastically described by Darwin in his Botanic Garden, has long been celebrated in China. It is partly an artificial production, the ingenuity of Chinese gardeners taking advantage of the natural habits of the plant to form it into a shape resembling a sheep or other object.—*William's Middle Kingdom*, p. 275.

There are several species of Aspidium known in India, the *A. splendens*, and *parasiticum*, described by Mr. Graham, and the *unitum* and *flagelliferum*, in Voigt's Catalogue; and Dr. Hooker mentions that both in Sikkim and Nepal the watery tubers of an *Aspidium* are abundantly eaten.

(182) ASSAFÆTIDA. FERULA ASSAFÆTIDA, Lin. NARTHEX ASSAFÆTIDA, Falconer.

Perungayum, TAM. | Ingoova, TEL.  
Hing, DUK. | Hinga, SANS.

This is used by the Natives of India particularly the Brahmins who from living entirely on vegetable food and milk, require some powerful corrector of acescency, and find nothing that answers the purpose so well as this which is besides cardiac and antispasmodic, and so strongly are they impressed with an idea of its virtues that they think they would die without it.—*Ainslie's Mat. Med.* page 267.

(183) ASSAI, a beverage of Brazil prepared from the *Euterpe edulis*, Mart: a palm which might advantageously be introduced into India.

(184) ASSAMI. An individual a non-proprietor.

(185) ASSAYING, is a branch of chemical analysis, the object of which is to determine the quantity of gold or silver in any mixture with the baser metals.

(186) ASTA, or Patoo, a bast in use in Bheerbhoom.—*Royle Fib. Pl.*

(187) ASTER CHINENSIS. CHINESE STAR FLOWER.

This is very common in Ajmere gardens.—*Genl. Med. Top.* page 206.

It is the *Callistephus chinensis* of DeCandolle. Several species of Aster, however are named by Voigt as having been grown near Calcutta.

(188) ASTRONOMY. The divisions of time, such as they are presented in the Calendar, are composed of days, weeks, months, and years. The modes of determining these divisions, have been various among the nations of antiquity, and

there are still variations in these modes in the modern world.

The manner of reckoning the days by the ancient Jews, and which subsists amongst that people at the present time, is, to commence the day at a certain hour of the evening, and to finish it on the next evening at the same hour. Thus their sabbath begins on the afternoon of Friday, and is completed on the afternoon of Saturday. The Roman Catholic church also commences its festivals in the evening; and this custom is retained amongst ourselves in some of our popular observances, such as the eve of St John, and Christmas eve.

The civil day now commences at 12 o'clock at midnight, and lasts till the same hour of the following night. The civil day is distinguished from the astronomical day, which begins at noon, and is counted up to 24 hours, terminating at the succeeding noon. This mode of reckoning the day, is that used in the Nautical Almanac, and it sometimes leads to mistakes with persons not familiar with this manner of computation: a little consideration will obviate the difficulty. Thus January 10, fifteen hours, in astronomical time, is January 11, 3 in the morning civil time. In France and most of the states of Europe, as with us, the hours are counted up to 12, from midnight till noon, and from noon till midnight. In parts of Italy, and of Germany, the day is held to commence about sunset, and the hours are counted on till the next sunset. This mode is very inconvenient to travellers, as the noon of the "Italian hours" at the summer solstice is 16 o'clock, and 19 o'clock at the winter solstice.

The division of the day among *Mahomedans* is chiefly subservient to the stated times of performing their devotions, and is not generally very accurate. They begin their account at sunset, reckoning twelve hours from thence to sunrise, whether the night be long or short; from sunrise to sunset they also reckon twelve hours, and consequently a night hour is longer in the winter than an hour of the day, and in summer the hours of the day are longer than those of the night. At the equinoxes alone, all the hours are of equal length, and then they coincide with those adopted by us, in commencement and duration, differing, of course, 6 hours in enumeration, so that our six o'clock is their twelve, our seven is their one, &c. At other periods of the year, also, their six o'clock coincides with our twelve, but every other hour differs more or less from ours. The time of sunrise, and, consequently, the length of the day, being known, the length of each hour will be easily found by division, and the period of any given hour determined. Thus, if the sun rise at 7 o'clock, the length of the day will be ten hours (of 60 minutes each) and that of each hour 50 minutes. One o'clock, Mahomedan reckoning, will then

be at 50 minutes after 7, two o'clock 40 minutes after eight, and three o'clock will be half past nine, and so on of the others. When the sun rises at 5 o'clock the three first hours of the day will be completed severally at 10 minutes after six, twenty minutes after seven, and half past eight. In every case six o'clock arrives exactly at midday, which in India is called "*do pahar*, or the *second watch*."

The *Chinese* division of the day is as simple as our own, and not much unlike it. The Chinese begin the day an hour before midnight, and divide the twenty four hours into twelve parts of two hours each. Instead of numbering their hours as we do, they give a different name to each period of two hours; the names and corresponding time, according to our mode, are as follows:—

Tsze..... 11 to 1	Morning.	Woo..... 11 to 1	Afternoon.
Chow... 1 to 3	"	We... .. 1 to 3	"
Yin..... 3 to 5	"	Shin..... 3 to 5	"
Maou .. 5 to 7	"	Yew..... 5 to 7	"
Shin..... 7 to 9	"	Seo..... 7 to 9	"
Sze..... 9 to 11	"	Hae..... 9 to 11	"

The word Keaou is added when the hour of each period is intended, and Ching for the last. Thus, Keaou tsze is 11 at night, and Ching tsze 12 at night; Keaou Chow 1 in the morning, Ching Chow 2 &c. &c. The word K'hieh "quarter," is used after the hour with the numerals yih 1, urh 2, or sau 3, to subdivide the hours into quarters, which is the smallest division commonly employed: example, ching maou yih k'hieh a quarter past 6; keaou woo urh k'hieh, half past 11.

The *Hindoos* and the *Mahomedans* in India, divide the day into four watches, and the night into the same number; the day being considered to extend from sunrise to sunset. The watches are again divided into *ghurees*, which are 24 minutes each in length. As in the summer the days are longer than the nights, each day watch will then be longer than any watch of the night, though, from the necessity of each watch comprising an exact number of ghurees, there will generally be the difference of 1 ghurce between two watches of the same day. There is much variation in this respect, and although, in the latitude of India, the difference is not so great as it would be in a country more towards the north, it is still so inconvenient that the natives of India rarely understand their own method of dividing the day, and readily adopt the English mode.

In order to explain the mode of subdividing the watches, we shall detail the correspondence of ghurees with our hours in March and September, when the days and nights are equal, and when, in consequence, more regularity may be expected than at other seasons. It must be remembered that a ghurce contains 24 minutes, and that 60 ghurees make up the 24 hours; 30 ghurees, therefore, make up the time between

sunrise and sunset at this season. If these 30 ghurees were equally divided between the four watches, giving 7 ghurees and a half to each watch, their correspondence with our hours would be easily made; but as the Hindoo practice is never to divide a ghuree between two watches, but to continue every watch until the last ghuree is completed (with one exception) the watches will be of unequal length: the first and last watches will be of 8 ghurees, and the second and third of 7 ghurees each.

At 6 o'clock, the first ghuree begins with the rising sun and is completed at 24 minutes after 6; the second ghuree strikes at 48 minutes after 6, the third at 12 minutes after 7, and so on in succession until the end of the first watch, at 12 minutes after 9. At 36 minutes after 9, one ghuree strikes again, and the same detail continues until midday, when the second watch ends. The third watch ends at 48 minutes after 2, and the fourth at 6 o'clock, or sunset. The same succession continues during the night.

In the summer, when the sun rises about 12 minutes after five, and sets at 48 after 6, the day is 34 ghurees in length, and the night only 26. In this case the first watch of the day contains 9 ghurees, the second and third 8 each, and the fourth nine. In the night the four watches will contain, respectively 7, 6, 6, and 7 ghurees. In winter, of course the contrary arrangement takes place, the day consisting of 26 ghurees, and the night 34; circumstances being the same in other respects. In the intermediate seasons the watches will contain 6, 7, 8, or 9 ghurees each, according to the length of the day; arranging them so that each watch may contain an equal number of ghurees, if possible; if there be one ghuree in excess, it is to be added to the first watch; if two, to the first and last; and if three, to the first, second, and last. The last ghuree of the day will occasionally be lengthened or shortened, in order to finish the day with sunset, and the last of the night altered in the same way, that the day may begin at sunrise.

With such a variable system as the above, it is evident that no clocks could be made to mark the time; but a mode of denoting time has been adopted by the Hindoos, which is not without ingenuity. They provide a thin metal cup, a clepsydra, through the bottom of which a small hole is drilled; this cup swims on the surface of a vessel of water, until the water, running gradually through the hole, fills the cup, which then sinks. The hole is made of such a size, that the water rising sinks it in 24 minutes. A sort of gong, or shallow bell metal pan, called a ghureeal, is hung up near the vessel, to be struck at the expiration of each ghuree, which is known by the sinking of the cup. A man, who is employed to watch

the sinking of the cup, and to strike on the bell, is called a ghureealee. For the complete establishment of a ghuree, six or eight servants are necessary, who keep watch in turns. Such an expense can, of course, be afforded only by the wealthy; but the sound of a gong is usually loud enough for a whole village, and serves the purpose of a church clock.

We shall explain the operations of the ghureealee through the twelve hours of an equinoctial day; and the process of striking throughout the year will be easily understood from this detail. At six o'clock in the morning, as soon as the sun appears on the horizon, a little cup is put on the surface of the water; when it sinks, which will be at 24 minutes after 6, the time is called, but not struck, 1 ghuree. This ghuree is considered sacred to the sovereign and his ghureealee alone, has the privilege of striking it; with this exception the first ghuree is passed in silence throughout Hindostan. At the second ghuree, two blows are struck; at the third three, and so to the end of the watch, when eight blows are struck for the eight ghuree of the watch: then eight to show that 8 ghurees of the day are passed; and after an interval of a second or two, one loud blow is struck to shew the end of the first watch. The same process is repeated to the end of the second watch, except that the first ghuree is not passed in silence; and that at the end of the watch, which consists of 7 ghurees, after striking the seven blows, fifteen more are sounded, to show that fifteen ghurees are elapsed from sunrise, and then two loud blows to show the end of the second watch. At the end of the third watch, seven blows are struck for the 7 ghurees of the watch, twenty-two for the ghurees of the day, and three loud strokes for the third watch. At sunset, after the eighth stroke for the eight ghurees, thirty are sounded to show that 30 ghurees are passed since sunrise, and four loud ones for the completion of the fourth watch. As the fourth watch is never struck until sunset, the last ghuree will increase with the lengthening days, until in April, it would be equal in length to two ghurees, and the whole watch would contain 9 ghurees. To avoid so long a watch, one ghuree is added to the second watch, which before contained only 7 ghurees, and the last watch is reduced to its former length. In May the day is one ghuree longer, and this addition is made to the third watch, which before contained only seven. The four watches are then of equal length. At the end of May, a ghuree is added to the first watch, and near midsummer another to the last watch. The day then consists of 34 ghurees, and the night of 26 only; and, as the days decrease, 1 ghuree is taken away at a time, in the same order as they were put on, until the shortest day, when the whole detail recommences.

Some variation will occasionally take place

in consequence of the difficulty of ascertaining the precise moment of sunrise, though much less in India than would be the case in a cloudy atmosphere. Change will also arise from the negligence or idleness of the ghurcealee; and tales are sometimes told of great men, for whose convenience the complaisant ghurcealees will add a ghurce to a watch, or accelerate the sinking of the little cup to accommodate their master's pleasure. These circumstances will prevent any exact coincidence of ghurees with hours practically, though there will be no great discrepancy by attending to the rules laid down above.

The English names of the days of the WEEK are derived from the Saxons; and they partly adopted these names from the more civilized nations of antiquity. The following ingenious origin of the ancient names has been suggested in connexion with astronomical science. The planetary arrangement of Ptolemy was thus:—1, Saturn; 2, Jupiter; 3, Mars; 4, the Sun; 5, Venus; 6, Mercury; 7, the Moon. Each of these planets was supposed to preside, successively, over each hour of the 24 of each day, in the order above given. In this way Saturn would preside over the first hour of the first day, Jupiter over the second hour, Mars over the third, the Sun over the fourth, and so on. Thus the Sun presiding over the fourth, eleventh, and eighteenth hours of the first day, would preside over the first hour of the second day, and carrying on the series, the Moon would preside over the first hour of the third day, Mars over the first hour of the fourth day, Mercury over the first hour of the fifth day, Jupiter over the first hour of the sixth day, and Venus over the first hour of the seventh day. Hence, the names of the days yet used in the learned professions throughout Europe. The present English names are derived from the Saxon:—

<i>Latin.</i>	<i>English.</i>	<i>Saxon.</i>
Dies Saturni	Saturday	Saterne's day.
Dies Solis	Sunday	Sun's day.
Dies Lune	Monday	Moon's day.
Dies Martis	Tuesday	Tiw's day.
Dies Mercurii	Wednesday	Woden's day.
Dies Jovis	Thursday	Thor's day.
Dies Veneris	Friday	Friya's day.

Tiw, Woden, Thor, and Friya were deities of the pagan Saxons. Thor was the god of thunder, as well as the ancient Jove, and Friya was a goddess, the wife of Woden.

Almost all nations have regulated their months, in a great degree, by the revolution of the moon. Some have endeavoured to unite this division with the annual course of the sun, by an augmentation of days at the end of each year, or by adding a thirteenth month at the end of every third year. The Jews and the Athenians followed this latter method; the Macedonians, and some nations of Asia, assigned their months 30 and 31 days; the Turks and the Arabs have 29 and 30

verned by the revolutions of the moon. Their common year consisted of twelve lunar months, three months being appropriated to each of the four seasons; but every third year contained an additional lunar month, which was given to the summer season. The names of their lunar months, either had reference to their religious ceremonies, or to the natural appearances of the year.

A considerable variation prevailed, generally, amongst the nations of antiquity, and still partially prevails, with regard to the commencement of the year. The Jews dated the beginning of the sacred year in the month of March; the Athenians in the month of June; the Macedonians on the 24th September; the Christians of Egypt and Ethiopia on the 29th or 30th of August, and the Persians and Armenians on the 11th of August. The Jewish civil year begins on the first day of the month Tisri, which year corresponds with our 9th of September; the Mahomedan's begins on the 1st of the month Moharem, which year, corresponds with our 14th of July. Nearly all the nations of the Christian world now, commence the year on the 1st of January; but as recently as 1752, even in England, the year did not legally and generally commence till the 25th of March. In Scotland, at that period, the year began on the 1st of January. The difference caused great practical inconveniences, and January and February, and part of March, sometimes bore two dates, as we often find in old records, as 1711-12. This practice often leads to chronological mistakes; for instance, we popularly say, "The Revolution of 1688," that great event happening in February of the year 1688, according to the then mode of computation; but if the year were held to begin, as it does now, on the 1st of January, it would be "The Revolution of 1689." In the anniversaries given in the Almanacs, the alterations of style made in 1752, are not followed, as any correction of dates would embarrass the reader in historical and biographical references.

The year, properly so called, is the solar year, or the period of time in which the sun passes through the twelve signs of the Zodiac. The period comprises 365 days, 5 hours, and 48 minutes, 51 seconds, 6 decimals, and is called the astronomical year.

The CALENDAR is a table of the days of the year, arranged to assist the distribution of time, and to indicate remarkable days connected with devotion or business. If every nation had adopted the same division of time, and an uniform calendar had been general throughout civilized states, history would present much fewer difficulties and contradictions. The progress of

great changes in the manner of dividing time; and thus, whilst some nations have been ready to give their calendar every possible advantage of a scientific construction, the prejudices of others have rendered them unwilling to depart from their accustomed mode, however inaccurate. It may be curious and instructive to trace, very briefly, the changes of the calendar, ordinarily called the changes of style.

The Romans called the first days of each month *Calends*, from a word which signified called, because the Pontiffs, on those days, called the people together, to apprise them of the days of festival in that month. Hence we derive the name of Calendar.

The Roman Calendar, which has, in great part, been adopted by almost all nations, is stated to have been introduced by Romulus, the founder of this city. He divided the year into ten months only,—*Mars*, *Aprilis*, *Maius*, *Junius*, *Quintilis*, (afterwards called *Julius*), *Sextilis*, (afterwards called *Augustus*), *September*, *October*, *November* and *December*. *Mars*, *Maius*, *Quintilis*, and *October*, contained 31st days, and each of the six others months 30 days, so that the ten months comprised 304 days. The year of Romulus was, therefore, of 50 days less duration than the lunar year, and of 61 days less than the solar year, and its commencement, of course, did not correspond with any fixed season. Numa Pompilius, corrected this calendar, by adding two months, *Januarius*, and *Februarius*, which he placed before *Mars*. Julius Cæsar, being desirous to render the calendar still more correct, consulted the astronomers of his time, who fixed the solar year as 365 days, 6 hours, comprising, as they thought, the period from one vernal equinox to another. The six hours were set aside, and, at the end of four years, forming a day, the fourth year was made to consist of 366 days. The day thus added, was called *intercalary*, and was added to the month of February, by doubling the 24th of that month, or according to their way of reckoning, the sixth of the *calends* of March. Hence the year was called *bissextile*. This almost perfect arrangement, which was denominated the *Julian style*, prevailed generally throughout the Christian world, till the time of Pope Gregory XIII. The Calendar of Julius Cæsar was defective in this particular, that the solar year, consisting of 365 days, 5 hours, and 49 minutes, and not of 365 days, 6 hours, as was supposed in the time of Julius Cæsar, there was a difference between the apparent year and the real year, of eleven minutes. This difference at the time of Gregory XIII., had amounted to ten entire days, the vernal equinox falling on the 11th instead of the 21st of March, at which period it fell correctly at the time of the Council of Nice, in the year 325. To obviate this inconvenience, Gregory ordained, in 1582, that

the 15th of October should be counted instead of the 5th, for the future; and to prevent the recurrence of this error, it was further determined, that the year beginning a century, should not be *bissextile*, with the exception of the beginning of each fourth century. Thus 1700 and 1800 have not been *bissextile*, nor will 1900 be so, but the year 2000 will be *bissextile*. In this manner, three days are retrenched in four hundred years; because the lapse of the eleven minutes makes three days in about that period. The year of the Calendar is thus made, as nearly as possible, to correspond with the true solar year, and future errors of chronology are avoided.

The adoption of this change, which is called the *Gregorian*, or *New Style*, (the *Julian* being called the *Old Style*), was for some time resisted by states not under the authority of the See of Rome. The change of the style in England was, established by an Act of Parliament passed in 1752. It was then enacted, that the year should commence on the 1st January, instead of March 25th; and that in the year 1752, the days should be numbered as usual until September 24, when the day following should be accounted the 14th of September, omitting 11 days. The *Gregorian* principle of dropping one day in every hundredth year, except the fourth hundredth, was also enacted. The alteration was, for a long time opposed by the prejudices of individuals; and, until lately, with some persons, the *Old Style* was so pertinaciously adhered to, that rents were made payable on the old quarter days, instead of the new. The Russians still retain the *Old Style* thus creating an inconvenience in their public and commercial intercourse with other nations, which, we trust, that the growing intelligence of the people will eventually correct.

During the period in which France was a Republic, the authorities introduced an entire change in the calendar, which was in existence more than twelve years; and is important to be noticed, as all the public acts of the French nation were dated according to this altered style. The National Convention, by a decree of the 5th October 1793, established a new era, which was called, in the place of the Christian era, the *Era of the French*. The commencement of each year, or the first "*Vendémiaire*," was fixed at the midnight commencing the day on which the autumnal equinox fell, as determined at the observatory at Paris. This era commenced on the 22nd of September 1792, being the epoch of the foundation of the Republic; but its establishment was not decreed till the 4th "*Frimaire*" of the year II. (4th November, 1793). Two days afterwards the public acts were thus dated. This Calendar existed till the 10th "*Nivose*," year XIV. (the 31st December, 1805), when the *Gregorian* mode of computation was restored.—*Madras Almanac*, p. 70 to 74.

Malab, Vol. IV, P. 107 tab. 52, Calyx 5, partite, Petals 5 patent: Anthers 10 on the throat of the stamen tube, short ten lobed lobes reflexed, anthers opposite to the lobes and about equal to them, oblong ovary seated on a short disk 3 celled ovules 2 in each cell collateral pendulous style, columnar stigma 3 partite the lobes conical, Fruit drupaceous by abortion celled 1 seeded. Leaves simply pinnated. Leaflets unequal sided glabrous servated panicles axillary number of parts of flower occasionally decreased by a fifth. A middling sized tree (20 feet) flowering in the hot season, it differs from all the other species in having a one celled, one seeded nut though the germ has uniformly five cells with one or two ovula in each (Roxburgh O. C.) It is found more or less abundantly in all parts of the Peninsula of India. It has also been observed in Ceylon, Ava, the Tenasserim Provinces, Java, &c. In the latter places as in Burmah it is chiefly cultivated for its medicinal properties.—Mason.

The Azadirachta Indica is very common in India. Every part of this tree, especially the bark, is bitter. The bark is also astringent; the leaves are very bitter and nauseous; from the ripe pericarp of the fruit a bitter fixed oil is expressed. Mr. Piddington believes that he has obtained the bitter principle in a crystallised form. But the properties of this tree are imperfectly determined.

The bark is considered by native practitioners as among their most valuable tonics, and is given with aromatics in fever. Dr. White of Bombay used the bark as a febrifuge and almost with the same effect as Cinchona. The Madras Report considers it superior to Rohun bark.

Jadubehunder Sett of Bareilly reports finding extract of neem bark very useful in the treat-

## BALACHIAN.

ment of ague. It is certainly a substance well adapted for use in Dispensaries.

It has been given both in decoction and in extract.—*Ind. Ann. Med. Sc. for April 1856 p. 393.*

(190) AZALEA. Species of this plant are repeatedly noticed by Mr. Fortune. At one place, he says that the *Murraya exotica*, *Aglaia odorata*, *Ixoras*, and *Lagerstroemias* are very ornamental in autumn. Of the Azaleas, the principal kinds grown were *Azalea indica*, *alba*, *phœnicea*, *lateritia*, *variegata*, and the yellow *Azalea sinensis*. He found the latter plant wild on the Ningpo hills, so that there is no doubt of its being a genuine Chinese species. The air at one season around Fa-tee is perfumed with the sweet flowers of *Olea fragrans*, and the *Magnolia fuscata*, both of which are grown extensively in their gardens.—*Fortune's Wanderings, page 153.*

*Azalea ovata* Lindl., he says, is certainly one of the finest and most distinct plants of this kind which he has introduced, and it also grows wild on the hills, and was in full bloom at this period.—*Page 317.*

At one place he found several species of *Azalea* covering the sides of the hills at least fifteen hundred feet above the level of the sea.—*Page 21 & 22.*

He says also *Azaleas* abound on the hill sides of this island. Most people have seen and admired the beautiful azaleas which are brought to the Chiswick fetes, and which, as individual specimens, surpass in most instances those which grow and bloom on their native hills, but few can form any idea of the gorgeous and striking beauty of these azalea-clad mountains, where, on every side, as far as our vision extends, the eye rests on masses of flowers of dazzling brightness and surpassing beauty. Nor is it the azalea alone which claims our admiration; clematises, wild roses, honey suckles, the *Glycine*, and

## BAMBOO.

a hundred others, mingle their flowers with them, and make us confess that China is indeed the "central flowery land." There were several species of myrtaceous and ericaceous plants, which are also common on the hills, but no species of heath has ever been found, and he believes the genus does not exist in this part of the country.—*Fortune's Wanderings, p. 67.*

At a subsequent visit, he found in the hedges the last fading blossoms of the beautiful spring-flowering *Forsythia viridissima* still hanging on the bushes, while several species of wild roses, *Spiræa Reevesiana*, clematises, and *Glycine sinensis*, were just coming into bloom. But higher up, on the gorgeously painted hill-side, were masses of yellow and white flowers. The yellow, was the lovely *Azalea sinensis*, with its colours far more brilliant, and its trusses of flowers much larger, than they are ever seen in any exhibition in Europe. The white was the little known *Amelanchier racemosa*. Amongst these and scattered over the hill sides, were other azaleas having flowers of many different hues, and all very beautiful.—*A Residence among the Chinese, p. 27.*

(191) AZAN, *Arab.* The Mahomedan summons to prayer, proclaimed by the Moazzan: the words used, some of which are repeated, mean God is Great, I bear witness there is no other god but God, and I bear witness that Mahomed is indeed the prophet of God. Come enliven your prayers. Come for refuge to the asylum. God is great. There is no god but the true God.—*Herkl.*

(192) AZURE STONE or lapis lazuli is said to be found massive with iron pyrites, amongst the Ajmeer hills, especially the Nag-puhar range: this stone is sold by all "attars" both as a medicine and as a pigment: though found in the district, it is also imported into Ajmeer from Bombay: the native name, in Ajmere, is "laj-burd."—*Genl. Med. Top. p. 162.*

## B.

(193) BALACHIAN. Is a condiment prepared from small fishes of all descriptions and shell fish. The ingredients are placed in a pit to undergo fermentation, and afterwards dried, pounded and preserved with spices. With the Malays, Siamese, Burmese and Cochin Chinese, Balachian has become a necessary of life, as it serves to season the daily food of these nations.

According to Ainslie, Blachang or Balachang, is a sort of a caviare of a very strong odour, prepared with the spawns of shrimps, and shrimps themselves on Sumatra and other Eastern islands whence it was brought to India, in his time; but it is not now known on the coast side.—*Ainslie's Mat. Med. p. 144.*

(194) BAMBOO. The roots are carved into fantastic images of men, birds, monkeys, or monstrous perversions of animated nature, cut into lantern handles and canes, or turned into oval sticks for worshippers to divine whether the gods will hear or refuse their petitions. The tapering culms are used for all purposes that poles can be applied to carrying, supporting, propelling, and measuring, by the porter, the carpenter and the boatman; for the joists of houses and the ribs of sails, the shafts of spears and the wattles of hurdles; the tubes of aqueducts, and the handles and the ribs of umbrellas and fans.

The leaves are sewed upon cords to make rain cloaks, swept into heaps to form manure, and

## BAMBUSA ARUNDINACEA.

matted into thatches to cover houses. Cut into splinths and slivers of various sizes, the wood is worked into baskets and trays of every form and fancy, twisted into cables, plaited into awnings and woven into mats for scenery of the theatre, the roofs of boats, and the casing of goods. The shavings even are picked into oakum and mixed with those of rattan to be stuffed into mattresses. The bamboo furnishes the bed for sleeping and the couch for reclining, the chopsticks for eating, the pipe for smoking and the flute for entertaining, a curtain to hang before the door and a broom to sweep around it; together with screens, stools, stands, and sofas for various uses of convenience and luxury in the house. The mattress to lie upon, the chair to sit upon, the table to dine from, food to eat, and fuel to cook it with, are alike derived from it, the ferule to govern the scholar, and the book he studies both originate here. The tapering barrels of the tong or organ and the dreaded instrument of the doctor—one to make harmony and the other to strike dread, the skewer to pin the hair and the hat to screen the head, the paper to write on, the pencil handle to write with and the cup to hold the pencil, the rule to measure lengths, the cup to gauge quantities and the bucket to draw water, the bellows to blow the fire, and the bottle to retain the match, the bird-cage and crab-net, the fish-pole and sumpitan, the water wheel and aqueduct, wheelbarrow and hand cart &c. &c. are one and all furnished or completed by this magnificent grass, whose graceful beauty when growing is comparable to its varied usefulness when cut down.—*Williams' Mid. Kingdom*, page 277.

### *The plant.*

Bans, BENG. | Mungil or Munkil, TAM.  
Mulka, Vedroo, TEL.

It delights in a rich moist soil, as the banks of rivulets, lakes &c. among the mountains.—*Roxb. page 191.*

The Tamul medical practitioners say the root is diluent; that the bark cures eruptions; the leaves are esteemed emmenagogue and that the tabasheer, which is found in the old cavities of the joints of this species, is useful in paralysis and flatulence. The seed is used for food.—*Roxb. page 192.*

### *The young plant.*

Moonghill koortoo, TAM. | Vedoorookoortoo, TEL.  
Bas ke kaonlie sakh. DUK,

Moonghill koortoo is the Tamool name of young Bamboo plants, when they have risen but a few inches from the ground. The Natives prepare with them a very pleasant tasted pickle.

## BANYAN.

### *The seed.*

Moonghill arisee, TAM. Vedooroo Beeum, TEL.  
Bans ke chawul, TEL. Vanoo, SANS.

This is generally eaten boiled with milk; or with animal food, spices, salt and water, it is made into broth.—*Ainslie, page 219.*

(197) BAMBUSA BALCOOA. Roxb. There are two varieties, the Balkoo-bans, Bengal, also Dhooli-Balkoo. The former variety has a smaller cavity, and on account of its size and strength is reckoned the best for building purposes, scaffolding &c.—*Roxb. Vol. II. page 196.*

(198) BAMBUSA BACCIFERA.

Beesha, TAM. | Pagutulla, CHITTAGONG.

Is indigenous in the Chittagong mountains. It bears a berry, one seeded and yields tabasheer.—*Roxb.*

(199) BAMBUSA NANA.

Ken-fa, CHINESE.

A native of China, but introduced into Calcutta. It makes most beautiful hedges.—*Roxb.*

(200) BAMBUSA SPINOSA.

Behorbaus, BENG.

Is found in the vicinity of Calcutta. It is strong and is employed for various useful purposes.—*Roxb. p. 199.*

(201) BAMBUSA STRICTA.

Sadanapa Vedroo, TEL.

Grows in dry situations, and used as spear shafts.—*Roxb. Vol. II. p. 193.* *Bambusa Stricta* of Behar, is of a green colour, and is unlike the other species of this genus, all of which are yellow or white.—*Hooker. Vol. I. p. 30.*

(202) BAMBUSA TULDA.

Tulda-baus, BENG. | Peka-baus, HIND.

This is the common bamboo of Bengal, where it grows in the greatest abundance. It flowers in May. Its varieties are the *Jowa-baus*; the Basini-baus, employed in basket making and the Behoor-baus of the Bengalees. A staff of the Behoor-baus must be placed in the hand of every young Brahmin, when invested with the sacerdotal cord.—*Roxb. Vol. II. p. 196.*

(203) BANYAN. Lady Faulkland tells us that about eight miles from Wacee is a banyan tree, covering a space of ground between three and four acres. The road to it is along the valley. Under this magnificent tree, she says, I remained some hours. The shade was so complete, I could sit in the middle of the day without any covering on my head.

The tree was of such a size that separate picnic parties might take place under it, and not interfere with each other. There were countless avenues, or rather aisles, like those of a church, the pale-gray stems being the columns, which, as the sun fell on them, glittered in parts like silver; and here and there were little recesses like chancels.

## BARLERIA PRIONITIS.

where the roots from the boughs formed themselves into delicate clustering pillars, up and down which little squirrels were chasing each other; while large monkeys were jumping from bough to bough, the boughs cracking and creaking, as if both monkeys and boughs would fall on my head. There are many banyan trees, of great size, in this part of India; but I have never heard or read of any larger, or more perfect, than this. The exact area shaded by it at noon-day is, by careful measurement, three acres and three-quarters. The space covered is a very symmetrical oval. There is no brushwood underneath, nor anything to interrupt the view, except the numerous stems of the tree itself. The tree is so regular in its external shape, as to take off in some degree, from its beauty, it looks, at a little distance, like a closely-planted clump of trees, or a gigantic green mushroom; but in every other respect, seen from underneath, it is beautiful, whether in the heat of noon-day, or in the dark night, when the servants and camp-followers have lighted their watch-fires in its lofty aisles; or, perhaps, most of all, when a bright moon-light struggles through some of the few openings in the leafy canopy. I really did not wonder at its being regarded by the simple villagers as a deity; and many were the marvels they related of the punishments inflicted on those who had violated its sanctity. One story runs that an impious Soobadar, who ruled the district in former days, having more regard for his own comfort than for the sacred tree, caused two of the descending shoots or roots, or whatever the pendulous boughs should be called, to be cut as poles for his palanquin. But he was so terrified by a frightful vision of the tree-goddess, who appeared to him the first time he reclined in the palanquin, that he made large offerings to her, to atone for his act of sacrilege, and placed the poles he had impiously cut in the little village temple hard by, where they still are to be seen.—*Chow-Chow*, p. 206.

(204) BARK STRINGS, and BARK ROPES, are made from fibres by the Hill tribes of Rajmahal.—*Royle*.

(205) BARLERIA LONGIFOLIA. Lin.

*The root.*

Neer moollie vayr, TAM. | Neer goobbie vayroo, TEL.  
Gooshura, HIND. | Hchoora, SANS.

This, the root of the long leaved Barleria, has got its Tamool name from being generally found growing in moist situations. It is supposed to have virtues similar to the Moollie vayr.—*Ainslie's Mat. Med.* p. 39.

(206) BARLERIA PRIONITIS. Lin.

Shemmoollie elley, TAM. | Moollooghoruntch, TEL.  
TAM. | Kooruntaka, SANS.

## BASSIA LONGIFOLIA.

The juice of this leaf which is slightly bitter, and rather pleasant to the taste, is a favorite medicine of the Tamool practitioners, in those catarrhal affections of children which are accompanied with fever and much viscid phlegm: it is generally administered in a little honey, or sugar and water.—*Ainslie's Mat. Med.* p. 111.

(207) BARARM RIVER. The Barram river is situated about 80 miles south of Labuan.

(208) BARRINGTONIA ACUTANGULA.

Jsjeria Samustranadi, | Ijul, Hijul, BENG.  
TAM. | Cademie, TEL.

This species is common in most parts of India, it grows to be a large handsome tree; in appearance it is like a well shaped, regular middle sized oak—it flowers about the beginning of the wet season, its long pendulous racemes of scarlet coloured flowers give it at that time a most elegant appearance.—*Roxb. Rohde. M.S.S.*

This tree grows in the north west provinces of Hindostan, principally about Saharunpore. The seeds are officinal and used by the Indian doctors.—*Dr. Honigberger*, p. 241.

(209) BARRINGTONIA RACEMOSA.

A stout timber tree, a native of the Malacca islands, the Delta of the Ganges, Malabar &c.—*Roxb.*

(210) BASELLA ALBA. Lin.

Codipessaci, keeray TAM. | Tinghe Batsalikoora, TEL.  
Bayl ke butchla ke baujee, | Kolumbi, SANS.  
Duk. | —*Ainslie*, p. 253.

(211) BASSIA LONGIFOLIA, Lin.

*Eloopiemarum*, TAM.

Long leaved Bassia tree. According to Ainslie, this is reckoned a useful wood in house building, and for making doors, windows, &c. &c.—*Ainslie's Mat. Med.* p. 209.

*The oil.*

Eloopei umay, TAM. | Ippa noonay, TEL.  
Mohe ka tail, DUK.

This is an expressed oil obtained from the olive shaped seeds of the five celled fruit of the Bassia longifolia. It is used by the common people not only as a substitute for ghee but for burning in lamps.—*Ainslie's Mat. Med.* p. 263.

*The tree.*

Ippa, TEL. | Mooa, BENG.  
Ilupi, TAM. | Tchnee, CYNG.  
Ipie, CAN.

This is a native of the Peninsula of India and found in plantations along the southern part of the coast of Coromandel. It flowers during the hot season in the month of May, the seed ripens in August and September.

The following were given as the economical uses of the Ilupie tree. Bassia longifolia, by the Rev. Dr. John of Tranquebar.

## BAST OR NAR.

1. The oil pressed from the ripe fruit is used by the Natives as common lamp oil.

2. It is a principal ingredient in making the country soap and keeps therefore often the same price with the cocoanut oil.

3. It is to the common people a substitute in place of ghee and cocoanut oil in their curries and other dishes. They make cakes of it, and many of the poor get their livelihood by selling these sweet oil cakes.

4. It is used to heal different out breakings, such as the itch &c.

5. The cake left after the oil is expressed is used for washing the head, and is carried as a small article of trade to those countries where these trees are not to be found.

6. The flowers which fall in May are gathered by the common people, dried in the sun, roasted and eaten as food. They are also bruised and boiled to a jelly and made into small balls, which are sold or exchanged for fish, rice, and various sorts of small grain.

7. The skin is taken off from the ripe fruit as well as the unripe, and after throwing away the unripe kernel boiled to a jelly and eaten with salt and capsicum.

8. The leaves are boiled with water and given as a medicine in several diseases to both men and cattle.

9. The milk of the green fruit and of the tender bark is given also as a medicine.

10. The bark is used to cure the itch.

11. The wood is as hard and durable as teak wood but not so easily worked, nor is it procurable of such a length for beams and planks, except on clay ground where it grows to a considerable height, but in such a soil does not produce so many branches and is less fruitful than when in a sandy or mixed soil which is the best for it. In a sandy soil the branches shoot out near to the ground to a great circumference, and give more fruit. These trees require but a little attention and watering during the first two or three years in the dry season and being of so great use there should be plantations of them on high and sandy grounds, where no other fruit tree will grow.—*Rohde M.S.S.*

(212) BAST OR NAR, from the large Australian or rather Cape tree (*acacia robusta*) so common on the Neilgherries. In January 1854 Mr. McIvor first used this bast and it has since been in use in the gardens for all purposes to which Russian bast is applied in gardens in Europe. The material is strong, tough, and durable also pliable when wetted; No. 1 Specimen of the bark as taken off the tree; No. 2 prepared for tying plants. No. 3 for twisting into rope. This bast could be procured cheaply and in large quantities, as the roots when the trees are cut

## BAUHINIA VARIEGATA.

down throw up numerous young shoots to the height of from 6 to 12 feet in one year. The bark of this tree is also a powerful tan.—*Mr. McIvor.*

(213) BATAVIA. The ancient Jakatra, situated on the banks of the large river Tji-li-wung, in Java, has always been the capital of the Dutch possessions there. According to M. Temminck, the population in 1832, was nearly 118,000, as follows:—

Europeans.	2,800	Moors and Arabs.	1,000
Chinese....	25,000	Slaves.....	9,500
Natives....	80,000	Total...	118,000

No. 3, *Jour. Ind. Arch.*

(214) BAUHINIA PARVIFLORA. ARI NARA.

Archa maram, TAM.

A small uncommonly crooked bushy tree a native of most forests on the coast of Coromandel, the bark furnishes the matchlockmen with their matches, *Jauiki tadoo*; it burns long slowly without the help of Saltpetre or any other combustible: to prepare the bark it is boiled, dried and beat. Ropes are also made of the inner rind which is fibrous strong and durable.—*Rohde, M.S.S.*

(215) BAUHINIA DIPHYLLA, one of the most common of barks is the *Bauhinia diphylla*, called Authee nar, Yepy, and Apa. This is a strong coarse brown bark of which the Natives make temporary ropes for securing thatch, matting or fences. The barks of several other Bauhinias are used for the same purposes. The Ara nar is the bark of the *Bauhinia parvifolia*, of which matches for native guns are made.

(216) BAUHINIA TOMENTOSA. Lin. DOWNY MOUNTAIN EBONY.

Caat Attie poo, TAM. | Usmadugha, SANS.

The small dried buds and young flowers of this species of Bauhinia, which is the Canschena puu of the Hort. Mal., the Native practitioners prescribe in certain flux cases; they have little sensible taste or smell, though the leaves of the plant when fresh and bruised, have a strong but not unpleasant, odour. Rheede tells us in the H.'s M.'s (Part 1. p. 64) that a decoction of the root of the bark is given on the Malabar Coast, in cases where the liver is inflamed.—*Ainslie's Mat. Med. p. 73.*

(217) BAUHINIA VAHLII, is a tree which grows in the north-west provinces of India, near the mountains. The kernels of the large and broad pods have a sweet astringent flavor, and are eaten like almonds by the natives. When the husks are fresh the natives roast them to get at the kernels, when old, they open of themselves: it is said the kernels possess tonic and aphrodisiac properties.—*Dr. Honigberger, p. 241.*

(218) BAUHINIA VARIEGATA. Its buds are sold fresh in the bazar at Lahore as a vegetable, which are eaten prepared with animal food.—*Dr. Honigberger, p. 241.*

(219) BAWEAN. The Island of Bawean, or following its old name Lubek, forming a portion of the Residency of Sourabaya, lies about sixteen Dutch (forty-eight English) miles to the north of Ujong Pangka, in  $5^{\circ} 30'$  South latitude and  $112^{\circ} 38'$  W. longitude (Greenwich) and contains about 36 square (Dutch) geographical miles or 44 English miles.

The country in general is very mountainous, and it is only near the sea that some plains are found, on the largest of which, about  $3\frac{1}{2}$  miles in circumference, the principal village Sangkapura is situated.

The highest mountains which present themselves on the Island are the Gunong Tingi and Gunong Rajah, the height of which differs little from each other and may amount to 2,000 feet above the level of the sea.

There we have a most impressive panorama over the whole Island. The thermometer shewed at midday  $75^{\circ}$ ; the air is fine, but at the same time humid.

The ground of Bawean, which bears all the marks of volcanic origin, is fertile, being adapted not only for the cultivation of rice, but also for that of cotton, indigo, and tobacco.

The ground also furnishes coal, which is found in the vicinity of the dessa Kalompe, and if search were made for it, it would possibly be found in other parts.

In the vicinity of the same dessa the naturalist Diard, at the time of his visit to this place in the year 1840, found a kind of white sand eminently adapted for covering melting furnaces. Several cargoes of it have already been exported for the arsenal at Sourabaya, as well as by private individuals, and it has been proved by trial that it is of superior quality to the sand brought from Europe for the same purpose.

Although warm springs are found, they appear to contain only a little sulphur, but to have a large measure of alum. There are dispersed over the whole island, being found as well in the vicinity of the dessa Kepoog on the east coast and around the dessa Gellam in the west, as in the vicinity of the capital. The hottest has a temperature of  $125^{\circ}$  Fahr. These springs, of which the water has much resemblance to Seltzer water, are generally very efficacious in cutaneous diseases, and they are therefore used in the good effect by the inhabitants when such disorders occur.

There is little dense jungle. The *Champlong* alone not only attains a thickness unknown in Java but is also finer, and when made into furniture, is scarcely distinguishable from the *Kaya Ambailo*. In the country around the dessa Gellam, the *Kaya Puti* tree occurs in great abundance; but owing to the inhabitants of Bawean not knowing how to extract the well known oil the leaves and fruit only are used as medicine. Although in former years

thick *Jati* wood was found it has now entirely disappeared; the whole island having become divested of it from the inhabitants having cut it down for the building of prahus and houses; so that it has now to be imported from Java. The *Kayu Sona* which was found in great abundance, has met with a similar fate. The brushwood with which all the mountains are covered is only fit for fire-wood. Some shrubs are also found which do not occur in Java; amongst other the *Kayu Anyang*, the fruit of which sells in Java at 30 florins per picul, and a number of wild flowers which have a very beautiful appearance. The so called ivy in particular varies very much in its kinds.

We miss many of the fruits which are cultivated on Java. There are only found different kinds of mango, pisang, the blimbing, the pomplemos, and some durian trees. A fruit known under the name of *bua Kayu pait*, which so far as is known does not exist in Java, is here found in abundance, particularly in the country around Sungie Trus. The tree reaches a height of 30 feet, and presents a beautiful appearance when it is covered with fruit. The fruit is in bunches of a deep red colour, is milky, of an agreeable flavour, and has some resemblance to the *Sawo* fruit.

The inhabitants for the most part use *cachang*, or for want of it, *jarak* oil.

The pinang tree is extensively cultivated, principally in the country surrounding the dessas Sukela, Dissallan and Kalompe, so that there is a large export of it, amounting annually to about 3,000,000. The *aren (gomute)* tree is in great abundance; and besides furnishing the inhabitants with the refreshing sap of which they are very fond, gives 40 to 50 picul of aren sugar for exportation. We also meet in tolerable abundance the proper Amboyna sago tree of which the sago is excellent, and of which the natives make use after the planting of the paddy. The greatest quantity is found in the country around the dessa Talook-dalem.

After the paddy harvest the sawas are made over to any one for the cultivation of vegetables amongst which are the *Katella*, *bintool*, *Kaladie*, and a very little *jagong*, including the so called *Jagong-kodok* which only requires to be two months in the field before it is cut, and which yields a small grain and at the highest reaches a length of 4 or 5 inches.

On the other hand there are numerous and very large monkeys. There is perhaps no island in the Archipelago so abundantly furnished with these troublesome and even hurtful animals. They are not malicious but beyond measure forward, so that they frequently oblige those who live in isolated places to remove their dwellings.

In the year 1844, in the month of July, says this writer, when making my ordinary round, I

had one day just dismounted from horseback to follow a couple of deer which had shown themselves on the road, when I observed a family of apes who had taken possession of a solitary Javanese dwelling, shaded by fruit trees and bambus, the inhabitants of which, with the exception of an old woman, were absent. The apes had entirely gutted it, although the old woman was beating round with a bambu, and four children who were playing in the vicinity kept up a clamour. They were just ready to seize a copper pot full of rice when two well directed shots put a stop to this scene. Of the spoil taken by them very little was recovered. The old woman died shortly afterwards from the fright. The *tengalong* or so called civet cat is extremely large, lives in a very solitary manner, and is in much request on Java for his excellent qualities. The *límak* is also found here, but in small number. The porcupine is also found, and is somewhat larger than on Java. Besides the water snakes, of which different varieties are found, there exist also the *ular wellang*, *ular sawa*, the *ular luwook*, the *ular biren*, and the *ular pendjallin*. The first named is alone dangerous from its poisonous bite. It is principally when young that its poison is so noxious. Instances have occurred of men who have been bitten dying in a few seconds. Leeches are totally wanting, Scorpions and caterpillars are abundant. The alligator is seldom or never found, but on the other hand there are many guanos which inhabit all parts of the island. Lizards are found of different kinds.

Besides the *byo*, the large white and blue wood pigeon is met here, the first known in Java under the name of *kadanchar*, and on Banda under that of the nutcracker, the last, of the same genus, is somewhat smaller; they are here called, the first *Burong Berrom*, the second *Kudawa*. The lovely green pigeon also frequents the vallies but in small numbers.

The celebrated and palatable fish called *bandeng*, which has the most resemblance to our salmon, does not breed here as in Grisse, because there are no fish ponds. It is never caught in the sea, notwithstanding at the change of the east and west monsoon, the coast is yearly visited by Madurese fishers who come to catch the young *bandeng* for the fish ponds, and who sell them at Grisse the redan of 5,500 small fish for 18 rupees and more.

The island is divided in three districts, viz. Sankapura, Kulon Negerie and Wettan Negerie. Sankapura consists of a union of 17 campongs which constitute the head station, and contains a circumference of  $3\frac{1}{2}$  miles. Sankapura has a population of 6,770 souls.

*Kulon Negerie* has 26 dessas, with a population of 11,826 souls and 2,881 houses. Under its jurisdiction is found the Birds nest rock Nusa,

ance from the nests found in it, which are rented by government, but the traveller will not repent visiting it. The circumference is 80 feet, height 50, and the beautiful cave which has been formed in it by nature has a circumference of 55 feet and is about 18 feet high. Notwithstanding the raging surf which breaks against the cliff, the water within, which has a depth of  $1\frac{1}{2}$  fathoms, is in a dead calm; and superb is the sight from within this cave as we see the foaming waves breaking themselves against the steep rocks and flowing calmly in. The summit of this rock is covered with sea grass, and numerous sea mews have chosen this place to lay their eggs.

In the neighbourhood of the dessa *Patter* we find a subterranean gallery (called *Gowa*) the depth of which is not known by the natives, probably on account of their belief that it is filled with serpents which appeared in human form, and in consequence being considered as holy, receives many pilgrimages. This popular legend and superstition however was destroyed, to the vexation of many hajis, in the month of July 1844, when he visited the cave in company with Mr. J. A. Jacobs and some chiefs, and measured it exactly. The depth was found to be about 200 fathoms. He had it is true much opposition from bats and were several times left in utter darkness by the torches being extinguished, but his trouble was recompensed, for he doubts whether there is a more beautiful subterranean cave to be found in the whole Archipelago.

About 3 miles to the north of this cave there is a very romantic waterfall about 70 feet high, the water of which forms the river of Sungi-toppo, which waters many paddy fields. It is remarkable that the bay of Promahan situated in this part, is the richest in fish of the whole island and above all abounds in the so much prized *bandeng*, *blanak* and *ikan kembong*, which are scarcely found in the other bays. Once or twice in the month, according as the water and wind serves, this fine bay is fished, which is done with the *krakat*, a kind of dragnet about a hundred fathoms long, and it not unfrequently happens a haul yields 1,000 and more fishes, amongst which *bandeng* are chiefly found,  $2\frac{1}{2}$  feet long and 8 inches broad, and a great number of *kembongs*.

The Baweans, probably descendants of the Madurese, whose language with a few modifications prevails, differ from them in dress; but in this respect agree closely with the Bugis. The inhabitants of the dessa *Dipanga* employ the Javanese language.

The principal articles of export are, first, mat-work, consisting of sleeping, couch and chair-mats, rice baskets and siri boxes. The plant called *pandang*, which is arranged into three kinds and which has much resemblance to the above, furnishes the principal material of this branch of

abundance. The first kind, which gives the largest leaves, is used in the preparation of couch and sleeping mats, the second, having a leaf of medium length, for a smaller kind of sleeping and chair mats, the third is only used in the plaiting of siri and tobacco boxes. After being cut the prickly border of the leaf is removed by means of a horse hair, after which it is divided in proportion to the coarseness or fineness of the matting, next made smooth by means of a round piece of wood which runs between the fingers, and last being boiled is placed in running water in order to stretch it. After having been dried in the wind and acquired a glistening white colour it is fit for use. The manipulation with the plaiting which follows is entirely done by women, who employ themselves with it in *duroongs*, before their houses. The *duroongs*, about which the respectable Baweans make more work than about their houses, are not infrequently 20 feet long and 10 feet broad, and have a value of 80 or 90 \$ dollars. They are the same as what the Javanese call *limboong*, but with this difference, that in the *duroong* the paddy is stored above, while the lower part is used for the weaving of cloth and the plaiting of mats. In feasts also the food is eaten there. Of the kind of mats that have been mentioned about 180,000 to 200,000 are annually exported to Java and other places, having a value of about 60,000 guilders. There is also a considerable trade in mill stones, stone mortars and clothes. The first two articles are chiefly prepared in the dessa Tellock dalem, and the last are woven by the women in the absence of the men—the requisite thread being imported from Joana—and are mostly destined for the retail trade, principally in the Lampongs.

During the good season *Paduwangs* to the number of 60 to 70, arrive in succession from Madura, laden with rice and kachang oil, also with dried fish or trassie (blachang) which they barter for betel nuts of which the exports, as has already been mentioned, amount to 3,000,000. —*Journ. Ind. Archip. Vol. V. No. 7.*

(220) BEAD SEEDS. Wild Jamaica Liquorice seed, *Abrus precatorius*, Lin.

Coondoomunny, TAM.	Retti, HIND.
Goomchie, DEK.	Telae, MALAY.
Ghoorie Ghinza, TEL.	Ractica, SANS.

The beautiful round seeds of the *Abrus precatorius* which are either red or white, are strung together and made into necklaces, bracelets and other ornaments. The white sort resemble pearls. They are also bruised into a fine powder by the goldsmiths and in this state used to increase adhesion, in joining together the more delicate parts of golden ornaments.—*Ainslie's Mat. Med. p. 142.*

(221) BEARS PAWS are regarded by the Chinese as a delicate dish though perhaps not the

most so which can be eaten, as is remarked by Mr. Gutzlaff.—*Williams' Middle Kingdom, p. 246.*

(222) BEATI MARAM, or Bombay black wood;—a wood which grows in Malabar and Travancore to a large size; some trees five feet in diameter, and fifty feet long, have been brought from Travancore, but the wood is generally not more than twenty or twenty-five feet long, and from twenty inches to two feet in diameter. It might be procured in great quantities in Travancore and the Cochin forests. Much of this wood is used in England, and called rose wood. Its general uses in India are for house furniture: great quantities are exported to Bombay, Madras, and Calcutta, for that purpose.—*Edye M. and C.*

Beauty or Carroo Marum Black wood, *Dalbergia latifolia* is common in Wynaad on open grass lands where the tree attains a great size.—*M. C. Jour.*

(223) BECHHACORI. A wood of and called in, Nepaul, Sulla and Surrendhool, or Dhoobkee (on account of its resinous quality). It is chiefly consumed in Nepaul. Its branches are used as torches: the fragrant turpentine which it yields is employed in sacrifices, and in medicated salves, and its wood is converted into rafts for houses.—*Smith's 5 years p. 67.*

(224) BEERBHOOM. Copper, Lead, and Iron Ores, at Deoghur, near Beerbhoom.

In the columns of the Calcutta papers of the 5th instant appears an official notice of the discovery of Copper, Lead, and Iron Ores at Deoghur, near Beerbhoom. Deoghur, or Byjnath, is a small town in the zilla of Beerbhoom, famous for its temples, visited every year by thousands of pilgrims from the Northwest Provinces of India. It is situated in the great table-land which extends from near Burdwan to Dunwa Ghaut, in Behar. The existence of the veins was made known as a great secret by a Bunnia about a year ago, the first visit being made to it by stipulation at dead of night. Granite, Syenite, and Gneiss, traversed by Greenstone veins, are the prevailing rocks around—the usual matrices of copper and lead veins all over the world: the soil consists of red and white gravel, composed of quartz and felspar, the detritus of these. The country all around is well wooded—much of it, indeed, is dense jungle: near the vein is a mountain torrent, which dries up in the fair season. The surface is undulating, and the drainage seems easy. The metals do not appear ever to have been worked or made use of. The vein at the surface runs east and west—it has been traced for a hundred feet continuously: the metal is partly pure, partly in the form of green carbonate. Veins of lead ore, partly pure, partly in the state of galena or sulphuret, traverse the principal vein at right angles. Both have been analysed, and found of remarkable

richness : the whole question of the value of the discovery consists in the expense of raising the ores and converting them into metal—facts that can only be determined by experiment, and this Government must make. Joint-stock companies are in such ill odour at present that no one will join them : capital is too scarce for individuals to embark in the scheme. Should the adventure look promising, Cornish miners from home may probably be induced to take it up. Provisions and labour seem cheap and plentiful all around, and the country not unhealthy, while hundreds of workmen can be had for one anna, or three halfpence, a day, and the country is such as to admit of carts with solid wheels. These carry about half a ton when drawn by buffaloes, about a third less with oxen. The nearest coal is forty miles off—the nearest point on the river where the ore could be shipped for Calcutta is sixty, the road being tolerable all the way. Considering the description of the country, we should have imagined that smelting might have been most economically managed by the use of the jungle wood on the spot, as neither copper nor lead ores of the description here mentioned are difficult to reduce, and part of the metal in both cases seems pure,—the copper might in all likelihood be separated from the malachite, which would alone remain for something, by stamping and washing—the more especially as there appears to be a convenient water-power close at hand. The existence of copper has been pointed out in the following localities in India—we are not aware of its being at present anywhere worked ;—near Beila, in the province of Lus, on the Western Frontier of Lower Seinde—by Captain Del Hoste and Captain Harris. In Kumaon,—by Lieutenant Gasford, and Captain Durand. At Porkee and Danpoor—by Captain Rickards. At Almorah, and in Afghanistan—by Captain Drummond. In the Nellore and Guntoor Collectorates. It is said to have been worked in Cutch, on the Neilgherries, and near the Phoondah Ghaut, but we are not aware of any specimens having been found in any of these localities.—*Bombay Times, June 19.*

(225) BEES. The charm used in China to keep off bees is a simple one ; viz. a few dry stems and leaves of a species of *Artemisia* which grows wild on the hills, and which is largely used to drive that pest the mosquito out of the dwellings of the people. This plant is cut early in summer, sun-dried, then twisted into bands and it is ready for use. At the commencement of the operation one end of the substance was ignited and kept burning slowly as the work went on. The poor bees did not seem to know what to make of it. They were perfectly good tempered and kept hovering about our heads, but apparently quite incapable of doing us the slightest injury. When the hives were properly fixed in their places the charm was put out, and my host and his ser-

vants carried off the honey in triumph. "Come," said he to the operator and us who were looking on, "come and drink wine." "Ay," said the half-witted priest, "drink wine." So we all adjourned to the refectory, where wine in small cups was set before us.—*Fortune's Residence.*

(226) BEETLES, in one part of Dr. Hooker's Travels, were most rare, and (what is remarkable) the wood-borers (*longicornis* and *Curculis*) particularly so. A large *Telephora* was very common.—*Hooker Him. Jour. Vol. II. p. 65.*

(227) BEGUM. Beebee, Bee, Nissa, Khanum ; Khatoon ; Banoo, HIND. are the respectful terms given to Mahomedan women in India.—*Herklots.*

(228) BELLEROM, the Tamil name of a Malabar wood, which is called in Malabar and Canara *Kyndle*. It resembles the wood named Angely at Cochin and in Ceylon. The Company's cruiser, Aurora, was built, by way of experiment, of this wood, procured from the forests in the north of Malabar ; and it appeared to answer its purpose.—*Edye M. and C.*

(229) BEMBUR, the Tamil name of a tree which grows on the Coromandel coast : it is remarkably durable and strong. The few natives who build vessels on that coast, prefer it to the other woods of the coast, which are not very abundant.—*Edye. M. and C.*

(230) BENINCASA CERIFERA, is the tallow-gourd of China, and remarkable for having its surface, when ripe, covered with a waxy exudation, which smells like rosin.—*Williams.*

(231) BEN OR VEN TEAK. In Tamil, and Bellinger in Malayala.—This tree is much used by the native carpenters for house-building and masts for dories, pattamahs, and other country vessels. It grows to ninety and one hundred feet long, and from twelve inches to three feet in diameter ; it is perfectly straight and without branches, excepting at its top ; the leaves are small and very thick. This wood is not so durable as the peon, but it may be considered of the same texture, although it is very much lighter in colour, and in this respect much resembles the American red oak.—*Edye, M. & C.*

(232) BERBAIT, MALAY, means to make Pantuns, for an explanation of particulars of which see Marsden. Here it may be sufficient to say a Pantun consists of 4 lines, the two first consist generally of simile or natural image and the 2 last a moral drawn from the simile. The Malays take great delight in listening to two poetical champions pantuning at each other till one is obliged to give in from want of further matter.—*Journ. In. Arch. No XI. Vol. V.*

(233) BERGERA KONIGII. Lin.

*The leaf.*

Caraway pillay, TAM.	Karrivaympakoo, TEL.
Karay pauk, DUK.	Kristna, SANS.

With this leaf Europeans, as well as Natives, give a pleasant flavor to curries, molagstannies,

## BIGNONIA QUADRILOCULARIS.

&c. The leaves are also considered as stomachic and tonic. A strong infusion of them (they having been previously toasted) is given, to stop vomiting, in cases of Cholera Morbus.—*Ainslie's Mat. Med.* p. 262.

### (234) BERRIA AMMONILLA.

Trincomalee Wood, ENG. | Hal Mililla, CING.  
Amumilla, CING.

A Native of Ceylon and one of their largest and most useful timber trees much of the wood is annually exported from Trincomalee and is used at Madras by carriage builders for *spokes* of wheels, frames, poles and shafts of carriages also for handles of tools &c. It is inferior to well seasoned Saul for spokes and to the Mimosa Arabica or babool for many other purposes to which it is applied—but it has the advantage of being comparatively light and is easily worked.—*Rohde M.S.S.*

### (235) BEZOAR.

Batu Nakit, JAVANESE.

In the interior of the Rajang district, in Borneo, are found in abundance two species of monkey which produce the Batu Nakit, or Bezoar stone. One is a large black monkey with a long tail called *Nakit*. One is large and red, but has no tail, and is called *basi*. In one out of ten or twenty of these two kinds are found the Bezoar; if not extracted quickly after the death of the animal, it is said to be of inferior size and quality.—*Mr. Burns in No. for Feb. 1849, of Jour. Ind. Arch.*

(236) BHAGAVAD GITA, name of a Sanscrit book translated by Wilkins.

(237) BHAND BHAGTEEAH, HIND.  
Mimics, actors.

(238) BIBLIOTHECÆ SANSKRITÆ A Catalogue, by Professor Gildemeister, of Bonn on the Rhine, published in 1847, of Authors, Indian and European, who have edited or translated Sanscrit works, or treated of Sanskrit literature.—*Cal. Rev.*

(239) BIGNONIA CHELENOIDES. This is a native of the mountainous parts of the coast of Coromandel, where it grows to be a large tree. Flowers during the hot and rainy seasons and the seed ripens in December and January. The wood of this tree is high colored, hard, durable, and of much use amongst the inhabitants of the hills where it is plentiful.—*Rohde M.S.S.*

(240) BIGNONIA INDICA. This is one of the tallest trees on the Coromandel coast, grows up amongst the mountains chiefly. Flowering time the beginning of the wet season. Seed ripens in January and February. The wood of this tree is soft and spongy so much as to render it unfit for use.—*Rohde, M.S.S.*

(241) BIGNONIA QUADRILOCULARIS. A large tree, a native of the Circar

## BINUA?

mountains. Flowers during the beginning of the hot season. The wood of this tree is employed for many purposes by the Natives.—*Rohde M.S.S.*

### (242) BIGNONIA SUAVEOLENS.

Patile, SANS. | Beng, PAML.

A native of Bengal and of the Southern parts of the Coromandel coast: a middle sized tree.—*Rohde, M.S.S.*

(243) BINUA. The Binua of Johore. This is not a very legitimate use of the word Binua, "orang Binua" literally meaning the people of the country. But it did not appear from enquiries made in many places, that they ever had any distinctive name. The Malays term them "orang-utan" men of the forest, "orang darat liar" wild men of the interior &c. epithets which they consider offensive, and the Malays generally address them as "orang-ulu" people of the interior, or rather of the upper part of the river. This people occupy all the interior of Johore properly so called, or that portion of the ancient kingdom of that name over which the Tamungeng now exercises the rights of royalty. They also possess the interior of the most southerly portion of Pahang. The most definite description of their territory however is, that they occupy the upper branches of the last or most southern system of rivers in the Malay Peninsula, that is of the rivers Johore (the Lingiu and the Sayong) Binut, Pontian, Batu Pahator Rio Formosa (the Simpang Kiri, Pau, and Simrong with their numerous affluents) and Indau (the Anak Indau, Simrong and Made), with the country watered by them. By means of these rivers a constant communication is maintained between the families of the Binua on the two sides of the Peninsula.—*Jour. Ind. Arch. Vol. No. V. Page 246, 1847.*

The lofty Gunong Bermun (which is probably nearly one hundred miles to the north of the Lulumut group) with the mountains which adjoin it, may be considered the central highlands of these tribes. In the ravines and vallies of Gunong Bermun, two of the largest rivers of the Peninsula, the Pahang and the Muar, with their numerous upper tributaries have their source. There also rises the Simujong which unites with the Lingi.

The upper part of these rivers and many of their feeders are occupied by five tribes of aborigines differing somewhat in civilization and language. The Udai (who appear to be the same people who are known to the Binuas of Johore under the name of orang Pago) are found on some of the tributaries of the Muar, as the Segamet, Palungan and Kapi, and in the vicinity of Gunong Ledang. This tribe has less approximated to Malayan habits than the others. The Jakun partially frequent the same territory, the lower part of Palungan, Gannam &c. and extend

northwards and north westward within the British boundaries.

In personal appearance the Binua bear a strong family resemblance to the Malays; and it was remarked of many of them, as was previously done of the Besisi, that the difference was scarcely appreciable so long as they remained at rest and silent.

The round swelling forehead of the Bugis, however, which rises evenly from the cheek bones and gives a distinctive character to their physiognomy, detracts from this resemblance, which appears to be caused mainly by the almost feminine fullness, smoothness, and symmetry of all the outlines, the absence of angular prominences or depressions, and the pleasing softness and simplicity of the expression, all which are wanting in the Malay. It should be added that the Bugis countenance bears an impress of intelligence, feeling, and sometimes, if it does not belie them, of a genial sensibility and imaginativeness. In many cases the Binua face is fat and fleshy, and all the features heavy, but in general, although full and rounded, it is not fat. The greatest breadth is commonly across the cheek bones, but in several instances where the jaws were prominent, the lower parts of the face was broadest.

Many of the Mintira around Gunong Bermun still wear the bark of the tirap, the men using the Chawat, and the women a piece of rude cloth, formed by simply beating the bark, which they wrap round their persons, and which, like the sarong of the Johore females, reaches only from the waist to the knees. The Udai females wear the Chawat like the males.

The only employment at a distance from the ladang which they share with the men, and sometimes pursue by themselves, is angling. Many families have small huts on the bank of the nearest stream where they keep canoes, and men, women and children, usually one in each canoe, are every where met with engaged in this quiet occupation. They have other modes of catching fish. The most common is by small portable traps woven of rattans. Rows of stakes are also used. But the most elaborate engine by which the rivers are sifted of their denizens consists of a large frame work, like the skeleton of a bridge, thrown right across the stream, and at a level some feet higher than the banks so as to be above inundation. A line of stakes is fixed across the bed, an opening being left in the middle. Above this the Binua takes his seat on a small platform, sometimes sheltered by a roof, and suspends a small net in the opening. On this he keeps his eyes intently fixed, and as soon as a fish enters, he raises his net and extracts it. The rivers and streams abound

more detailed account of the country which will follow.

At the period of the visit nearly every man in the country was searching for taban, to which the name of guttah percha, a gum yielded by a different tree, is erroneously applied by Europeans. It is time that an endeavour should be made to avoid these mistakes. We might with as much truth and propriety call an apple a pear. This tree is one of the most common in the forest of Johore. It is not found in the alluvial districts; but in undulating or hilly ground, such as that which occupies the centre of the Peninsula between the Indian and Batu Pahat, it occurs frequently, and in some places abundantly. Wherever he penetrated he found that taban collectors had preceded him. He was much struck by the remarkable uniformity in size of the full grown tabans. They had all perfectly straight trunks, from 60 to 80 feet in height, and from two to three feet in diameter, the great majority being about two and a half feet. The branches are few and small compared with the durian, and have not that tendency to be crooked which adds so much to the beauty of a full grown durian.

The Binua after felling the tree make an incision quite round it from which the milk flows. This is repeated at distances of 6 to 18 inches along the whole trunk. The incision has only the breadth of the parang with which it is made, no bark being removed save the rough superficial coating for an inch or two on each side. Many of the trees which had been felled by Malays instead of a single incision had rings of bark of about an inch in breadth cut out. A Malay woodman who had been employed in different places in procuring the gutta mentioned that this system is always adopted by the Malays. This is in corroboration of what Dr. Oxley has stated on this head in his excellent paper on the taban because in an article on the substance which appeared about the same time in Chambers' Edinburgh Journal, it is said the bark is stripped off the tree. It is to be feared that the method of obtaining the gutta suggested by Dr. Oxley cannot be put in practice. The writer of the article asked both Malays and Binuas in different parts of the country whether they could not procure it without destroying the tree in the same way as they collect minia dammer. But the answer always was that the taban would not run like dammer and many other gittas such as the ca-outchouc. This is probably the fact, because he noticed that on making incisions in growing trees, the milky juice did not flow freely, and rapidly concreted. Its appearance in this state before being boiled is very different from that of the article as imported into Singapore. It has a dry ragged look resembling shreds of bark, and instead

pieces. He frequently saw it in this state when newly brought in from the jungle. Various statements were made as to the produce per tree. Considering that the trees are so nearly of one size, it is surprising that the quantity of *tàbàn* yielded by them differs so much. The extremes mentioned were two catties, and fifty catties, but it is doubtful whether any thing near the latter quantity is ever obtained. Many Binuas who had been engaged for some months in the collections assured him that they had occasionally obtained as much as 18 catties but never more, and that the quantity is commonly nearer 3 to 5 catties than the maximum. The *tàbàn* is noticed at some length because an interest attaches to it at present, and because nearly the whole Binua people for sometime past have been withdrawn by it from their usual pursuits. They are not under any apprehension that it will be extirpated, and smiled at his ignorance on suggesting the probability of its being so. It is only trees arrived at their full growth, or at least at a very considerable age, that repay the labour of felling them and extracting the *gittá*, and those of all inferior ages which they are compelled to leave, will keep up the race. They are no doubt in so far correct, but the effect of thinning the *tàbàn* at the present rate is to reduce the annual supply of seed and young plants. The seeds are eaten by the Binuá, but they do not, like Malays in some countries, as at Siak, extract an edible vegetable tallow from them.

The *sumpitan* is known and is said to be used in some places. The bow and arrow are also known but not used. The Malays have not supplied them with articles so costly and dangerous as fire arms. All the Bermun tribes use the *sumpitan* and poisoned darts. Their *sumpitan* is a light and neat instrument and differs from that of the Dyak which is a piece of wood bored. That of the Bermun tribes (*timiang*) consists of two bambus seven feet in length one enclosed within the other. The external one, which is merely for strength and ornament, is about three-fourths of an inch in diameter, and neatly carved for about a foot at each end and in the middle. To prevent it splitting the fibrous bark of the *triáp* is bound round about 6 inches of the extremity and a coating of dammar placed over it. The internal tube, which is the proper *sumpitan*, is of the same length with the case but only three-fifths of an inch in diameter. It is composed of two pieces of bambu, united by a piece of 8 inches long, which embraces the ends tightly at the junction. The bambu used (the *bulu timiang*) is very light and fine grained.

The arrows (*damák*) are small darts made of the stem of the *birtam* leaf, 10 inches in length, and one sixteenth of an inch in diameter at the base, from which they gradually taper to a very fine sharp point. The base is inserted

into a cone of *káyu tutú* (which is very porous and light) about an inch in length and one-third of an inch in diameter at its base. The point of the dart is dipped for about five-sixths of an inch in *ipoh*. This is made by taking *akar ipoh*, *batang ipoh* (or *kyas*), *limes*, and *tuba*, which are bruised, boiled and strained. To this arsenic is added. Other substances, such as *páchet*, *jimardès*, *máilye*, and *gadong*, are also sometimes added. The preparation, called *ipoh*, has the colour and consistency of *chandu*. An incision is made round the dart above the *ipoh* so as to ensure its breaking off and remaining in the wound.

Each dart is kept ready for use in a case of bambu about one-fourth of an inch in diameter. Fifty of these cases are laid side by side and united by strings. They are then rolled up and inserted into a case also made of bambu, and which has a neat lid of *jalutong*. The same case contains a quantity of *barok* (a very light, spongy substance, also used as tinder) extracted from a tree called *runout*. After inserting the dart into the *sumpitan* a little *barok* is introduced. When the Binua blows into the tube, it is pressed against the base of the *kaya tutucone*, and prevents any of the air escaping between it and the sides. In shooting, the *sumpitan* is held firm by both hands being tightly clasped over its end, which is inserted into a handle.

*Government.*—The boundary between Pahang and Johore intersects the country of the Binua, the whole of the *Anak Indau*, and the lower part of the *Sinrong* being in Pahang, and all the other rivers, including the *Made*, on which they are found, appertaining to Johore. The authority of the *Bindahara* and the *Tamungong* is little more than nominal, the affairs of the Binua being entirely administered by their own chiefs, each of whom has a definite territorial jurisdiction.

*Religion and Traditional Origin.*—So far as he was able to ascertain, the Bermun tribes have no idea of a Supreme Deity, and he took it for granted that he would find the Binua equally atheistic. His surprise was therefore great when he discovered that they have a simple, and, to a certain extent, rational theology. They believe in the existence of one God, *Pirman*, who made the world and every thing that is visible, and at whose will all things continue to have their being. *Pirman* dwells above the sky, and is invisible. Intermediate between *Pirman* and the human race are the *Jin*,—the most powerful of whom as the *Jin Bumi* or Earth Spirit, who is *Pirman's* minister. He dwells on the earth, feeding on the lives of men and of all other living things. It is the *Jin Bumi* who sends all kinds of sickness and causes death; but this power is entirely derived from *Pirman*. Each species of tree has a *Jin*. The rivers have a spiritual life, but it is that of the *Jin Bumi*,

who haunts them with his power. The mountains are also animated by him. He does not, therefore, appear to be entirely a personification of the destructive power of nature, but to be, to some extent, identified with its living force also. There is no religious worship, but to avert death recourse is had in sickness to a Poyang, no other person being supposed to have the right of imploring mercy from Pirman. The Poyangs are an order of men combining the functions of priest, physician and sorcerer.

A complete parallel exists between the religions of the Dyaks, Binuas and Battas, and the elaborate and luxuriant imaginations with which the primary and essential ideas have been overrun by the first, and the simplicity in which they have been retained by the second, are directly referable to the difference in the characters and developments of the two people. The primitive religion of the Archipelago, a variety of the Shamanism, which probably prevailed before Buddhism over all eastern Asia, which lingers around the mosque, and has not entirely faded away in the West in the presence of nearly 2000 years of Christianity, is still the essential belief of the Dyak, the Binua and the Batta. In it they repose a practical faith. By it they seek to defend themselves from diseases and other misfortunes, to secure the ministry of good spirits, and counteract the maleficence of evil ones. It is one of the living springs of their habitual thoughts and actions, and as such remains a prominent link between the extreme south and the north of Eastern Asia.

Amongst the Bermun tribes we recognize a pure Shamanism with its accompanying charms and talismans; a living faith fresh from the ancient days of eastern and middle Asia, preserving its pristine vigour and simplicity in the nineteenth century, untouched by the Buddhistic deluge which has passed over the vast south eastern regions, and sent so many waves to different parts of the Archipelago; and resisting the pressure of the Islamism which surrounds it.

The Poyang and Pawang of the Bermun tribes, the Poyang of the Binua, the Blians of the Dyaks, and Dato and the SiBasso of the Battas, are all the shaman, the priest, wizard, physician, in different shapes.

In the course of this paper there has been occasion to compare or contrast the aborigines of the south of the peninsula with the Malays, the Battas and the Dyaks.

The character of the Binua, the Dyak and the Batta is essentially the same, and may still be recognized in the Malay. The Binua has less development of intellect, and less corruption of the passions.

The Battas and Dyaks have long outgrown the close pressure of nature, and agglomerated

into social masses in which the passions have fermented, and the intellect and imagination been quickened. But these social masses have been small, nature has not been driven back on all sides as in the plains and slopes of Menangkabau. Hence both the Batta and most of the Dyaks still preserve the Binua character at bottom; but, unlike the Binua, they have elaborated their superstitions and their social habits, and have acquired some vicious propensities, such as gambling, which the Battas carry to a mad excess, and the unnatural customs of head hunting and man eating, which are only more startling illustrations of the universal truth, that, without a religion like Christianity, which does not stop at precepts and doctrines but spiritualizes the very springs of action, and fills the soul with the divine idea of the world, virtues and vices, and particularly those which are national, may dwell together in harmony. It is undeniable that the Battas as a people have a greater prevalence of social virtues than most European nations. Truth, honesty, hospitality, benevolence, chastity, absence of private crimes, exist with cannibalism.—*Jour. of the Indian Archipelago, page 293. No. V. November 1847.*

(244) BIRDLIME. The best is prepared from the outer covering of the fruit and tender twigs and bark of the Jack. It is prepared from the middle bark of the holly in Europe by boiling seven or eight hours in water, then laid in heaps on the moist ground to ferment, with stones over it, to press it down till it passes into a mucilaginous state, then pounded, washed and kneaded till free from extraneous matter and kept for four days in pots to ferment and purify itself when it is fit for use.—*Rohde M.S.S.*

(245) BIRDS. The birds of India are scarcely less beautiful than numerous. Perhaps the choicest of them all are those of the Himalayan pheasant tribe, birds distinguished for their very graceful and rich plumage. The Himalayan bustard is remarkable for its form and varied colour. Peacocks, eagles, falcons, vultures, kites, cranes, wild geese, wild fowl, snipes, bustards, parrots, and paroquets, the latter in every conceivable variety, abound in all parts at various seasons. *Capper.*—In England, on the return of spring,

“Every copse

Deep tangled, tree irregular, and bush  
Bending with dewy moisture o’er the heads  
Of the coy quiristers that lodge within,  
Are prodigal of harmony,

but, in the tropics generally, there are few Europeans who will dare the sun to search for the beauties of Nature and comparatively little is known of the songs of birds. Few of us can say with the rustic poet Clare.

## BIRDS.

"I've often tried when tending sheep or cow,  
With bits of grass and peels of oaten straw,  
To whistle like the birds. The thrush would start  
To hear her song of praise and fly away;  
The black bird never cared, but sang again;  
The nightingale's pure song I could not try,  
And when the thrush would mock her song, she  
paused,  
And sang another song no bird could do.  
She sang when all were done, and beat them all."

The nidification of Indian birds has been noticed by Capt. Thomas Hutton, F. G. and (communicated by E. Blyth, Esq.) Capt. Tickell.

Captain Tickell made a praiseworthy beginning in the April number of the Journal of the Asiatic Society for 1848, to dispel the darkness that has hitherto hung over our knowledge of this portion of the history of the Birds of India, and Captain Hutton thought it advisable, being in possession of a few facts bearing on the subject, to follow in the path Captain Tickell had so well pointed out.

### No. 1 "*Haliaetus Macei*, Cuv."

I notice, he says, this species because Captain Tickell has remarked that it "never makes the slightest attempt at defending its nest,—a striking contrast to the marvellous tales we read of, concerning the Golden Eagle in the Highlands of Scotland, &c." This remark is correct only as long as there are eggs in the nest, for no sooner are these hatched than the temper of the bird becomes wholly changed, and it will then defend its young with fierceness and determination. The nests I have repeatedly found and robbed, both on the banks of the Ganges and of the Sutledge, and in all cases where they contained only eggs, not the least show of resistance was made,—the old birds either sailing with a loud querulous cry, or sullenly remaining on an adjacent tree, watching the robbery that was going on. On one occasion, however, I met with a very different reception, when my servant was attacked with an unexpected ferocity from which nothing but my gun could have saved him. The circumstance occurred in January 1832 when on my way up the country. The nest was placed near the summit of a tree growing on one of the Colgong rocks in the middle of the Ganges, and contained two half-fledged young ones. The old birds offered a most determined resistance, and without the aid of fire-arms we should decidedly have been defeated, as they dashed fiercely and fearlessly at the man in the tree—who prayed hard to be allowed to descend, and was only kept at his post by the promise of reward and fear of the cudgel. At first we had to contend with the female only, but after one or two rapid stoops and dashes at the robber's head, which he avoided by robbing under the nest, finding she could make no impression, she suddenly uttered a shrill cry, which was responded

## BIRDS.

to in the distance and in an instant after, her mate was seen swiftly gliding to her aid from the opposite bank of the river. The two then charged together towards the nest with the rage and fierceness of despair, and so terrified the man in the tree, hampered as he was with the young ones, that had I not fired at and wounded the Eagle as they advanced, they would assuredly have hurled him into the river. In this manner, however after repeated attempts to come to the rescue, we managed at last to drive off, and secure the booty. At the end of 5 weeks the young ones exhibited as nearly as possible the plumage of the bird figured by Hardwicke and Gray as "*H. lineatus*."

### No. 2.—"*Ephialtes scops*," (L.):

*E. spilocephalus*, Blyth, (a large specimen in immature plumage):

*Scops pennata*, Hodgson (Grey variety):

*Sc. sumia*, Hodgson (rufous variety).

This species occurs on the Himalaya in the neighbourhood of Mussooree, at an elevation of about 5,000 feet, and nidicates in hollow trees, laying, 3 pure white eggs, of a rounded form, on the rotten wood, without any preparation of a nest. Diameter of egg  $1\frac{3}{8}$  x 1 ins. The nest was found on the 19th March.

In the 169 number of the J. A. S. for 1846. Mr. Blyth has named and described this species as "*Ephialtes spilocephalus*," giving "*Noctua auribarbis*" and "*Athene badia*" of Hodgson, as doubtful synonyms.

In plumage and aigrettes the bird is to all appearance a *Scops* or *Ephialtes*,—but the wing is that of *Noctua* or *Athene*, having the 14th and 15th feathers longest—whereas in *Scops*, as laid down by Mr. Hodgson in J. A. S. No. 65 of 1827,—the 3d and 4th are longest. Mr. Gray, in his Catalogue of the collection presented by Mr. Hodgson to the British Museum, gives "*N. auribarbis*" of that naturalist as a synonyme of "*Athene cuculoides*" of Vigors,—but it seems scarcely probable that Mr. Hodgson would have placed his "*auribarbis*" in the genus "*Noctua*." If the characters of the wing rendered it improper so to place it. Had such however been the case, the necessity for coining a new specific name is not apparent. This handsome little species appears to agree neither with *Scops* nor *Athene*,—for while the wing belongs to the latter genus,—the plumage, aigrettes and nude feet refer it to the former. It would now seem however that neither *Scops* nor *Ephialtes* can stand for a genus of owls,—the first being otherwise employed in Ornithology,—while the latter is a genus in Entomology instituted by Gravenhorst. (Vide Mat. Lib. Introd. Entom.) It is therefore necessary to form a genus of these owls.

### No. 3.—"*Athene Brodiei*," (Burlon.)

This pretty little species is exceedingly common in the Himalayas in the neighbourhood of

Mussooree and Simla, and may be heard at nightfall uttering its monotonous but not unmusical whistle of two notes of times repeated. Like the last, it nidificates in hollow trees without any preparation of a nest. On the 11th May, he found 3 young ones and an egg just ready to hatch in a hole of a wild Cherry tree. The egg was nearly round and pure white, but being broken he could take no measurement of it. The young ones were clothed in a soft and pure white down.

In both these instances, namely, "*A. nudipes*" and "*A. Brodiei*," the old females remained in the holes while they cut into the trees, and allowed themselves to be captured.

No. 4.—"*Caprimulgus albonotatus*," Tickell. *C. Nipalensis*, Hodgson, (Gray's Zool. Misc.)

Of this species, which is a summer visitor at Mussooree, Captain Tickell says, the eggs are "fleshy clay colour, sprinkled with patches of darker brownish red: females, paler and redder." He took 2 eggs of this bird at an elevation of 5,000 feet, on the 19th April, from the bare ground beneath bushes on the side of a hill, the colour being a rich cream white with darker blotches of reddish brown or clay colour. Of one the diameter was  $1\frac{1}{4} + \frac{7}{8}$  inches, the other was somewhat smaller.

No. 5.—"*Garrulus lanceolatus*," Vigors. *G. gularis* et *G. Vigorii* (Gray's Ill. Ind. Zool.)

This is one of the commonest birds in the Hills, usually appearing, except in the breeding season, in small parties of 5 or 6, most probably comprising a family. It breeds in May and June, placing the nest sometimes on the branch of a tall oak tree (*Quercus incana*); at other times in a thick bush. It is composed of a foundation of twigs, and lined with fine roots of grass, &c., mixed with the long black fibres of ferns and mosses which hang upon the forest trees, and have much the appearance of black horse hair; the nest is cup-shaped, rather shallow loosely put together, circular and about  $4\frac{1}{2}$  inches in diameter. The eggs are sometimes 3, sometimes 4 in number, of a greenish stone-gray, freckled chiefly at the larger end with dusky,—and a few black hairlike streaks, which are not always present; they vary also in the amount of dusky freckling at the larger end. Shape ordinary. The nestling bird is devoid of the lanceolate markings on the throat, and in this stage is the "*Garrulus Vigorsii*" of Hardwicke and Grey.—"*Bunsareah*" of hillmen.

No. 6.—"*Garulax albogularis*," (Gould.)

*Cinclosoma albigula*, Hodgson.

Is very common at Mussooree at all seasons and appears in large flocks of several families united. It breeds in April and May,—placing the nest in the forks of young oaks and other trees about 7 to 8 feet from the ground, though

climbing plants. It is sometimes composed externally almost entirely of such woody tendrils intermixed with a few other twigs, and lined with black hair—like fibres of mosses and lichens; at other times it is externally composed of coarse dry grasses, and leaves of different kinds, of orchis, and lined with fibres; the materials varying with the locality. Unlike the eggs of *Crateropus*, which are stated to be white,—in this species they are of a deep and beautiful green, shining as if recently varnished, and 3 in number. In shape they taper somewhat suddenly to the smaller end, which may almost be termed, obtusely pointed; the diameter  $1\frac{1}{8} + \frac{1}{8}$  inches. The usual number of eggs is three, though they vary sometimes to one or two,—but only on one occasion out of more than a dozen, had he found four eggs. The old bird will remain on the nest until almost within reach of the hand.

No. 7.—"*Trochalopteron ? rufigularis*." (Gray's Catalogue.)

*Crateropus rufimentum*, (Hodgson.)

This species differs from the last in not congregating into large and noisy flocks, but appearing usually, according to his observation in pairs. It breeds in May, in which month he took a nest at about 6,500 feet, in a retired and wooded glen; it was composed of small twigs externally, and lined with the fine black fibres of lichens, like the preceeding. The nest was placed on a horizontal bough about 7 feet from the ground, and contained 3 pure white eggs. Diameter  $1\frac{1}{8} + \frac{1}{8}$ , and shape ordinary. The stomach of the old bird contained sand, seeds, and the remains of wasps.

No. 8.—"*Trochalopteron ? setifer*." (Hodgson and Gray, Zool. Misc.)

*Cinclosoma setifer*, Hodgson.

*C. lineatum*, Vigors?

If the colour of the eggs affords any generic character, this and the foregoing species cannot well rank together, for while in that the eggs are pure white, as in *Crateropus* in this they are pale greenish blue (like those of "*Acridotheres tristis*."\*) The nest is loosely and rather slovenly constructed of coarse dry grass and stalks externally lined sometimes with fine grass, sometimes with fine roots. It is placed near the ground in the midst of some thick low bush,—or on the side of a bank amidst over hanging coarse grass, and not unfrequently in exposed and well frequented places. The eggs are 3 in number, and in shape and size exceedingly variable, being sometimes of an ordinary oval—at others nearly round. Diameter varying,— $1\frac{3}{8} \times \frac{1}{8}$ ; or  $1 \times \frac{1}{8}$ ; or  $\frac{1}{8} + \frac{1}{8}$ . The most usual measurement however is the second one, or  $1 \times \frac{1}{8}$  inches.

In these three species, which have sometimes

points both of similarity and dissimilarity, in their habits and manners.

In the number of eggs they agree, and there is a general similitude in the construction of the nest, more so between the two first—less so between them and the last; in the colour of the eggs they all differ very materially; the first congregates into large and noisy flocks,—turning up the dead leaves and screaming and chattering together in most discordant concert. The second is most usually in pairs—sometimes in a family of 4 or 5; the last in pairs or family of 4 or 5, and to be seen under every bush. Its mode of flight and its note are totally unlike the other two. Any one observing the birds in their native haunts, could not fail to perceive that *G. albogularis* and *G. leucolophus* are allied in manners, voice and habits; that *G. rufigularis*, *G. erythrocephalus* and *G. variegatus* are likewise allied,—and that *Trochaloxyron setifer vel lineatum* stands distinct from all; the three forming distinct sections of the same group.\*

No. 9.—“*Acridotheres griseus*,” (Horsfield.)  
*Maina cristalloides*, Hodgson.

This is a summer visitor in the hills, and is common at Mussooree during that season, but it does not appear to visit Simla, although it is to be found in some of the valleys below it to the south. It breeds at Mussooree in May and June, selecting holes in the forest trees, generally large oaks, which it lines with dry grass and feathers;—the eggs are from 3 to 5, of a pale greenish blue; shape ordinary, but somewhat inclined to taper to the smaller end;—diameter  $1\frac{3}{16} + \frac{1}{16}$  inches; or  $1\frac{2}{16} + \frac{1}{16}$  inches. This species usually arrives from the valley of the Doon about the middle of March; and until they begin to sit on their eggs, they congregate every evening into small flocks and roost together in trees near houses; in the morning they separate for the day into pairs and proceed with the building of nests or laying of eggs. After the young are hatched and well able to fly, all betake themselves to the Doon in July.

No. 10.—“*Acridotheres tristis*,” (Linn ?)

This too is a summer visitor in the hills, arriving with the preceding species. The colour and number of eggs are also the same. It is curious however to observe that while Mr. Blyth and Captain Tickell state, that it builds in “out-houses, verandas and trees,” in which last, according to the latter gentleman, the nest is composed of “twigs and grass within,”—with us in the mountains its habits are precisely those of *A. griseus* and as with it, the whole of a tree is selected and lined with wild grass and feathers;—on no occasion had he ever seen a nest made on the branches of a tree, and only once in any place except the hollows of large oaks; the exception being in the chimney of his house, which the stupid had evidently mistaken for a hollow tree, and

seemed to be amazed that all the grass and feathers dropped into it invariably fell to the bottom, at last it contrived to place some grass on a projecting brick. Can this difference betoken a distinction in species? He is inclined to believe it for why in the plains should a nest be constructed among the open branches of trees,\*—while in the mountains it is constructed within their hollow trunks? If distinct, it will, he imagines, bear Mr. Hodgson's ill-constructed name of *A. tristoides*.”

No. 11.—“*Corvus culminatus*,” Sykes.

[*C. orientalis*, Eversman.]

Occurs at Mussooree throughout the year, and is very destructive to young fowls and pigeons; it breeds in May and June, and selects a tall tree, near a house or village, on which to build its nest, which is composed externally of dried sticks and twigs, and lined with grass and hair, which latter material it will pick from the backs of horses and cows,—or from skins of animals laid out to dry. He had skins of the Surrow (*Nemorhædus thar*) nearly destroyed from their depredations. The eggs are 3 or 4 in number and of a dull green, thickly spotted over with long and sometimes confluent spots and dashes of dusky brown or blackish. Diameter  $1\frac{2}{8} + 1$  inch.

No. 12.—“*Saroglossa spiloptera*,” Hodgson.

*Lamprotornis spilopterus*, Vigors.

This species arrives in the hills about the middle of April, in small parties of 5 or 6, but it does not appear to ascend above 5,500 to 6,000 feet and is therefore more properly an inhabitant of the warm valleys. He does not remember seeing it at Mussooree, which is 6,500 to 7,000 feet,—although at 5,200 feet on the same range, it is abundant during summer. Its note and flight are very much those of the Starling (*Sturnus vulgaris*), and it delights to take a short and rapid flight and return twittering to perch on the very summit of the forest trees; He had never seen it on the ground, and its food appears to consist of berries. Like their two species of *Acridotheres*, it nidificates in the holes of trees, lining the cavity with bits of leaves, cut by itself; the eggs are usually 3, or sometimes 4 or 5, of a delicate pale sea green, speckled with blood like stains, which sometimes tend to form a ring near the larger end—shape oval, somewhat tapering; diameter  $1\frac{1}{8} + \frac{1}{16}$  inches.

No. 13.—“*Pomatorhinus erythrogenys*,” Vigors.

*P. ferrugilatus*, Hodgson.

Common from 3,500 feet up to 10,000 feet; always in pairs, turning up the dead leaves on copse-wood covered banks, uttering a loud whistle, answering and calling each other. It breeds in April constructing its nest on the ground, of coarse dry grasses and leaf stalks of walnut trees &c.; covered with a dome-shaped roof so nicely blended with the fallen leaves and withered grass—

es among which it is placed as to be almost undistinguishable from them. The eggs are 3 in number and pure white; diameter  $1\frac{2}{8} + \frac{1}{8}$  inches of an ordinary oval shape. When disturbed, the bird sprung along the ground with long bounding hops so quickly, that from its motions and the appearance of the nest, he was led to believe it a species of rat. The nest is placed in a slight hollow, probably formed by the bird itself.

No. 14.—“*Pycnonotus leucogenys*,” Gray.

*Ixos leucogenys*, Hodgson and Gray.

*Brachypus leucogenys*, (Hardw., Gray. Ill. Ind. Zool.

Common in the Doon all the year, and in the hills during the summer. It breeds in April and May. The nest is neat and cup-shaped, placed in the forks of bushes or pollard trees, and is composed externally of the dried stalks of “Forget-me-not,”—lined with fine grass stalks; eggs 3 or 4, rosy or faint purplish white, thickly sprinkled with specks and spots of darker rufescent purple or claret colour; diameter  $\frac{1}{8} + \frac{1}{8}$  inches; diameter of nest  $2\frac{1}{2}$  inches and  $1\frac{1}{2}$  inch deep. Sometimes the outside of the nest is composed of fine dried stalks of woody plants, whose roughness causes them to adhere together.

No. 15.—“*Hypsipetes psaroides*,” Vigors.

Exceedingly common at Mussooree in large flocks during the winter and spring. In the latter season, when the *Rhododendron arboreum* is covered with its branches of deep crimson flowers, these birds may be seen thrusting their beaks into every flower in search of insects and nectar, and the forehead is in consequence then generally covered with the pollen and sweets derived from the flowers. It pairs in April and appears fond of the wild mulberries and other forest berries which abound in some of the glens. In March at an elevation of 5,000 feet, he saw them feeding on the wild cherries. They breed during April, May and June, making a rather neat cup-shaped nest, which is usually placed in the bifurcation of a horizontal branch of some tall tree; the bottom of it is composed of thin dead leaves and dried grasses, and the sides of fine woody stalks of plants, such as those used by *Pycnonotus leucogenys*, and they are well plastered over externally with spiders’ webs; the lining is sometimes of very fine tendrils, at other times of dry grasses, fibrous lichens and thin shavings of the bark of trees, left by the wood-cutters. He had one nest, however, which is externally formed of green moss with a few dry stalks, and the spider’s webs instead of being plastered all over the outside, are merely used to bind the nest to the small branches among which it is placed. The lining is of bark shavings, dry grasses, black fibrous lichens and a few fine seed stalks of grasses. The diameter of the nest is  $2\frac{3}{4}$  inches; and  $1\frac{1}{2}$  inch deep. The eggs are usually 3 in number, of a rosy or purplish white sprinkled over rather numerously with deep claret or

rufescent purple specks and spots. In colour and distribution of spots there is great variations, sometimes the rufous and sometimes the purple spots prevailing; sometimes the spots are mere specks and freckles; sometimes large and forming blotches; in some the spots are wide apart, in others they are nearly and sometimes in places quite confluent; while from one nest the eggs were white, with widely dispersed dark purple spots, and dull indistinct ones appearing under the shell. In all, the spots are more crowded at the larger end. Diameter varying from  $1\frac{1}{8}$  inches, to  $1\frac{7}{8} + \frac{1}{8}$  inches. “Bunbukri,” of hill men, from a fancied resemblance of one of its cries to that of a goat.

No. 16.—“*Treron sphenurus*,” (Vigors.)

*Vinago sphenura*, Vigors.

*Ptilonopus macronotus et tinturoides*. (Hodg., Gray.)

*Treron cantillans*, Blyth, (the caged bird, moulted in confinement)

This species which is the “Kookla” of the natives arrives in the neighbourhood of Mussooree in the beginning of April, and remains during the summer to breed; it is usually silent during the height of the monsoon, but may occasionally be heard on a bright day. It is probable that it migrates to the eastward on leaving Mussooree, as it does not winter in the Doon, nor does it occur there even in summer, being apparently a true hill species. In confinement it loses or does not put on the maroon mantle which ornaments the wild bird, and the plumage assumes a dull greenish ashy hue, in which state it is the *T. cantillans* of Mr. Blyth. The nest is composed of dried twigs, and the eggs are usually 2 in number and pure white, and more gracefully ovate than those of *Turtur risorius*. Diameter  $1\frac{2}{8} + \frac{1}{8}$  inches. The breeding season is from the end of April till the latter end of June; the nest a slight platform, usually placed in high forest trees. In October they collect into small flocks of 6 or 8, and quit the neighbourhood of Mussooree; where do they then go to? The female differs from the male, in the absence of the fulvous colour of the top of the head and breast, and in wanting the beautiful maroon colour on the mantle and lesser wing coverts; the greater wing coverts are also more broadly edged with pale yellow. Mr. Blyth states of this species that it is distinguishable from *T. nipalensis*, (Hodgson,) “by having but a slight pale yellow margin to only the great coverts of the wing;” whereas in both male and female, the great coverts, tertiaries, and primaries are edged with that colour, although on the latter it amounts to a mere thread. These birds are very fond of the wild mulberries and other forest fruits. Gould, in his ‘Century of birds,’ appears to think the species is only found far within the mountains, whereas it occurs on the outer or southernmost range overhanging

## BIRDS.

the Doon, from an elevation of 4,000 feet, probably to the snows. The Huryal, or *T. phoenicopterus*, lays a similar egg but is confined to the plains, ranging up to the base of the mountains but never ascending them.

No. 17.—“*Turtur risorius*” Selby.

*Columba risoria*, Linn.

*T. douraca*, Hodg. Gray.

This is common in the Doon at all seasons, only visits Mussooree during summer, arriving on the hills about the end of March and returning to the plains in October. It breeds in April, May and June, making a loose platform nest of dried twigs with a few roots within; the eggs are 2 in number and pure white; diameter  $1\frac{3}{5} + \frac{1}{8}$  inches.

No. 18.—“*Turtur orientalis*,” (Latham.)

*Columba meena*, Sykes.

*C. agricola*, Tickell.

*C. pulchrata*, Hodg.

*C. ferrago*, Eversmann.

This also is a mere summer visitor at Mussooree, where it arrives early in April, when every wood resounds with its deep-toned cooing;—it is not found lower than, 6,000 feet there,—and departs in October. At Mussooree it breeds in May, making a platform nest on tall forest trees; the eggs are 2 and pure white; diameter  $1\frac{4}{6} + \frac{1}{8}$  inches.

No. 19.—“*Turtur suratensis*,” (Gm.)

*T. vitticollis*, Hodg.

*Columba tigrina*, Temm.

Abundant in the Doon, and arrives in the hills in the end of March, leaving again in the autumn. It breeds at about 5,000 feet and lays 2 white eggs,—diameter 1 inch  $+ \frac{1}{8}$ . Captain Tickell says, “eggs 2 to 16;” He had never seen more than 2 in any nest.

No. 20.—*Turtur senegalensis*, (Linn.)

*C. cambaiensis*, Gm.

Arrives at 5,000 feet like the others about March or April, departing again in Autumn;—its eggs are 2, and pure white;—diameter 1 inch  $+ \frac{1}{8}$ . He had observed in this, as well as in the foregoing different species of *Turtur*, a tendency in the eggs to become suddenly pointed, or slightly nipple-shaped.

Notes on the Nidification of Indian Birds. Captain Thomas Hutton.—*F. G. S. in Ben. A. S. Journ.* (Continued from No. 193 for July 1848.)

No. 21.—“*Psilorhinus occipitalis*” (Blyth, J. A. S. XV. 27.)

“*Pica erythrorhyncha*” (Gould’s Century.)

“*Psilorhinus albicapillus*.” (Blyth nestling plumage.)

This species occurs at Mussooree throughout the year, collecting into small parties of 4 to 6 during winter. It breeds at an elevation of 5,000 feet in May and June, making a loose platform nest, externally lined with roots.

## BIRDS.

The eggs are from 3 to 5, of a dull greenish ash-grey, blotched and speckled with brown dashes, confluent at the larger end. Diameter  $1\frac{1}{8} + \frac{1}{8}$  inches. The ends nearly equal in size. The nest is built on trees sometimes high up; at others about 8 or 10 feet from the ground.

The “*Psilorhinus albicapillus*” of Mr. Blyth, is nothing more than the nestling of this species as he had fully ascertained by robbing several nests,—the plumage of the young birds agreeing exactly with his published description.

No. 22.—“*Dendrocitta sinensis*.” (Gray.)

*Crypsirina sinensis*. (Hodg. Gray.)

*Pica sinensis*. (Gray.)

*Corvus sinensis*. (Daud.)

Occurs abundantly about 5,000 feet during summer, more sparingly at greater elevations,—and in the winter it leaves the mountains for the Doon. It breeds in May, on the 27th of which month he took one nest with three eggs and another with 3 young ones. The nest is like that of *Psilorhinus occipitalis*, being composed externally of twigs and lined with finer materials according to the situation,—one nest taken in a deep glen by the side of a stream was lined with the long fibrous leaves of “mare’s tail” which grew abundantly by the waters edge; another taken much higher on the hill side and away from the water, was lined with tendrils and fine roots. The nest is placed rather low, generally about 8 or 10 feet from the ground, sometimes at the extremity of a horizontal branch, sometimes in the forks of young bushy oaks. The eggs somewhat resemble those of the foregoing species, but are paler and less spotted, being of a dull greenish ash, with brown blotches and spots somewhat thickly clustered at the larger end. Diameter  $1\frac{3}{8} + \frac{1}{8}$  inches. Shape ordinary.

No. 23.—“*Geocichla citrina*.” (Blyth.)

*Petrocossyphus citrinus*. (Gray’s Cat.)

*Turdus citrinus*. (Lath.)

*P. pelodes*. (Hodg.) Young.

Arrives at an elevation of 5,000 feet about the end of May and returns to the plains in autumn, it breeds in June, placing the nest in the forky branches of lofty trees, such as oaks and wild cherry, externally it is sometimes composed of coarse dry grasses somewhat neatly interwoven on the sides,—but hanging down in long straggling ends from the bottom. Within this is a layer of green moss and another of fine dry woody stalks of small plants and a scanty lining at the bottom of fine roots. The eggs are 3 to 4 in number, pale greenish freckled with rufous, the spots of that colour confluent and forming a patch at the larger end. Diameter  $1\frac{3}{8} + \frac{1}{8}$  inches. Somewhat gibbous at the larger end.

No. 24.—“*Geocichla unicolor*.”

*Turdus unicolor*. (Tickell and Gould.)

*Petrocincla homochroa* (Hodg. Gray.)

*Petrocossyphus unicolor*. (Gray’s Cat.)

## BIRDS OF SOUTHERN ASIA.

This bird arrives in the hills up to 7,000 feet, and probably higher, about the end of March the first being heard (in the year 1848) on the 26th of that month at 5,000 feet. Every morning and evening it may be heard far and near, pouring forth a short but pleasing song from the very summits of the forest trees. It is a summer visitor only, returning to the plains in early autumn. It breeds in May and June, laying 3 or 4 eggs of a dull greenish white freckled, blotched and spotted with rufous, sometimes closely,—sometimes widely distributed.

The nest is neatly made of green moss and roots, lined with finer roots, and placed usually against the body of the trees from whence spring one or two twigs sometimes placed upon the broad surface of a thick horizontal branch or on a projecting knob. The diameter of egg— $1\frac{1}{8} \times \frac{1}{8}$  inches, varying a little; shape sometimes ordinary ovate, at others more rounded at the smaller end. When shot, the crop usually contained the half ripe berries of a species of laurel (*L. lanceolatus*?)

The following is the description of a male, shot while singing on the topmost branch of an oak tree (*Quercus incana*.)

Male.—Bill yellow, as also the rim of the eyelid, gape, inside of mouth and the legs. Iris brown. Length inches. Wing from bend  $4\frac{3}{4}$  inches. Above uniform pale slate-grey; throat, breast, and sides ash colour, the former palest and nearly white on the chin. Belly and under tail coverts pure white; under wing coverts bright ferruginous. Nails yellow, length of bill to gape  $1\frac{3}{8}$  inches. Tarse  $1\frac{1}{8}$  inches.

Female. Bill wax yellow with dusky about the nostrils; legs and feet wax yellow; Iris brown; length 9 inches; wing from bend  $4\frac{3}{4}$  inches; bill to gape  $1\frac{3}{8}$  inches; to forehead  $\frac{7}{8}$  inches. Above uniform dark ashy gray; chin and throat pale cinereous, bordered by a dark stripe descending from the base of lower mandible, between which the feathers are longitudinally dashed with dark centres, breast and sides ashy tinged with fulvous; belly, vent and lower tail coverts white; under wing coverts bright ferruginous; ear coverts ashy with pale shafts.

The nestling is above like the female, but beneath the throat and chin are purer white in some; in others with a rufous tinge but no spots between the stripes descending from the base of lower mandible, and the breast much spotted with brown; scapularies and greater wing coverts tipped with triangular fulvous spots ascending through the shafts of the feathers. This during the summer months is one of the commonest birds in the hills, especially about 5,000 feet, where their nests are numerous

No. 25.—“*Myophonus Temminckii*.” (Vigors, Gould.)

*M. metallicus*. (Hodg.)

On the 16th June last, at 5,000 feet, I shot

bird, each containing 3 eggs, and another one containing three nearly fledged young ones. The nest bears a strong resemblance to that of the *Geocichla* above noticed, but is much more solid, being composed of a thick bed of green moss externally lined first with long black fibrous lichens, and then with fine roots. Externally the nest is  $3\frac{1}{2}$  inches deep, but within only  $2\frac{1}{2}$  inches; the diameter about  $4\frac{3}{4}$  inches and the thickness of the outer or exposed side is 2 inches.

The eggs are 3 in number of a greenish ashy, freckled with minute roseate specks, which become confluent and form a patch at the larger end; shape ordinarily and rather gracefully, ovate; diameter  $1\frac{6}{8} \times \frac{1}{8}$  inches.

The elevation at which the nests were found was from 4,000 to 4,500 feet, but the bird is common, except during the breeding season, at all elevations up to the snows, and in the winter it extends its range down into the Doon. In the breeding season it is found chiefly in the glens, in the retired depths of which it constructs its nest, it never, like the Thrushes and *Geocichla*, builds in trees or bushes but selects some high towering and almost inaccessible rock forming the side of a deep glen, on the projecting ledges of which, or in the holes from which small boulders have fallen, it constructs its nest; and where unless when assailed by man, it rears its young in safety, secure alike from the howling blast and the attacks of wild animals. It is known to the natives by the name of “*Kuljeet*” and to Europeans as the “Hill Black bird.”

The situation in which the nest is placed is quite unlike that of any other of the Hill Thrushes with which he was acquainted, and the habits of the bird render it far more deserving of the name of *Petrocossyphus* or “Rock black-bird” than those to which, in the Catalogue of Mr. Hodgson’s Collection, Mr. Gray has assigned that name. Indeed, as applied to the two preceding species, it is altogether a misnomer, for they are, in the first place—not Blackbirds or *Merulae*, as the Greek word “*Cossyphus*” implies,—and in the second place, they are not Rock lovers at all, but true forest birds, building in trees and taking their food upon the ground, where they find it in berries and insects among the withered leaves which they expertly turn over with their beaks, and hence the reason why the beak is almost invariably clogged with mud or other dirt. He had never seen these *Geocichlae* except in woods,—whereas “*Myophonus Temminckii*” is as often found in open rocky spots on the skirts of the forest, as among the woods, loving to jump upon some stone or rocky pinnacle from whence he sends forth a sort of choking chattering song, if such it can be called—or with a jerk of the tail, hops away with a loud musical whistle, very much after the man-

## BIRDS OF SOUTHERN ASIA.

On the southern side of the range at Jerrepancee, elevation about 5,000 feet, the forest is open and scattered among immense bare blocks of stone;—on the northern side of the same range, the forest is dense and contains much underwood. It is remarkable that while the *Geocichla* above noticed, are strictly confined to the close forest tracts of the northern side,—*Petrocossyphus cinclorhynchus* (Gray's Cat.) affects the rocky southern forest; he had however occasionally seen the latter on the northern side also, but he cannot call to mind a single instance in which he had seen either *Geocichla citrina* or *G. unicolor* on the southern side. This fact will at once show how little applicable to the latter birds is Mr. Gray's name of *Petrocossyphus*. Mr. Gray may possibly reply to this criticism by asking—"what's in a name?" To which Captain Hutton responds that in natural history, as with man, a good name is most important, and ought as much as possible to convey some idea of habits, manners or markings so as to assist the naturalist not only in the identification of species, but also lead him to the places where he might expect to find them. But who would ever dream of seeking in the forests gloom for birds whose name pointed to the fact of their delighting in rocky situations? Yet, if misled by the generic name *Petrocossyphus*, the naturalist should venture to some rock bestudded mountain in search of the species "*citrinus*" and "*unicolor*"—he would have nothing but his trouble as his reward, for those species are procurable only amidst the boughs and thickets of the forest.

No. 26.—"*Copsychus saularis*," (L.)

*Gryllivora intermedia*, Swainson.

*Dahila docilis*, Hodgson.

Arrives on the hills up to 5,000 feet and perhaps higher, in the beginning of April. It returns to the Doon and plains in early autumn. It breeds in May, on the 19th of which month he took a nest from a bank by the road side; it was composed of green mosses and lined with very fine roots, Eggs 4; carneous green colour somewhat blistered at the larger end. Diameter  $\frac{1}{8} \times \frac{9}{16}$  inches.

This species delights to sit on the topmost branches of a tree, generally selecting some dry and leafless branch, from whence it utters a pleasing song, which is replied to by another individual at no great distance, when on the ground it hops with the wings half open or drooping, and at each hop it stops to spread and flit the tail.

No. 27.—"*Stoparola melanops*," (Blyth.)

*Nittava melanops*, (Gray's Cat.)

*Muscicapa melanops*, (Vigors, Gould.)

This is a common species throughout the mountains up to about 12,000 feet during summer arriving about the beginning of March. It breeds in May and June, making a neat nest of green moss in holes of trees, in stumps, and in

the holes of banks by the road side. The eggs are 3 to 4 in number, dull white with faint rufous specks at the larger end and somewhat inclined to form a ring.

The bird has a pleasing song. Gould figures this species very faultily,—as the black of the lores does not pass beyond the eye, as he represents it, and the under tail coverts instead of being uniform pale greenish, are dull blue, greenish, feathers apically barred with dull white. In the winter it leaves Mussooree.

No. 28.—"*Leyornis rubeculoides*," (Blyth.)

*Nittava rubeculoides*, (Hodg.)

*Phænicura rubeculoides*, (Vigors.)

*Chaitaris brevipes*, (Hodg.)

Arrives in the neighbourhood of Mussooree in April, and breeds in June, on the 13th of which month he took a nest from a hole in a bank by the road side in a retired and unfrequented situation. He afterwards found another nest in a hole of a rock, also in a retired spot. The elevation was about 5,000 feet. Externally this nest is composed of green moss and lined with black fibrous lichens like hair. The eggs are 4 in number, of a dull and pale olive green, faintly or indistinctly clouded with dull rufous or clay colour. Diameter  $\frac{1}{8} \times \frac{9}{16}$  inches. The male has a very pleasing song which he warbles forth from the midst of some thick bush, seldom exposing itself to view, like *Stoparola melanops* which delights to perch upon some high exposed twig.

No. 29.—"*Sibia capistrata*," (Hodg.)

Remains at an elevation of 7,000 feet throughout the year, but he never saw it under 6,500 feet. Its loud ringing note of litteree—litteree tweeyo, quickly repeated, may constantly be heard on wooded banks during summer. It breeds at Mussooree in May, making a neat nest of coarse dry grasses as a foundation, covered laterally with green moss and wool, and lined with fine roots. The number of eggs he did not ascertain, as the nest was destroyed when only one had been deposited, but the colour is pale bluish white freckled with rufous. The nest was placed on a branch of a plum tree in the botanical garden at Mussooree.

No. 30.—"*Dierurus longicaudatus*," (A. Hay.)

This species, the only one that visits Mussooree, arrives from the Doon about the middle of March and retires again about September. It is abundant during the summer months, and breeds from the latter end of April till the middle of June, making a very neat nest, which is placed in the bifurcation of a horizontal branch of some tall tree, usually oak trees, it is constructed of grey lichens gathered from the trees, and fine seed-stalks of grasses, firmly and neatly interwoven, with the latter it is also usually lined, although sometimes a black fibrous lichen is used;—externally the materials are kept compactly together, by being plastered over with spiders

## BIRDS OF SOUTHERN ASIA.

webs. It is altogether a light and elegant nest. The shape is circular, somewhat shallow and diameter within 3 inches. The eggs are 3 to 4, —generally the latter number and so variable in colour and distribution of spots, that until he had shot several specimens and compared them narrowly he was inclined to think they had more than one species of *Dicurus* there. He is however now fully convinced that these variable eggs belong to the same species. Sometimes they are dull white with brick red spots openly disposed in form of a rude ring at the larger end; at the other times the spots are rufescent claret with duller indistinct ones appearing through the shell; others are of a deep caraneous hue, clouded and coarsely blotched with deep rufescent claret; while again some are faint caraneous with large irregular blotches of rufous grey with duller ones beneath the shell. Diameter varying from  $1 \times \frac{1}{8}$ ; —to  $\frac{3}{4} \times \frac{1}{8}$  inches.

No. 31.—“*Campephaga fimbriata*.” (Fem.)

*Campephaga lugubris*. (Gray's Cat.)

*Ceblepyris lugubris* (Sundevall.)

*Volvocivora melaschistos* (Hodg. Gray.)

*Graucalus maculösus*, (McClelland.)

This too is a mere summer visitor in the hills, arriving up to 7,000 feet about the end of March, and breeding early in May. The nest is small and shallow, placed as in the last in the bifurcation of a horizontal bough of some tall oak tree, and always high up; it is composed externally almost entirely of grey lichens picked from the tree, and lined with bits of very fine roots or thin stalks of leaves, seen from beneath the tree, the nest appears like a bunch of moss or lichens, and the smallness and frailty would lead one to suppose it incapable of holding two young birds of such size. Externally the nest is compactly held together by being thickly pasted over with cobwebs. The eggs are two in number, of a dull grey green closely and in part confluent dashed with streaks of dusky brown. Diameter  $\frac{3}{4} \times \frac{1}{8}$  inches.

The bird has a plaintive note which it repeatedly utters while searching through a tree, after the manner of *Collurio Hardwickii*, for insects.

No. 32.—“*Abornis schisticeps*.” (Hodg.)

*Culicipeta schisticeps*. (Gray's Cat.)

*Phyllopneuste xanthoschistos*. (Hodg.)

A common species at 5,000 feet and commences building in March. A pair of these birds selected a thick China rose bush, trained against the side of the house, and had completed the nest and laid one egg when a rat destroyed it. He subsequently took two other nests in May, both placed on the ground in holes in the side of a bank by the road side. In form the nest is a ball with a round lateral entrance and is composed externally of dried grasses and green moss, lined with bits of wool, cotton, feathers, thread and hair. In one he recognized more than one lock of his own child's hair, which had been

cut not long before, and had been appropriated by the bird. The eggs are 3 in number and pure white. Diameter  $\frac{1}{2} \times \frac{1}{8}$  inches.

No. 33.—“*Cryptolopha cinereocapilla*.” (Vieillot.)

*Cryptolopha ceylonensis*. (Strick.)

*C. poiocephala* (Swain.)

*Platyrrhynchus ceylonensis*. (Swain.)

He took a nest of this species on the 18th April in a deep and thickly wooded glen at an elevation of about 4,500 feet. It was placed against the moss covered trunk of a large tree, growing by the side of a mountain stream, and was neatly and beautifully constructed of green moss fixed in the shape of a watch pocket at the head of a bed, to the mosses of the tree (with which it was completely blended,) by numerous threads of spiders' webs. The lining was of the finest grass stalks, no thicker than horse-hair, and beneath the body of the nest depended a long bunch of mosses fastened to the tree with spiders' webs, and serving as a support or cushion on which the nest rested securely. Within this beautifully constructed fabric were 4 small eggs of a dull white colour, with a faint olive tinge and minutely spotted with pale greenish brown, and having a broad and well defined ring of the same, near the large end. The eggs were set hard. Diameter  $\frac{1}{2} \times \frac{1}{8}$  inches. Shape bluntly ovate.

No. 34.—“*Parus erythrocephalus*.” (Vig.)

Common at Mussooree and in the hills generally throughout the year. It breeds in April and May. The situation chosen is various, as one taken in the former month at Mussooree, at 7,000 feet, was placed on the side of a bank among overhanging coarse grass, while another taken in the latter month at 5,000 feet, was built amongst some ivy twining round a tree, and at least 14 feet from the ground. It is in shape a round ball with a small lateral entrance, and is composed of green mosses warmly lined with feathers. The eggs are 5 in number, white with pinkish tinge, and sparingly sprinkled with lilac spots or specks, and having a well defined lilac ring, at the large end. Diameter  $\frac{1}{2} \times \frac{1}{8}$  inches.

No. 35.—“*Parus xanthogenys*.” (Vig.)

Common in the hills throughout the year. It breeds in April, in which month a nest containing four partly fledged young ones was found at 5,000 feet; it was constructed of moss, hair and feathers, and placed at the bottom of a deep hole in a stump at the foot of an oak tree; the colour of the egg was not ascertained.

No. 36.—“*Acrocephalus montanus*.” (Gray's Cat.)

*Salicaria arundinacea* (Hodg. Gray.)

This species arrives in the hills up to 7,000 feet at least in April, when it is very common; and appears in pairs with something of the manner of *Phylloscopus*. The note is sharp “*tchik-tchick*,” resembling the sound emitted by a flint

## BIRDS OF SOUTHERN ASIA.

and steel. It disappears by the end of May, in which month they breed, but owing to the high winds and strong weather experienced in that month in 1848, many nests were left incomplete, and the birds must have departed without breeding. One nest which he took on the 6th May, was a round ball with lateral entrance; placed in a thick barberry bush growing at the side of a deep and sheltered ditch; it was composed of coarse dry grasses externally and lined with finer grass. Eggs 3, and pearl white, with minute scattered specks of rufous, chiefly at the large end; diameter  $\frac{1}{8}$  ×  $\frac{1}{8}$  inches. The high winds which prevailed in May, destroyed an incredible number of the nests of various doves, *Treron sphenura*, *Garrulus lanceolatus*, &c.)

No. 37.—“*Zosterops palpebrosus*.” (Temm.)

*Z. annulosus*. (Swain.)

*Motacilla madagascariensis*. (Gm.)

*Sylvia madagascariensis*. (Lin. Lath.)

*Motacilla maderaspatana*. (Lin.)

*Sylvia palpebrosa*. (Tem.)

*S. leucops*. (Vieillot)

*S. annulosa*. (Swain.)

*Zosterops maderaspatana*. (Gray's Cat.)

These beautiful little birds are exceedingly common at about 5,000 feet during summer, but he never saw them much higher. They arrive from the plains about the middle of April, on the 17th of which month he saw a pair commence building in a thick bush of *Hybiscus*? and on the 27th of the same month the nest contained 3 small eggs, hard set. He subsequently took a second from a similar bush, and several from the drooping branches of oak trees, to the twigs of which they were fastened. It is not placed on a branch, but is suspended between two thin twigs, to which it is fastened by floss silk torn from the cocoons of “*Bombyx Huttoni*” (Westwood) and by a few slender fibres of the bark of trees or hair, according to circumstances. So slight and so fragile is the little oval cup, that it is astonishing the mere weight of the parent bird does not bring it to the ground; and yet within it three young ones will often safely outride a gale that will bring the weightier nests of Jays and Thrushes to the ground. Of seven nests then before him, four were composed externally of little bits of green moss, cotton, seed down, and the silk of the wild mulberry moth torn from the cocoons, with which last material moreover, the others appear to be bound together; within, the lining of two is of the long hairs of the Yak's tail (*Bison peophagus*) two of which died on the estate where these nests were found, and the third is lined with black human hair; the other three are formed of somewhat different materials, two being externally composed of fine grass stalks, seed down and shreds of bark, so fine as to resemble tow; one is lined with seed down

and black fibrous lichens resembling hair, another is lined with fine grass, and a third with a thick coating of pure white silky seed down. In all the seven the materials of two sides are wound round the twigs, between which they are suspended like a cradle, and the shape is an ovate cup about the size of half a hen's egg split longitudinally. The diameter and depth are respectively  $2 \times \frac{3}{4}$ ; and  $1\frac{1}{2}$  inches. The eggs usually 3 in number, of a very pale whitish green; diameter  $\frac{5}{16} \times \frac{5}{16}$  inches. The young continue with the old birds for some time. After leaving the nest, and are often mixed up with the flocks of *Parus erythrocephalus*. They appear to feed greedily upon the small blackberries of a species of *Rhamnus* common in these localities. They depart from the Doon about the end of October.

No. 38.—“*Orthotomus longicauda*.” (Gm.)

*O. Bennettii*. (Sykes.)

*O. Suthorius*, *V. ruficapillus*, *V. sphæmura*. (Hodg. Gray.)

• *Motacilla longicauda*. (Gm.)

*M. Sutoria*. (Gm.)

*Sylvia guzuratta*. (Lath.)

*O. lingoo*. (Sykes) Young.

*O. Sepium*. (Sykes) Young apud Blyth.

*O. sphæmurus*. (Swain.)

*Sylvia ruficapilla*. (Hutton.)

It is very evident from the accounts given both by Mr. Hodgson and Captain Tickell, of the colour of the eggs of supposed *O. longicauda*, that there must either be more than one species confounded under that name, or that they have erroneously attributed to it the eggs of some other species. In the J. A. S. No. 22 for October 1833, he described the nest and eggs of the true *O. longicauda*, under the name of *Sylvia ruficapilla*, and similar nests and eggs agreeing in every respect have since fallen under his observation; in all of these the nest was composed of cotton, wool, vegetable fibre and horsehair, formed in the shape of a deep cup or purse enclosed between two long leaves, the edges of which were sewed to the sides of the nest in a manner to support it, by threads spun by the bird, the eggs are 3 to 4, of a white colour, sprinkled with small specks, chiefly at the larger end, of rufous or tawny. Captain Tickell gives the eggs “pale greenish blue, with irregular patches, especially towards the larger end, resembling dried stains of blood, and irregular broken lines scratched round, forming a zone near the large end.” These cannot be the eggs of *O. longicauda*, any more than the “unspotted verditer blue eggs” mentioned by Mr. Hodgson, P. Z. S. 1845. p. 29.

The true *O. longicauda* occurs in the Doon along the southern base of the mountains, but does not ascend even in summer.

No. 39.—“*Drymoica criniger*.” (Hodg.)

• *Suya criniger*. (Hodg.)

This little bird appears on the hills at about

## BIRDS OF SOUTHERN ASIA.

5,000 feet in May. A nest taken much lower down on 22nd June was composed of grasses neatly interwoven in the shape of an ovate ball, the smaller end uppermost and forming the mouth entrance, it was lined first with cottony seed down, and then with fine grass stalks; it was suspended among high grass and contained 5 beautiful little eggs of a caraceous white colour, thickly freckled with deep rufous, and with a darkish confluent ring of the same at the large end. Diameter  $1\frac{1}{8} \times \frac{5}{16}$  inches. I have seen this species as high as 7,000 feet in October. It delights to sit on the summit of tall grass or even of an oak, from whence it pours forth a loud and long continued grating note, like the filing of a saw.

No. 40.—“*Pyrgita indica*” (Jard. Selb.)

This if really distinct from the European Sparrow, does not appear to be a common bird on the heights, nor is it nearly so common at 5,000 feet as it is in the Doon yet it cannot be called scarce. It breeds in the eaves of buildings and in bushes, making a loose slovenly nest of a round form with lateral entrance; it is of large size and constructed chiefly of dry grasses, or hay externally, and plentifully lined with feathers, bits of cotton and wood. The eggs are pale ash colour, moderately sprinkled with specks and dashes of neutral tint, clustering rather thickly at the large end. Diameter  $1\frac{3}{8} \times \frac{9}{16}$  inches. Eggs usually about 6 in number. Breeds several times in the year.

No. 41.—“*Francolinus vulgaris*.” (Steph.)

This is a common bird in the Doon, and by no means rare in warm cultivated valleys far in the hills; it breeds in the hills in June, and a nest taken by a friend on whose accuracy he can rely, and who shot the old bird, contained 6 eggs of a dull greenish white colour, the egg appears very large for the size of the bird, and tapers very suddenly to the smaller end. Diameter  $1\frac{1}{2} \times 1\frac{3}{16}$  ins.

There is no preparation of a nest, the eggs being deposited on the bare ground. Called “Kala teetur” by the natives.

No. 42.—“*Euplocomus albocristatus*.” (Vigors.)

This species, the “Kaliep” of the hill men, is found in the hills at all seasons, and is common at every elevation up to the snows. It breeds in May and June. In the latter month he found a nest, by the side of a small water course, composed merely of a few dead leaves and some dry grasses, which had probably been accumulated by the wind and tempted the bird to deposit her eggs upon them. The spot was concealed by large overhanging ferns, and contained the shells of 8 eggs of a sullied or faint brownish white like some hen’s eggs; the tops of all were neatly cut off as if by a knife, showing that the young ones had escaped, and singular enough he had the day before captured the whole brood, but knowing

the almost impossibility of rearing them had allowed them again to go free. The diameter of the egg is  $2 \times 1\frac{5}{16}$  inches.

• In Mr. Gray’s Catalogue of the Collection presented to the British Museum by Mr. Hodgson, this and *Phasianus Hamiltonii* are given as synonymes of *Gallophasis leucomelanos*. In this there appears to be some degree of error, for the species are distinct. Mr. Blyth in epistola, writes that “there are 4 true races and 2 hybrids. Of the former, one is *albocristatus*; crest rarely very white, the white on the rump always well developed, and found exclusively westward of Nipal. *Melanotus* (Blyth), has black crest, and no white on rump; common at Darjeeling; and the Nepalese *leucomelanos* is certainly a cross between these two. *Cuvieri* of Assam, Sylhet, &c. has white on rump; but underparts wholly shining black; and this has produced a mixed race with *lineatus* of Arracan. If such be the case, the name of *leucomelanos*, belonging only to a true species, must give place to Gould’s name of *albocristatus*. *Phasianus Hamiltonii* of Gray’s III. Ind. Zool. looks very like an immature hybrid. In the neighbourhood of Mussooree and Simla, we have only *Euplocomus* (*Gallophasis*) *albocristatus* (verus) the others all occurring more to the westward as correctly observed by Mr. Blyth. The long white crest is seldom or perhaps never found except in fully mature birds, it being generally of a dirty or dusky hue like that figured in Gould’s Century, every place however is now so thoroughly poached over by native Shikarrees, that an old white crested bird is extremely rare.

No. 43.—“*Pucrasia macrolopha*.” (Gray’s Cat.)

*Phasianus pucrasse*. (Gray Griff, An King.)

*Gallophasis pucrasia*. (Hodg, Gray.)

For the eggs of this species he was also indebted to a friend who took them in June from the ground, where there was no other symptom of a nest than a slight scratching away of the leaves and grass. The eggs were 5 in number, of a sandy brown, sprinkled over with specks, and large spots and blotches of deep red brown resembling dried blood. The diameter was  $2\frac{1}{16} \times 1\frac{7}{16}$  inches. Shape ordinary, and altogether a very close miniature of the egg of *Lophophorus impeyanus*. This bird occurs in the hills at all seasons, from Mussooree to the snows, and bears several names, such as “Plass” at Simla, “Koklass,” at Mussooree, and “Pocrass” farther to the eastward.

No. 44.—“*Phasianus Wallichii*.”

*Lophophorus Wallichii*. (Hardw.)

*Phasianus Stacei*. (Vigors.)

This beautiful species is truly a hill bird being found at all seasons. Its egg is pure white and of the ordinary shape, but the number not ascertained. It is known as the “Cheer,” and “Buncheel.”

## BIRDS OF SOUTHERN ASIA.

No. 45.—“*Lophophorus Impeyanus*.”  
*Phasianus Impeyanus*. (Lath.)  
*L. refulgens*. (Temm.)

These birds do not occur so low down as Mussooree, but are found in abundance on the next range. In days of yore they were found at Simla, but civilization has of late years banished them to the less disturbed localities. It makes no nest, but lays its eggs on the ground, the number not satisfactorily ascertained, as one nest contained 3 and another 4 eggs of a pale brown or sandy hue, thickly sprinkled over with reddish brown spots and dashes.

The diameter  $2\frac{1}{2} \times 1\frac{1}{8}$  inches. Shape ordinary, called “Monaul.”

No. 46.—“*Tragopan Hastingsii*” (Vigors.)

A pair of these birds kept in confinement produced 2 eggs in June, both of which were destroyed by the male; the colour was pale rufous brown like what are usually termed in (India) “game hen’s eggs.” These birds are only found on the loftier hills along the confines of the snow. They lived contentedly in confinement and became exceedingly tame. In the catalogue above referred to, Mr. Gray gives *Satyra melanacephala* of Hardwick’s III Ind. Zool. Plates 46, 47, 48, as synonymous with Gould’s *Tragopan Hastingsii*. This is again erroneous, for the plates quoted, unless intended as caricatures, can never represent *T. Hastingsii* in any state of plumage. Plate 46 gives what is termed “the adult male” and although agreeing pretty well in other respects with *T. Hastingsii*, it is represented with “Ochreous yellow wattles” whereas in living specimens of the latter species, the wattles are of a bright metallic ultramarine blue; those on the head are usually concealed beneath the feathers, and are only occasionally erect when the bird is excited, but never erected as represented in plate 46. Again Plate 47 represents no phase of plumage of *T. Hastingsii*, while Plate 48 purporting to be a female, is in all probability the young male of some other species, but is assuredly not the female of *T. Hastingsii* which is correctly figured by Gould in his *Century of Himalayan Birds*; a comparison of his plate with that of Mr. Gray’s III. Ind. Zool. will, he thinks, be sufficient to convince any one of the total distinctness of the birds represented. He therefore rejects Gray’s Synonymes in toto, and retains *T. Hastingsii* as an undoubtedly good species, peculiar to the snowy regions of the North Western Himalaya; while *Satyra melanacephala*, if it be a species at all, must be sought for farther to the Eastward of the range. At Simla called, “Jahjee;” Mussooree “Jwire;” by Europeans the “Argus Pheasant.”

Mr. Bligh doubts altogether the existence of more than two Himalayan species of this genus, *Hastingsii* in the N. W., and *Cornutus* in the S. W. A third exists is the Chinese *Temminckii*;

and fine specimens of all are in the Society Museum.—*Capt. Hutton, in Ben. As. S. Journ.*

It will have been observed in the above remarks of Captain Hutton, how numerous the birds of India flit from one locality to another, with the changing seasons. The great Migration of Birds to and from Southern India Asia, seems to take place across the mountains of Nepal.

The wading and natatorial birds, generally, make a mere stage of the valley, on their way to and from the vast plains of *India* and *Tibet*, the valley being too small, dry, open, and populous for their taste—especially that of the larger ones. Some, however, stay for a longer or shorter time, in their vernal and autumnal migrations: and some, again, remain throughout that large portion of the year in which the climate is congenial to their habits. Of all of them, the seasons of arrival, both from the north and from the south, are marked with precision; and Mr. Hodgson was led to conclude from what he observed there, that the mass of the gallatores and swimmers are found in the plains of India, only during the cold months: for they all arrive in the valley of *Nepal*, from the north, towards and at the close of the rains; and all as regularly re-appear from the south, upon, or soon after the cessation of the hot weather. In his enumeration of them, therefore, he divides the birds into the three classes, below indicated.

1st.—Of such as usually pass over the valley, seldom alighting, and only for a few hours.

2nd.—Of such as alight and stay for a few days; or, at most, weeks.

3rd.—Of such as seem to seek the valley, not as a caravansary merely, or house of call, for momentary or temporary sojourn in, on their way to some remote abode—but, as their permanent dwelling place for the entire season.

A 4th class will be constituted of such as do not appear to migrate at all; notwithstanding that all their nearest kindred (so to speak) do so regularly.

Class I. embraces,

Order NATATOIRES. Family *Anatidæ*; the Genera *Cygnus* and *Anser*: Family *Colymbidæ*, none; Family *Alcadæ*, none. Family *Pelecanidæ*; the Genera *Phalacrocorax* and *Pelecanus*, Family *Laridæ*; the Genera *Sterna*, *Viralva*, and *Larus*.

Order GRALLATOIRES. Family *Gruidæ*; the Genus *Grus*. Family *Ardeidæ*; the Genera *Ardea*, *Phenicopterus*, *Platalea*, *Ciconia*, *Mycteria*, *Anastomus*, *Tantalus*. Family *Scolopacidæ*, none. Family *Rallidæ*, the Genus *Glareola*. Family *Charadriadæ*, the Genera *Himantopus* and *Oedicnemus*.

Class II. embraces,

Order NATATOIRES. Family *Anatidæ*; the following Genera, *Tadorna*, *Anas*, *Hynchaspis*, *Dafila*, *Mareca*, *Querquedula*, *Merganser*, *Tringula*. Family *Colymbidæ*, none. Family *Alcadæ*

none. Family *Pelecanidae*; the Genera *Phalacrocorax* and *Pelecanus*.

Order GRALLATORES. Family *Gruidae*; the Genus *Anthropoides*. Family *Ardeidae*, the Genus *Ibis*. Family *Scolopacidae*; the Genera *Numenius*, *Limicola*, *Recurvirostra*, *Limosa*, *Rhynchæa*, *Pelinda*, *Phæopus*. Family *Rallidae*; the Genera *Rallus*, *Parra*, *Gallinula*, *Porphyrio*, *Fulica*. Family *Charadriidae*; the Genera *Fregia*, *Squatarola*, *Vanellus*, *Charadrius*.

Class III. embraces,

Order NATATORES. Family *Anatidae*; the Genera *Mareca* and *Querquedula*, (where *protected*, as in some sacred tanks). Family *Colymbidae*, none. Family *Alcedæ*, none. Family *Pelecanidae*, none.

Order GRALLATORES. Family *Gruidae*, none. Family *Ardeidae*, the Genera *Botaurus*, *Ardea*, *Ciconia*. Family *Scolopacidae*, the Genera *Gallinago* and *Scolopax*. Family *Rallidae*; the Genera *Parra*, *Rallus*, and *Fulica* (where *protected* in holy tanks). Family *Charadriidae*; the Genus *Charadrius*, (one small species of.)

Class IV. embraces,

Order NATATORES, none.

Order GRALLATORES. Family *Gruidae*, none. Family *Ardeidae*; the Genera *Ardea*, (small species, or *Baklas*, only) and *Nycticorax*. Family *Scolopacidae*; the Genera *Totanus*? and *Gallinago*? Family *Rallidae*; the Genus *Rallus*. Family *Charadriidae* the Genus *Vanellus*, one species—the *Tithirs*.

N. B.—The notes of interrogation merely denote a doubt whether the Genera so indicated belong to Class III. or IV.

*Remarks upon the above enumeration.*

The Grallatorial and Natatorial birds begin to arrive, from the *North*, towards the close of August, and continue arriving till the middle of September. The first to appear are the common snipe, and jack snipe, and *Rhynchæa*; next, the Scolopaceous waders (except the wood-cock;) next, the great birds of the heron and stork, and crane families; then, the Natatores; and lastly, the woodcocks, which do not reach us till November. The time of the re-appearance of these birds, from the *South* is the beginning of March; and they go on arriving, till the middle of May. The first which thus return to Nepaul are the snipes; then come the teal and ducks; then the large Natatores; and lastly, the great cranes and storks. It will be noticed that the Grallatores which visit Nepaul, or pass over it, are much more numerous than the Natatores; and, he was of opinion that observation in the plains of India would satisfactorily prove that this is a just and decisive indication of the superior prevalence of wading over swimming birds in that extensive region. India, as he supposes is too hot for the taste of the Natatores—a great majority of which seem to affect arctic regions,

or, at least, high latitudes: The wild swan was never seen there but once, in the mid winter of 1828, when the apparition suggested a new version of the well known hexameter.—

‘Rara avis in terris, *alboque* simillima cygno.’

Such a bird is never seen, he supposes in the plains of India?

None of the Natatores stay in Nepaul beyond a week or two, in autumn, (when the rice fields tempt them) or beyond a few days, in spring, *except* the teal, the widgeon, and the coot, which remain for the whole season, upon some few tanks whose sanctity precludes all molestation of them. There are cormorants throughout the season upon the larger rivers within the mountains; but none ever halt in the valley, beyond a day or two: for *so long*, however, both they and pelicans may be seen, occasionally, on the banks just mentioned.

The *Larus* and *Sterna* are birds which usually affect the high seas,—but Mr. Hodgson, had killed both the red-legged Gull, and a genuine pelagic Tern, in the valley of Nepaul. But so had he *fishing* Eagles; and in truth who shall limit the wanderings of these long-winged birds of the *Ethereal* expanse? Mr. Hodgson, in *Asiatic Transactions—Vol. 18 Part ii. for 1838, page 124.*

It will be seen from the above how extended are the wanderings of many of the birds of Southern Asia. This is a subject, indeed, which has been the theme of poets and Naturalists in all ages.

*The Migration of Birds* engaged the pen of Mrs. Hemans, who asks,

Birds, joyous birds of the wandering wing,  
Whence is it ye come with the flowers of spring?

“We come from the shore of the green old Nile,  
From the land where the roses of Sharon smile,  
From the palms that wave through the Indian sky,  
From the myrrh-tree of glowing Araby.

“We have swept o’er the cities, in song renown’d,  
Silent they lie, with the deserts round!  
We have crossed proud rivers, whose tide hath roll’d,  
All dark with the warrior blood of old;  
And each worn wing hath regained its home,  
Under the peasant’s roof-tree, or monarch’s dome.”

And what have ye found in the monarch’s dome,  
Since last ye traversed the blue sea’s foam?

“We have found a change, we have found a pall,  
And a gloom o’ershadowing the banquet’s hall,  
And a mark on the floor, as of life-drops spilt,  
Nought looks the same, save the nest we built!”

## BIRDS OF SOUTHERN ASIA.

Sad is your tale of the beautiful earth,  
Birds that o'ersweep it in power and mirth!  
Yet, through the wastes of the trackless air,  
Ye have a guide, and shall we despair?  
Ye over desert and deep have passed,  
So shall we reach our bright home at last!

*The Migration of Swallows* from the cold regions of the North, has ever been a fertile theme of wonder, and one poet thus alludes to it.

"As fables tell, an Indian sage,  
The Hindostani woods among,  
Could in his desert hermitage,  
As if 't were marked in written page,  
'Translate the wild bird's song.

"I wish I did his power possess,  
That I might learn, fleet bird, from thee,  
What our vain systems only guess,  
And known to what wide wilderness,  
You go across the sea."

The following birds are given in the Calcutta Review (March 1857), as common to England and Southern Asia. We must regard it as from the pen of Mr. Blyth, as there is no naturalist other than him in India equal to the task.

(246) *Gyps Fulvus*. (*Vultur fulvus*; 'Griffon Vulture.') Inhabits the high mountains of Europe and Asia, inclusive of the Himalaya and its vicinity: common in Dalmatia, Greece, and the islands of the Mediterranean; less so on the Alps, and exceedingly rare and accidental in the British islands and northern provinces of France. Replaced in the Pyrenees, Sardinia, and Barbary, by the nearly affined *G. occidentalis*: in E. Africa by *G. Ruppellii*: and in S. Africa by *G. Kolbii*; also generally over India and the Malay countries by *G. indicus*, a much smaller bird. All are remarkable for possessing fourteen tail-feathers, whereas other birds of prey have twelve only; even their congener, *G. bengalensis*, which is the commonest Indian Vulture about and near towns, and is also met with in E. Africa. As Mr. Yarrell does not appear to discriminate the *G. occidentalis*, it is just possible that the bird which he notices appertains to that particular race, rather than to the genuine *G. fulvus* of the Himalaya.

The *G. fulvus* is the 'great white Vulture' of the Himalaya; and the 'great black Vulture' of the Himalaya, *Vultur monachus*, may yet be found to stray so far west as Britain; since it has several times been shot in Schleswig and Holstein, also in Provence, Languedoc, Dauphiné, &c. It is not rare in the Pyrenees, Sardinia, Sicily, and mountainous regions of the S. E. of Europe.

The great African *V. auricularis* has been observed in Greece, and has once been killed in France (in Provence); this resembles *V. ponticerrianus*, the so called 'King vulture' common over the plains of India, but is much larger, equalling *V. monachus* in size; while the latter

has also an analogous diminutive in Africa, in the *V. occipitalis*.

(247) *Neophron Percnopterus*. ('Egyptian Vulture') *Rachamah* of the appendix to Bruce's travels; *Pharaoh's chicken*, &c. Inhabits Europe, Asia, and Africa, abounding in most warm regions; very common on the plains of Upper Hindustan, and the table-land of peninsular India; but not observed in Lower Bengal below the tideway of the Gangetic rivers: common in the southern parts of Europe; but very rare and accidental in the British islands, and also in Scandinavia. This bird is evidently the 'Kite' of Major A. Cunningham's 'Ladak' (p. 205). He writes—"the eagle (*cha-nak*, or the 'black bird') and the kite (*chakor*, or the white bird) are common enough, and so is the large raven." A second species of this genus, the *N. pileatus*, inhabits Africa only.

(248) *Gypaetos*. The Lämmergeyer (*Gypaetos*) inhabits the high mountains of Europe, Asia and Africa; from the Altai even to the Cape colony. Authorities differ with respect to the value to be attached to certain differences observed in specimens from different regions. The prince of Camino identifies the Himalayan with *G. barbatus* of Gebler from the Altai, and *G. nudipes* of Brehm (*meridionalis* of Keyser and Blasius) from S. Africa. M. Malherbe remarks that specimens from the Pyrenees and Sardinia are of inferior size to those from the Swiss Alps; and this smaller race is the *G. barbatus occidentalis* of Schlegel. Even the Himalayan is said to differ from that of eastern Europe by having a pictorial dark band not observed in the other, and is the *G. hemachalanus* of Captain Hutton. The constancy of the alleged distinctions seems to need confirmation, preparatory to an estimation of their value. The Himalayan bird is commonly mis-called 'Golden Eagle' by English residents.

(249) *Aquila Chrysaetos* ('Golden Eagle') Inhabits the mountainous regions of Europe, Asia, and N. America (being the only true *Aquila* in the New World); rare in N. Africa; and in India confined to the Himalaya. M. Degland inclines to the opinion that a larger and smaller race exist, the former inhabiting a colder region; but this much needs confirmation. We can perceive no difference between British and Himalayan examples.

(250) *Aquila mogilnik* or 'Imperial Eagle' of Temminck (*Aq. heliaca*, Savigny) inhabits generally a warmer climate than *Aq. Chrysaetos*, and is extensively diffused over the mountainous regions of S. E. Europe, Asia, and N. Africa, including those of India (being the *chrysaetos* of Dr. Jerdon's Catalogue of the birds of S. India). In Europe it has been observed so far north as in Jutland; but never in the British islands,

## BIRDS OF SOUTHERN ASIA.

(246) *Aquila naevia*. ('Spotted Eagle.') Inhabits Europe, Asia, and Africa; being common in the hilly parts of India, and even in the Bengal Sundarbans. Very rare in N. Europe: but has been shot near the town of Schleswig, and has even been known to breed in Ireland.

There are two affined species in India, *Aq. hastata*, nearly as large but less robust, and *Aq. fulvescens*, distinct from *Aq. naevioides* of Africa (the 'Wokhab' noticed in *Cyc. of India*), which is smaller and more robust, - a miniature of *Aq. mogilnik*. Neither of them has been observed in Europe.

(247) *Eutolmaetos fasciatus*. (*Falco Bonellii*, de la Marmor.) Inhabits the southern parts of Europe, with Asia, and N. Africa; being replaced in S. Africa by *Eu. bellicosus*: in India and Ceylon confined to the hilly parts, where far from rare.

(248) *Hieraetus pennatus*. Inhabits E. Europe, Asia, Africa, India generally, and Ceylon: differing very little (if at all) from *H. morphnoides* of Australia: a rare species in Europe. Prof. Schlegel doubts the proper *habitat* of this bird: it is not uncommon in India, preying much on domestic Pigeons.

(249) *Pandion haliaetus*. ('Osprey.') Of universal distribution; the Australian only differing but slightly. Common in India; and migratory in the far north.

(250) *Falco candicans*. (*Falco gyrfalco*; 'Gyr Falcon.') An Arctic species, very rare in temperate regions: the *Shangar* of Indian falconry seems to denote it, as a bird of excessively rare occurrence in the Punjab. Some writers separate from it an Icelandic race, either as a distinct species or variety, respecting which there is much difference of opinion.

(251) *Falco sacer*. Schlegel (*F. lanarius* apud Temminck and Gould), a very rare species in East Europe, seems to belong properly to Middle Asia, and occurs rarely in the Himalaya.

(252) *Falco lanarius*. Schlegel, an inhabitant of the South East of Europe, differs very slightly from the Indian *F. juggur*, Gray.

(253) *Falco peregrinus*. ('Peregrine Falcon.') Inhabits Europe, Asia, North Africa, if not also North and South America: the South African race smaller; and Australian *F. macropus* (*melanogenys* of Gould) very nearly affined. Common in India; also a nearly affined species, *F. peregrinator*, which resorts more to the hills, and is the *F. ruber indicus* of Aldrovand. Although the Indian and also the north American races are considered different from the European by some, we doubt the existence of any permanent distinction whatsoever.

(254) *Hypotriorchis subbuteo*. (*Falco subbuteo*; the 'Hobby.') All Europe, Asia and Africa; migratory: common in the Himalaya; rarer in S. India; a cold weather visitant in Lower Bengal, together with an affined species,

*H. severus*. Both are somewhat crepuscular in habit.

(255) *Erythropus vespertinus*. (*Falco rufipes*; the 'Red-footed Falcon.') Europe, Asia, and N. Africa: rare in Britain: not uncommon in India, in large flocks, which visit Lower Bengal during the rainy season.

(256) *Erythropus Cenchris*. (*Falco tinnunculoides* of Vieillot.) Resembles *E. vespertinus* in structure and habits and both appear to be exclusively insectivorous, seizing their prey on the ground and not habitually on the wing (like the 'Hobby'). Geographical range also similar, or nearly so; but this has not been known to stray into Britain. Both are migratory.

(257) *Tinnunculus alaudarius*. *Falco* (*tinnunculus*; the 'Kestrel.') All Europe, Asia, Africa, with the great Asiatic archipelago. Very common in India, sometimes in large flocks. The commonest bird of prey in England and France.

(258) *Astur palumbarius*. ('Goshawk') Europe, Asia, and N. Africa: rare in Britain; much commoner in Scandinavia, and generally over Europe, where migratory: common in the Himalaya.

(259) *Accipiter nisus*. ('Sparrow-hawk.') Europe, Asia, and N. Africa: common in the hilly parts of India; rare in the plains, where abundantly replaced by *micronisus badius*. Migrates partially in northern regions. There is a nearly affined race in the Malay countries, *Acc. nisoides*, distinguished by having a white throat with three distinct dark stripes, and no rufous on the under-parts of the adult male. In other respects, quite similar to *Acc. nisus*; and by no means to be confounded with *Acc. virgatus*, which likewise has the throat-stripes.

(260) *Buteo vulgaris*. ('Common Buzzard.') Europe, N. Africa, Asia Minor: higher mountains of India; being common in the W. Himalaya, rare in the Nilgiris, and replaced on the plains by *B. canescens*. Rare, and to the northward and far west only, in America: mostly migratory in Scandinavia.

(261) *Pernis apivora*. ('Honey Buzzard') Europe, Asia, N. Africa: migratory. In India common (if identically the same), in addition to *P. cristata*. In the crestless or sub-crested Indian specimens (adults), there is a marked tendency to the development of three dark stripes on a white throat, and in the *Astur trivirgatus* and sundry other Indian species. Can such be of a hybrid race between *P. apivora* and *P. cristata*?

(262) *Circus aeruginosus*. ('Marsh Harrier.') Europe, Asia, N. Africa: very common in India. Migrates in Scandinavia.

(263) *Circus cyaneus*. ('Hen Harrier.') Europe, Asia, Africa: the American *C. Uliginosus* barely if at all, separable. In India common in the Sub Himalaya region and

## BIRDS OF SOUTHERN ASIA.

its vicinity: being replaced southward by *C. Swainsonii* (*Pallidus* of Sykes.)

(264) *Circus cineraceus*. (*C. Montagu*; *Montagu's Harrier*.) Europe, S. Asia, Africa: very common in India.

(265) *Circæetus gallicus* is a bird of South Europe, Asia, and Africa, which is common in India, and has been killed in Denmark; but never in the British Islands.

(266) *Bubo maximus*. ('Eagle Owl.') Europe, Siberia, China, Asia Minor, Babylonia, Barbary; Himalaya? If so, very rare.

(267) *Scops aldrovandi*. ('Scops eared Owl.') Europe, Asia Minor, N. Africa: migratory. In India replaced by affined species; more especially *Sc. bekkamœna* (*the Scops sunia et pennata* of Hodgson) which seems to be generally diffused over the country. *Sc. Aldrovandi* is admitted in the Catalogue of species from Nepal and Tibet presented to the British Museum by Mr. Hodgson; but referring doubtless to a grey specimen of the *bakkamœna*. Gradations from the grey to the chesnut-coloured varieties of *Sc. bakkamœna* may be seen in the museum of the Asiatic Society, Calcutta.

(268) *Asio otus*. (*Otus vulgaris*; 'Long-eared Owl.') Europe, N. Africa, Asia Minor, N. Asia, N. America: in India, confined to the Himalaya, where not uncommon.

(269) *Asio brachyotus*. (*Otus brachyotus*; 'Short-eared Owl') Europe, Asia, Africa N. and S. America: migratory. Common in India.

(270) *Syrnium aluco*. (*S. stridulum*; 'Tawny Owl') Europe, N. Africa, Asia Minor, N. Asia to Japan (Temminck). *S. nivicolus*, common in the W. Himalaya, rarer eastward, is barely separable.

(271) *Athene psilodactyla*. (*Noctua passerina*; 'Little Owl.') Europe, N. Africa, W. Asia, Afghanistan, N. W. Himalaya. A much larger species than the true *Ath. passerina* (*Strix acadica* of Temminck) of N. Europe, which has not been observed in the British Islands.

(272) *Turdus viscivorus*. ('Missel Thrush.') Europe, W. Asia: its representative in the W. Himalaya appears to be constantly a little larger and has more of the whitish hue upon the outermost tail-feathers; upon which slight differences, M. Homeyer distinguishes it by the name *T. Hodgsoni*.

(273) *Oreocincla Whitei*. (*Turdus Whitei*; 'White's Thrush.') A Siberian species, according to the Prince of Canino, with 14 tail-feathers! Distinct from the very similar *O. dama* of India (from the Hindustani word *Dama*, equivalent to 'Thrush'), with which it has been supposed identical.

(274) *Turdus pilaris*. ('Fieldfare.') Europe, W. Asia: migratory. One specimen has been killed at Saharunpur. In the Himalaya generally, replaced by *T. atrogularis*, a com-

mon bird of N. Asia, which occasionally strays into Europe and has been obtained so far west as in Denmark; in this country it occurs sparingly in Lower Bengal during the cold season. *T. fascatus* of Pallas (*Naumanni* of Temminck), another species inhabiting Siberia and Japan, and straying rarely into Europe, has been once obtained in Nepal.

(275) *Turdus iliacus*. ('Redwing') Europe, W. Asia, Barbary; has been observed in large flocks in Kohat. Migratory: breeding in the extreme north.

(276) *Turdus merula*. ('Blackbird.') Europe, W. Asia, N. Africa, Maderia; Afghanistan? Kashmir? China? We have seen females from Afghanistan and Chusan, which we could not distinguish from the common European Blackbird; and are assured of its being common in the mountains surrounding Kashmir, at from 10,000 to 13,000 feet elevation. The Prince of Canino has recently distinguished a nearly affined "*Merula dactyloptera*" from Syria.

(277) *Turdus or Merula similima*. Of the mountainous parts of S. India and M. Kinnisii of those of Ceylon, though nearly affined, are sufficiently well distinguished from the Blackbird of Europe. In the Himalaya generally, the latter is replaced by *M. bouboul* (*pæcilopectera* of Vigors), which is not unfrequently brought in cages to Calcutta, where known as the 'Kastura.'

(278) *Cyanecula wolff*. (*Phænicura suecica*; 'Blue-throated Warbler.') Europe, W. Asia, Japan (Temminck), N. Africa; rare in Britain: migratory: abundantly replaced in India by *C. suecica*, and in middle Asia, Afghanistan, &c., by *S. cærulecula* (*cyane* of Eversmann); the first known by its pure white pectoral spot, which spot is always deep ferruginous in the Indian bird, and is wanting in that from middle Asia.

(279) *Ruticilla phænicurus*. (*Phænicura ruticilla*; 'Redstart.') Europe, W. Asia, Siberia (Schlegel), Japan, (Temminck,) N. Africa: migratory. Replaced in Sindh and Afghanistan by *R. phænicuroides*, which is probably the *phænicurus* noted from Nepal. There are numerous Himalayan species; and one, *R. rufiventris*, is generally diffused over India.

(280) *Pratincola rubicola*. (*Saxicola rubicola*; 'Stone-chat.') Europe, N. Africa, Japan (Temminck.) In India replaced by the nearly affined *Pr. indica*, and in Sindh also by *Pr. leucura*, as in S. Africa by *Pr. pastor*.

(281) *Pratincola rubetra*. (*Saxicola rubetra*; 'Whinchat.') Europe, N. Africa, Arabia (Schlegel): migratory. Erroneously assigned to India.

(282) *Saxicola ænanthe*. ('Wheatear.') Europe, W. Asia, plains of Upper India, N. Africa, Arctic regions, Greenland! Migratory.

There are several other Indian Wheatears, all of which are different from those of Europe excepting *S. leucomela*; but *S. stapaizina* is re-

placed in India by *S. atrogularis*, and *S. leucura* by *S. leucuroides* (*opistholeuca* of Strickland) which occurs likewise in N. E. Africa.

(283) *Locustella rayi*. (*Salicaria locustella*; 'Grasshopper Warbler.') Europe, Asia, N. Africa: migratory. Has once been obtained in Central India, and once in Lower Bengal; where an affined species, *L. Rubescens*, is not uncommon. Both specimens are in the Calcutta museum.

(284) *Acrocephalus arundinaceus*. (*Salicaria turdoides*; 'Thrushlike Warbler.') Europe, N. Africa, Arabia (Schlegel), Japan (Temminck); rare in Britain: migratory. Replaced in India by *Acr. brunescens*.

(285) *Sylvia atricapilla*. (*Currucula atricapilla*; 'Blackcap Warbler.') Europe, W. Asia, Arabia (Schlegel), Japan (Temminck), all Africa. One killed in Java (Temminck.)

(286) *Sylvia cinerea*. (*Currucula cinerea*; 'Common White-throat.') Europe, Asia Minor, Arabia (Schlegel), N. Africa: migratory.

(287) *Sylvia curruca*. (*Currucula sylvicola*; 'Lesser White-throat.') Europe, Asia, Africa: migratory. Common in India; and a nearly affined but larger species in S. India, *S. affinis* (*Currucula cinerea* apud Jerdon)

(288) *Sylvia orphea*. (*Currucula orphea*; 'Orpheus Warbler.') Europe, N. Africa, Arabia, (Schlegel) rare in Britain: migratory. The Indian race seems to differ only in having a somewhat longer bill: inhabiting both Upper Hindustan and S. India.

(289) *Phylloscopus trochilus*. (*Sylvia trochilus*; 'Willow Warbler.') Europe, Asia Minor, N. Africa; W. India (apud Gould, but needs confirmation): migratory. Has been known to stray to N. America.

(290) *Regulus cristatus*. ('Golden-crested Regulus.') Europe, N. Asia, Japan, W. Asia, Barbary: partially migratory. Replaced in the W. Himalaya by *R. himalayensis*.

(291) *Reguloides proregulus*. (*Regulus modestus*; 'Dalmatian Regulus.') Asia; very rare in Europe: one specimen obtained in Dalmatia and another in England. Common in India with several affined species.

(292) *Parus major*. ('Great Tit.') Europe, N. Asia, Japan, N. Africa. Replaced in India, Ceylon, and Java, by *P. cinereus*, and in the Himalaya also by *P. monticolus*.

(293) *Parus cæruleus*. ('Blue Tit.') Europe, N. Asia, Japan, China Formosa.

(294) *Parus ater*. ('Cole Tit.') Europe, Siberia, Japan, Formosa. Replaced in Nepal by *P. cæmodius*.

(295) *Orites caudatus*. (*Parus caudatus*; 'Long-tailed Tit.') Europe, N. Asia, Japan.

(296) *Calobates sulphurea*. (*Motacilla boarula*; 'Grey Wagtail.') Europe, Asia, Africa, Malay countries, Australia? Migratory within the British islands: common in India.

(297) *Pipastes trivialis*. (*Anthus arboreus*; 'Tree Pipit.') Europe, N. Asia, Japan, W. Asia, N. Africa; Himalaya (but much confounded with the common *P. agilis* of India): migratory.

(298) *Anthus pratensis*. ('Meadow Pipit.') Europe, N. Asia, Japan, Asia Minor, W. India, (Gould), Nepal (Hodgson, Gray); one specimen received from Pegu.

(299) *Anthus obscurus*. (*A. petrosus*; 'Rock Pipit.') Europe, Siberia, Japan. Replaced in the Himalayan region by *A. Cervinus*, which is likewise found in Europe.

(300) *Corydalla Richardi*. (*Anthus Ricardi*; 'Richard's Pipit.') Europe, Asia, N. Africa; common in India; very rare in Britain.

(301) *Corydalla campestris*. A common European bird which even abounds in the southern parts of Sweden, but has not hitherto been observed in Britain, is also common in parts of India.

(302) *Galerida cristata*. (*Alauda cristata*; 'Crested Lark') Europe, Asia, N. Africa; rare in Britain; common in India, where known as the *Chandul*.

(303) *Calendrella brachydactyla*. (*Alauda brachydactyla*; 'Short-toed Lark.') S. Europe, N. Africa; rare in Britain; extremely common in India, where currently known to Europeans as the 'Ortolan.'

(304) *Certhilanda desertorum* of Spain and N. Africa inhabits Sindh; and the *Ammomanes Lusitonia* occurs in the deserts of N. W. India, being replaced further south by *A. phœnicura*.

(305) *Emberiza miliaria*. ('Common Bunting.') Europe, W. Asia, Arabia (Schlegel), Barbary.

(306) *Emberiza citrinella*. ('Yellow Bunting.') Europe, to beyond the polar circle: replaced in the W. Himalaya by *E. pithyornis*, an inhabitant also of Siberia, which occurs rarely in W. Europe.

(307) *Emberiza Cía* of S. Europe is common in the W. Himalaya; and *E. Pusilla*, which seems to be plentiful in Sikhim, has occasionally been observed in Europe, even so far west as Leyden. *E. fucata* of N. Asia, Japan, and common in the W. Himalaya, occurs sometimes in considerable numbers in Lower Bengal. *E. melanoccephala* of S. Europe is common in parts of India.

(308) *Fringilla montifringilla*. ('Mountain Finch.') Europe, N. Asia, Japan, Asia Minor, Afghanistan, Kashmir, W. Himalaya; a winter visitant in Britain. The European *Montifringilla Nivalis* has been obtained at Kandahar.

(309) *Passer montanus*. ('Tree Sparrow.') Europe, Asia (commoner to the eastward) Siberia, Tibet, Sikhim, Arakan, Malayan peninsula, Java, China, Japan.

(310) *Passer domesticus*. ('House Sparrow.') Europe, Asia, N. Africa; the Indian race (*P. indicus* of Jardine and Selby) differing slightly

from the European in the paleness of the females and young, the much more albescent hue of the lower-parts, and bright rufous colouring on the back of the adult male.

(311) *Passer salicarius*. (*vel hispaniolensis*) of Barbary and the southern parts of Europe, Asia Minor, Bokhara, and Afghanistan, visits the Peshawur valley and Kohat in large flocks, being everywhere more highly gregarious than *P. domesticus*. *P. Petronia* (*V. Petronia Stulta*), also of S. Europe and N. Africa to Madeira; is common in Afghanistan.

(312) *Coccothraustes vulgaris*. ('Hawfinch.') Europe, Siberia, China, Japan (*qu. C. Japonicus*, Schlegel?)

(313) *Chrysomitris spinus*. (*Carduelis spinus*; 'Siskin.') Europe, Siberia, Japan: a winter visitant chiefly in Britain, breeding in the far north.

(314) *Linota cannabina*. ('Common Linnet.') Europe, Siberia, Japan, Asia Minor, Barbary.

(315) *Linota canescens*. ('Mealy Redpole.') Northern regions chiefly, Greenland, Japan: an irregular winter visitant in Britain.

(316) *Linota montium*. ('Mountain Linnet.') Europe, N. Asia, Japan: N. or S. Britain according to season: replaced in Afghanistan by *L. Brevirostris*.

(317) *Carpodacus erythrinus*, which is rare in the N. E. of Europe, is a common winter visitant over the greater part of India.

(318) *Loxia curvirostra*. ('Common Crossbill.') Circuit of northern regions: all Europe; Afghanistan: an irregular visitant in Britain: in America it has been obtained so far south as in the Bermudas. A much smaller species inhabits the Himalaya, the *L. Himalayana*.

(319) *Loxia bifasciata*. ('European White-winged Crossbill.') N. Europe and Asia. Himalaya (Gould): rare in Britain.

(320) *Sturnus vulgaris*. ('Common Starling.') Europe, Asia, Africa, Azores: common in the Himalaya and N. India, Kashmir, Afghanistan, &c., as in Britain. N. B.—An Afghan specimen, assigned to *St. Unicolor*, appertains to the present species, being an old male with the pale specks obsolete: the true *St. Unicolor* of Sardinia, Barbary, &c., is very distinct and much less bright in its glosses.

(321) *Pastor roseus*. ('Rose-coloured Pastor.') Europe, Asia, and Africa: common in India; rare in Britain.

(322) *Fregilus graculus*. ('Chough.') High mountains and sea-cliffs of Europe, Asia, and Africa: common in high Central Asia, the Himalayas, Afghanistan, &c.; as is also the *Pyrrhocorax alpinus* of the Swiss Alps and Pyrenees.

(323) *Corvus corax*. ('Raven.') Circuit of northern regions; rare in N. Africa, Punjab, Kashmir, Afghanistan; the Tibetan species con-

sidered distinct, but probably on insufficient evidence.

(324) *Corvus corone*. ('Carion Crow.') Europe, Afghanistan, (Pushut), Japan (*apud Temminck*).—Replaced in India by *C. Culminatus*.

(325) *Corvus cornix*. ('Hooded Crow.') Europe, Asia Minor, Afghanistan, Japan (Temminck), Barbary. Considered by some to be identical in species with No. 131.

(326) *Corvus frugilegus*. ('Rook.') Europe, N. and W. Asia, Afghanistan, Peshawur valley, Kashmir: replaced in China and Japan by *C. Pasinator*.

(327) *Corvus monedula*. ('Jackdaw.') Europe, Siberia, Barbary, W. Asia, Peshawur valley, Kashmir.

(328) *Pica caudata*. ('Magpie.') Europe, W. Asia, Siberia, E. N. America, China? Japan? Replaced in Afghanistan and W. Tibet by *P. bactriana*, in E. Tibet by *P. bottanensis*, in China and Japan (?) by *P. media* and Barbary by *P. mauritanica*.

(329) *Funx torquilla*. ('Wryneck') Europe, Asia, N. Africa, China, Japan, Kamischatka; common in India, as in Britain: migratory.

(330) *Upupa epops*. ('Hoopoe.') Europe, Asia, Africa; a common winter-visitant in Lower Bengal, but generally replaced by a nearly allied race in Upper Hindustan and S. India.

(331) *Sitta syriaca*, or 'Rock Nuthatch' of S. E. Europe, and Asia Minor, or a species of similar habits (most probably the same), inhabits Afghanistan:

(332) *Tichodromus muraria*, or Wall Creeper of S. Europe, is very common in the Himalaya, Afghanistan, &c.

(333) *Cuculus canorus*. ('Common Cuckoo.') Europe, Asia, Africa, Malay countries: common in the Himalaya, visiting the plains during the cold season.

(334) *Coracias garrula*. ('Roller.') Europe, Africa, W. Asia, Afghanistan, Kashmir, Sindh, Punjab? migratory in Europe; and rare in Britain.

(335) *Merops apiaster*. ('Bee-eater.') Europe, Africa, W. Asia, Afghanistan, Kashmir, Sindh, Punjab? migratory in Europe, and rare in Britain.

(336) *Hirundo rustica*. ('Swallow.') Europe, Asia, Africa; migratory: common in the plains of India during the cold season.

(337) *Hirundo urbica*. ('Martin.') Europe, Africa, Asia, (Siberia;) somewhat rare (or local?) in India: migratory.

(338) *Hirundo riparia*. ('Sand Martin.') Europe, Asia, Africa, N. America; migratory: in India local, and mostly replaced by *H. sinensis*.

(339) *Hirundo rupestris* of S. Europe is common in the high mountains of India; and there is a diminutive of it also in the *H. concolor* of Sykes.

(340) *Cypselus Apus*. ('Common Swift.')

# BIRDS OF SOUTHERN ASIA.

Europe, N. Africa, W. Asia, Afghanistan; migratory.

(341) *Cypselus melba* (*C. alpinus*; 'Alpine Swift.') High mountains (chiefly) of Europe, Asia, and Africa: tolerably common in the Himalaya, Central India, Nilgiris, and Ceylon: rare in Britain.

(342) *Acanthylis caudacuta*, or large Spiny-tailed Swift of the Himalaya, has once been shot in England, according to Mr. Gould.

(343) *Caprimulgus Europæus*. ('Night-jar,') Europe, N. Africa, W. Asia; Siberia and Kamtschatka (Pennant:) migratory. Several species inhabit India.

(344) *Columba livia*. ('Rock Dove.') Europe, N. Asia to Japan, N. Africa: abundantly replaced in India by the barely separable *C. intermedia*.

(345) *Sterna cinerea* (*Perdix cinerea*; 'Common Partridge.') Europe, S. Siberia, Asia Minor: Mesopotamia? Persia? Egypt? a near congener lately discovered in Tibet.

(346) *Coturnix vulgaris*. ('Common Quail.') Europe, Asia, Africa: chiefly migratory. Abundant in India, though M. Gould considers the race of this country to be distinct.

(347) *Tetrao campestris*. (*Otis tetrao*; 'little Bustard.') Europe, N. Africa, Asia Minor, Mesopotamia, extreme N. W. of India (Peshawar valley.)

(348) *Houbara Macqueenii*. (*Otis Macqueenii*; 'Maqueen's Bustard.') N. W. of India, Afghanistan, &c. Very rare in Europe.

(349) *Edicnemus crepitans*. ('Great Plover.') Europe, Asia, Africa: common in India.

(350) *Charadrius hiaticula*. ('Ringed Plover,') Europe, N. Asia, Japan, Greenland.

(351) *Charadrius cantianus*. ('Kentish Plover.') Europe, Asia: not uncommon in India.

(352) *Charadrius philippinus* (*Ch. minor*; 'Little Ringed Plover.') Europe, Asia, N. America: rare in Britain; exceedingly common in India. *Charadrius pyrrhothorax*, a very common Indian species, is known in Europe as a straggler.

(353) *Calidris arenaria* ('Sanderling.') Circuit of northern regions, N. and S. Africa, N. Guinea: rare in India (so far as observed hitherto; but probably not so along the sea-coast.

(354) *Squatarola helvetica* (*Sq. cinerea*; 'Grey Plover.') Circuit of northern regions, Japan, Java, N. Guinea, Australia: tolerably common in India.

(355) *Vanellus cristatus*. ('Lapwing.') Europe N. and middle Asia, N. Africa: common in N. India, Sindh, &c., but not seen in Lower Bengal.

(356) *Streptopus interpres* ('Turnstone.') Inhabits all sea-coasts, from the equator to the poles: common along those of India.

(357) *Hæmatopus ostralegus*. ('Oystercatcher.') Circuit of northern regions, to the equator, if not further south: not rare along the shores of the Bay of Bengal, &c.

(358) *Grus cinerea* ('Common Crane.') Europe, Asia, N. Africa: migratory; now rare in Britain: common in India during the cold season.

(359) *Ardea cinerea*. ('Common Heron.') Europe, Asia, N. and S. Africa: common in India.

(360) *Ardea purpurea*. ('Common Heron.') Europe, Asia, Africa: common in India.

(361) *Herodias alba*: *Ardea alba*; 'Great White Heron,') Europe, Asia, N. Africa: very rare in Britain: very common in India, though the race is considered different by some.

(362) *Herodias garzetta* (*Ardea garzetta*; 'Little Egret.') Europe, Asia, N. Africa: exceedingly rare in Britain: very common in India.

(363) *Herodias bubulcus* (*Ardea russata*; 'Buff-backed Heron.') Europe, Asia, N. Africa. exceedingly rare in Britain: very common in India.

(364) *Ardetta minuta*. (*Botaurus minutus*; 'Little Bittern.') Europe, all Africa, W. Asia, Himalaya, Kashmir; replaced in Lower Bengal by *A. sinensis*, and more abundantly by *A. cinamomea*, which is common throughout India.

(365) *Botaurus stellaris*. ('Common Bittern.') Europe, Asia, all Africa: common in India.

(366) *Nycticorax Gardeni*. ('Night Heron.') Europe, Asia; Africa, N. America (? Species at least barely separable): very common in India.

(367) *Ciconia alba*. ('White Stork.') Europe, Asia, N. Africa, migratory: common in India during the cold season in immense flocks in Lower Bengal.

(368) *Ciconia nigra*. ('Black Stork.') Europe, Asia, N. Africa: not uncommon in India.

(369) *Platalea leucorodia*. ('White Spoon-bill.') Europe, Asia, all Africa: common in India.

(370) *Fulcinellus igneus*. ('Ibis fulcinellus; 'Glossy Ibis.') Europe, Asia, Africa, N. and S. America, Australia: very common in India.

(371) *Numenius arquata*. ('Common Curlew.') Europe, N. Africa, Asia (to Japan), Malasia: very common in India.

(372) *Numenius phæopus*. ('Whimbrel.') Europe, Asia, N. Africa: common in India, along sea-coast and estuaries.

(373) *Totanus fuscus*. ('Spotted Red-shank.') Europe, Asia: common in India.

(374) *Totanus calidris*. ('Common Red-shank.') Europe, Asia: very common in India.

(375) *Actitis ochropus*, (*Totanus ochropus*; 'Green Sandpiper.') Europe, Asia, N. Africa: very common in India.

(376) *Actitis glareola*. (*Totanus glareola*; 'Wood Sandpiper.') Europe, Asia, Africa, from Lapland to the Cape of G. Hope: Java, &c.: exceedingly common in India.

(377) *Actitis hypoleucos*. (*Totanus hypoleucos*; 'Common Sandpiper.') Europe, Asia: exceedingly common in India.

(378) *Totanus glottis*. ('Green-shank.') Europe, Asia: common in India.

## BIRDS OF SOUTHERN ASIA.

Europe, Asia, Africa, Australia; stragglers obtained in N. America: very common in India.

(379) *Recurvirostra avocetta*. ('Avocet.') Europe, Asia, all Africa: not rare in India.

(380) *Himantopus candidus*. (*H. melanopterus*; 'Black-winged Stilt.') Europe, Asia, all Africa: common in India.

(381) *Limosa algocephala*. (*L. melanura*; 'Black-tailed Godwit.') Europe, Asia, N. Africa, Australia: very common in India.

(382) *Limosa rufa*. ('Bar-tailed Godwit.') Europe, N. Africa, W. Asia: Nepal (Hodgson, Grey), Java and Timor (Temminck).

(383) *Philomachus pugnax*. (*Machetes pugnax*; 'Ruff.') Europe, Asia, N. Africa: common in India.

(384) *Scolopax rusticola*. ('Woodcock.') Europe, Asia, N. Africa: very common in Himalaya, not rare in the Nilgiris, more so in the highlands of Ceylon; a specimen occasionally shot in Lower Bengal.

(385) *Gallinago scolopaciinus*. (*Scolopax gallinago*; 'Common Snipe.') Europe, Asia, N. Africa: very common in India.

(386) *Gallinago gallinula*; (*Scolopax gallinula*; 'Jack Snipe.') Europe, Asia, Barbary: common in India.

(387) *Tringa subarquata*. ('Curlew Sandpiper.') Circuit of northern regions, to beyond the equator; Australia; Very common in India.

(388) *Tringa canutus*. ('Knot.') Circuit of northern regions: rare in India.

(389) *Tringa platyrhynchos*. ('Broad-billed Sandpiper.') Europe, Asia; Sumatra, Borneo, Timor (Temminck); not uncommon in India: rare in the U. S. of America.

(390) *Tringa minuta*. ('Little Stint.') Europe, Asia: very common in India.

(391) *Tringa Temminckii*. ('Temminck's Stint.') Europe, Asia, N. Africa: common in India.

(392) *Tringa alpina*. (*Tringa variabilis*; 'Dunlin.') Arctic regions; circuit of northern regions; Japan; Timor (Temminck); Guiana: not rare in India.

(393) *Phalaropus fulicarius*. ('Grey Phalarope.') Circuit of northern regions: one specimen obtained near Calcutta.

(394) *Lobipes hyperboreus*. (*Phalaropus hyperboreus*; Red-necked Phalarope.) Circuit of northern regions: one specimen obtained near Madras, another in Nicaragua, and a pair in the Bermudas.

(395) *Crex pratensis*. ('Landrail.') Europe, Asia, N. Africa: common in Afghanistan, rare in the N. W. of India: specimen obtained in the Bermudas.

(396) *Porzana Marnetta* *Crex porzana*; 'Spotted Crake.') Europe, Asia, N. Africa: common in India.

(397) *Porzana pusilla* (*Crex pusilla*; 'Little

Crake.') Europe, N. Africa, W. Asia, Japan: Nepal (Hodgson.)

(398) *Porzana Baillonii* (*Crex Baillonii*; 'Baillon's Crake.') Europe, Asia to Japan, all Africa: exceedingly common in India.

(399) *Gallinula chloropus*. ('Moorhen.') Europe, Asia, all Africa: common in India.

(400) *Fulica atra* ('Common Coot.') Europe, Asia, N. Africa, where found additional to *F. cristata*: America and Javanese species distinct: common in India.

(401) *Anser cinereus* (*Anser fesus*; 'Grey-leg Goose.') Europe, and Asia: common in India.

(402) *Anser brachyrhynchus*. ('Pink-footed Goose.') Europe, N. Asia: Punjab (rare)?

(403) *Bernicla ruficollis*. (*Anser ruficollis*; 'Red-breasted Goose.') N. Asia, chiefly: rare in N. India.

(404) *Cygnus musicus*. (*Cygnus fesus*; 'Hooper Swan.') N. Europe and Asia; N. Africa; migratory: one specimen obtained in the valley of Nepal.

(405) *Casarca rutila*. (*Tadorna rutila*; 'Ruddy Sheldrake.') Europe and Asia, N. Africa (replaced in S. Africa by *C. Cana*): very common in India.

(406) *Tadorna vulpanser*. ('Common Sheldrake.') Europe, Asia, N. Africa: common in the Punjab; not rare in Lower Bengal.

(407) *Spatula clypeata*. (*Anas clypeata*; 'Shoveller.') Circuit of northern regions, N. Africa: tolerably common in India.

(408) *Anas strepera*. ('Gadwall.') Circuit of northern regions; Barbary: tolerably common in India.

(409) *Anas acuta*. ('Pintail Duck.') Circuit of northern regions, Barbary: very common in India.

(410) *Anas boschas*. ('Wild Duck.') Circuit of northern regions, Barbary: in India confined to Sindh, Punjab, and the Himalaya and its vicinity; replaced Southward by *A. Pæcilorhynchos*.

(411) *Anas querquedula*. ('Garganey.') Europe, Asia, N. Africa: very common in India.

(412) *Anas crecca*. ('Teal.') Europe, Asia, Barbary: common in India.

(413) *Anas penelope*. ('Widgeon.') Europe, Asia, N. Africa: common in India.

(414) *Fuligula ferina*. ('Pochard.') Circuit of northern regions, Barbary: common in India.

(415) *Fuligula nyroca*. ('Ferruginous Duck.') Europe, Asia, N. Africa: common in India.

(416) *Fuligula marila*. ('Scaup Duck.') Circuit of northern regions: Punjab, Sindh, Nepal.

(417) *Fuligula cristata*. ('Tufted Duck.') Europe, Asia, Barbary: common in India.

(418) *Clangula Glaucion*. (*Fuligula clangula*; 'Goldemeye.') Circuit of northern regions N. Africa: Sindh, Punjab.

## BIRDS NESTS ROCKS OF KARANG BOLLONG.

(419) *Mergellus albellus*. (*Mergus albellus*; 'Sineu') Circuit of northern regions; W. Asia, Sindh, Punjab, Oudh; apparently not rare along the Punjab rivers.

(420) *Mergus merganser*. ('Goosander.') Circuit of northern regions: not rare in the Himalaya; rare in Central India (*M. orientalis* of Gould.)

(421) *Podiceps cristatus*. ('Great-crested Grebe.') Europe, Asia, all Africa, America; the Australian barely separable: Himalaya, Bengal Sunderbans. Perhaps commoner than generally supposed in India, from its secluded habits and the great difficulty of procuring specimens.

(422) *Podiceps philippensis*. (*P. minor*; 'Little Grebe.') Europe, Asia and its islands, N. Africa: very common in India.

(423) *Phalacrocorax carbo*. ('Common Cormorant.') Circuit of northern regions, Barbary: common in the Himalaya; rare in Central India.

(424) *Sylochelidon caspia*. (*Sterna caspia*; 'Caspian Tern.') Warmer regions of the old World generally, Australia (*S. strenuus*, Gould): not rare in parts of India; but doubtful as occurring in Lower Bengal.

(425) *Sterna paradisea*. (*Sterna Dougalli*; 'Roseate Tern.') Europe, Asia, Africa, America, Australia: coasts of India.

(426) *Sterna hirundo*. ('Common Tern.') Europe, Asia, Africa: S. India, Ceylon.

(427) *Hydrochelidon indica*. (*Sterna leucoparica*; 'Whiskered Tern.') Europe, Asia, Africa, Malay countries; very common in India.

(428) *Gelochelidon anglica*. (*Sterna angelica*; 'Gull-billed Tern.') Warmer regions of the old World, extending also to America; Java: common in India.

(429) *Sternula minuta*. (*Sterna minuta*; 'Lesser Tern.') Northern hemisphere; replaced in S. America and Australia by nearly allied species: common on the west-coast, and in parts of S. India.

(430) *Anous stolidus*. (*Sterna stolidus*; 'Noddy Tern.') Of general distribution, over the warmer parts of the ocean: common in the Indian seas.

(431) *Onychoprion fuliginosus*. (*Sterna fuliginosa*; 'Sooty Tern.') Very generally distributed, like the last; Bay of Bengal.

(432) *Xema ridibunda*. (*Larus ridibundus*; 'Black-headed Gull.') Europe, Asia, N. Africa: not rare in India, but less common than the nearly allied *X. brunneocephalus*.

(433) *Larus fuscus*. ('Lesser Black-backed Gull.') Atlantic, Mediterranean, Red Sea, Indian Ocean, Cape of G. Hope, N. Zealand, Kabul (Burnes), Bay of Bengal.

(434) *Procellaria hæsitata*. ('Capped Petrel.') Indian and southern oceans: a rare straggler in Britain, that has been obtained once only.

(435) *Puffinus obscurus*. ('Dusky Petrel,')

Tropical and S. Seas; Australia; rare northward.—*Cal. : Rev. : No. IV. March, 1857.*

## (436) BIRDS NESTS ROCKS OF KARANG BOLLONG.

The district of Karang Bollong is situated in the residency of Bagelen, division Ambal, on the southerly sea coast between the rivers Chinching-golong and Djétis, both of which have their embouchure in the sea.

Generally speaking the place may be considered healthful. The thermometer (Fahrenheit) is found, as a mean, in the morning at 6 o'clock from 70° to 74°, at noon from 82° to 85° and in the evening at 6 o'clock from 77° to 79°.

The population of the district Karang Bollong consists of 4000 able bodied men, who find their livelihood by gathering birds nests, in the cultivation of sawa and in fishing. The women on their part keep themselves busy in weaving cloths, which are everywhere in good demand, and are much sought for in the capitals on the residencies Surakarta and Djekjarta. Karang Bollong furnishes annually an important produce of birds nests, but it is less known in what manner the collection is made and with how much danger to life it is attended. For this reason we have deemed it not inappropriate to give a description of it here as exact as possible, commencing from the time when the collections begin.

The gathering of the birds nests takes place three times a year under the name of Uduan kesongo, tellor and kapal. The first begins in the end of April, the second in the middle of August, and the third, in December. The yearly produce is commonly between 50 and 60 piculs.

When the time for the gathering approaches the heads come together with the persons they employ before the residence of the overseer, who then, in the presence of the Wodons, Mantre and the writer, fixes the amount destined for the procuring of buffaloes, he-goats, rattans, and torches, as well as the distribution of opium, incense and atat.

After all this has been done, a servant is sent to the Goa Nogosarie accompanied by the head men of this cliff. The Goa Nogosarie is the most accessible, provided the sea is not too rough. Six nests are then ordinarily collected to be compared with the sample of the previous year and to judge if the collection can take place or not.

If the head men consider that the nests are fit to be collected, the people then send for the Wayang and Toppeng, and the overseer makes further regulations with the head men of the cliff, for what is necessary for offerings and feasts.

According to old custom, a thursday is always chosen to make a beginning with the preparation of what is needed for the feast, so that on this day the people occupy themselves with cleaning

## BIRDS NESTS ROCKS OF KARANG BOLLONG.

the ballang, the cliff which is situated at the mouth of the river Tjintjing Guling.

The next morning (friday) the buffaloes are killed. Two hours afterwards they take some pieces of flesh, tongue, entrails, &c., from the slaughtered animals, and place them on small bowls woven of bambus called sadjen. They are then offered to Bollong Watu Tumpang and near the watch houses of the cliffs at Dabar, Gedee, Wale, and Nogosarie; while at the cliff of Medjengklek a he-goat is offered with incense. This festival must, by old custom, always take place on a friday, which by the natives is called Ngaderan. In the afternoon of the same day a Wayang is performed in the Bollong, generally a piece of seven acts: while the necessary flowers, fruits, ointments, sir, pinang &c., and what is further required for the offerings, are prepared by the Tukan Kembang. All these materials are placed on the before mentioned bambu bowls, and in the evening at  $\frac{1}{2}$  past 5 o'clock, are brought by a servant into the Bollong near the Seroot tree. The origin of this tree is ascribed to a Javanese named Kiai who is buried there and above whose grave the tree has risen; and now the superstition of the natives declares that the tree has sprung from the navel of the dead. They likewise make offering on the burial place, at the waringin tree, and in the room, the pantry, kitchen and other places in the dwelling of the overseer.

After the wayang-players have returned from the Bollong, the bed placed near the entrance of the godown, known under the general appellation of devils-bed or bed of Nyai Ratu Kidul (which has existed from time immemorial) is put in order by the Tukan Gedong and ornamented with some silk and other cloths. Nobody but this woman is allowed to do this. Every thursday during the time of the collection this bed is cleaned and offerings are made to it.

After everything has been made ready the small lamps are lighted and the small bambu bowls with flowers, fruit, &c. are placed with particular marks of honor by the Tukan Gedong before the bed on a small couch made for the purpose. At the same time she says in high Javanese, as if addressing some distinguished person "By order of Mijneer (meaning the overseer) I here bring wherewithal for you alone to eat." After this speech the Tukan Gedong, herself answers "Yes, mother, Tukan Gedong, say to father Mijneer (the officer) that I returned my thanks for the food which he has sent me."

After this ceremony is finished the Tukan Gedong remains sitting on the bed, and further asks Nyai Ratu Kidul (who is supposed to be present in the bed) "if it be agreeable to her that the birds nests should be collected, and if it shall take place without mischance," which request is ordinarily answered with "yes" (ingee.)

During this time the wayang is kept up till the next morning.

The following morning (saturday) the heads of the cliffs Dabar and Gediego, with the persons whom they have employed, in their gangs, with the ladders which have been prepared some days before, and accompanied by the Gedeks and Sentonos for each cliff, in order to make further preparations for a commencement; while during all the day the toppeng play is maintained.

The cliffs Walo and Nogosarie are visited eight days later, and Medjengklek two days after that. He enquired what could be the reason for visiting these cliffs latest but no explanation could be given to him. In the evening the toppeng-play being finished, the so called Karang Bollong feast begins, on which occasion the gamilang and two or three dancing girls make themselves heard. At the first seven acts the dancing girls turn their heads towards the birds nest warehouse in honor of Nyai Ratu Kidul, and it is a general custom in the district of Karang Bollong wherever a feast is given to dedicate the first seven songs to the honor of Nyai Ratu Kidul. So soon as the wedons, mantre, writer, the head of the cliffs with their people, and some heads of the dessas, are met, they sit down on a mat in a circle to dine. The writer places himself at the head of this table and proposes different toasts to the success of the approaching collection. After the guests have satisfied themselves, opium is offered to every person present. The company enjoy themselves some with dancing to the music of the Gamelang, some with opium smoking, while others occupy themselves with chewing serree, and this continues till midnight, when the feast ends.

After the feast (on sunday morning) the head men take their departure for their rocks, and, if the sea is not too rough, the ladders are joined in order to reach the entrance of the holes that they may collect six birds nests, which, from produce, are again compared with the musters. The harvest is then arranged. But if it should be found that the nests are not yet ready to be gathered, further preparations are stopped in order that the swallows may not be disturbed. If it is found that the nests are of the proper bulk, the work is continued by making stages and ladders and fastening them to the rocks into which the collectors have to descend. All these operations being completed in five or six days, the inhabitants of the nearest dessa go to the cliffs Dabar and Gedee with the men belonging to these cliffs, accompanied by gandeks and sentonas who carry with them the requisite bags to contain the nests which may be gathered.

The number of collectors for the first day is limited to 80 or 90 persons for each of the two cliffs, and this number afterwards diminishes as the nests are gathered. When the bags are

## BIRDS NESTS ROCKS OF KARANG BOLLONG.

filled they are brought to the godown under the direction of Guru. On arriving there, a sedeka is given, consisting of red and white huber, and this feast is regulated by the collectors of the day for each cliff. After the priest has spoken his benediction over it and the dishes have been eaten, the nests are weighed and stored in the godown on a flooring of plank made for them.

The work of the remaining cliffs Wollo Medjiengklek and Nagosarie is nearly the same, but the collection at the first two places is made by the people employed without any payment on account of the smallness of the produce. With respect to the last, sixty or seventy persons are ordinarily employed, and 57 to 60 rupees copper is paid for each collection to the head men. The sum is divided amongst the bekels and the people. On account of these cliffs being situated at about five miles distance over very difficult roads, the birds nests are kept and watched till the next morning in a bamboo house, called Kongsie, made near the watch house of the cliff. They are afterwards brought to the godowns for which each bearer receives 5 cents, a sogo of opium of  $\frac{1}{4}$  sikar weight. A Sikar being a half cent or the 2 hundredth part of a rupee or gulden (guilder.)

The collection of the nests necessarily depends altogether on the state of the sea. On the top of the mountain Kuda a flagstaff has been erected for this reason, and when a white flag is hoisted it is a signal that the sea is calm, and that the caves can be approached, but if a black flag be shewn it is a signal that the sea is too rough. Each collection from all the caves is finished in twenty-four days. The principal birds nest cliffs are those described above, and they extend from the east to the west along the Karang Bollong south cape. Between these there are some smaller cliffs, the produce of which is of little or no importance.

The collection of the nests is attended with much difficulty and sometimes even with danger to life, because the apertures are situated at the foot of the rocks and are consequently on a level with the surface of the sea, so that the water washes in and out of some of the caves. Hence when the sea is somewhat rough it is impossible to reach the apertures, much less to enter them. In order to form a just idea of the dangerous work which must be performed by the collectors the following is an exact description of it.

To enter the caves you descend one precipice of two hundred feet, nearly perpendicular, by means of one, two or three rattan ladders (according to the greater or less height) which are 5 inches broad and each 77 feet long. The lateral or principal ropes are composed of wild rattans twisted together to a thickness of two inches, and having wooden steps two inches thick and thirteen inches distant from each other. The upper end of the ladder is well fastened to

a strong tree by black ropes and the lower end is placed on one of the rocks.

In order to reach one of the caves, they make use of two rattans each one hundred and eight feet long; but in some cliffs, bambus are used 12 to 18 feet long which are placed one above the other—that they may steady themselves by holding the upper when walking along the under. The entrance of the caves is about 43 feet broad, more or less, and 30 high. The interior is from 60 to 114 feet broad and from 420 to 480 high. The bottom of most of the caves is washed for about one quarter of its length by the sea three, four or more feet in depth. The whole of the interior appears to consist of limestone. In the caves are stages, made of bambus which are bound fast with ropes to the walls of the rocks on which the collectors stand. It often happens, in consequence, that the cliffs on which the ropes of the stage are fastened become loosened and the whole stage is precipitated, which sometimes occasions a loss of life. Most of the nests are taken from the wall by the hand, and these which are on the roof, by an iron hook fastened to a long bambu.

The swallow named lawet, has a compressed head, which, however, with its thick and rounded feathers appears large in comparison with the body. The beak is broad and wide with a black awl-shaped small point bent downwards. The eyes are black and tolerably large, and the tongue arrow shaped. The throat is very short as well as the bones of the wings and feet. The feet consist of four toes of which three are in front and one behind. All the toes have black, curved, sharp, and tolerably long claws, so that the bird can every where lay fast hold of the rocks and cliffs. The tail is almost as long as the whole body. When the throat, the wings and the head are spread out, the bird has a circular appearance. The colour is greyish black inclining a little to green. On the back near the tail to the belly the blackish passes into mouse-colour. The breast is bluish.

Besides these, some other species called lintye inhabit some caves. These are somewhat smaller, and have a white breast. In other respects they agree completely with the lawet. The nests which they make are constructed of grass stalks. They are, however, of the same form, and are as artfully made as the others, but are without the least value. The residence of these swallows lintye in the caves, contributes greatly to the injury of the caves, for which reason they are destroyed as much as possible at each gathering.

On the walls of the rocks, the birds build their nests in horizontal layers close to each other. They place them at different heights from 50 to 300 feet, as they find room, and leave no holes or suitable space open, provided they are clean and dry; for when the walls prove damp they forsake their nests.

the sea attains a high level, which is usually accompanied by a strong surf beating against the cliffs, a percolation of water is caused which is in the highest degree prejudicial.

In the mornings at break of day the birds fly out with a great noise to seek their food, to the neighbouring places in the east monsoon or dry season, but in the west monsoon or rainy season, they do not go far. They return to their caves about 4 o'clock in the afternoon. They feed upon different kinds of insects, hovering above the stagnant waters, for which their wide open beak is very usual.

Their greatest enemies are the birds ulang and alap alap, who pull the young swallows out of the holes and seize many as they fly out of the caves.

They form the nests, by returning the strongest and best fragments of the food which they have eaten.

When the nests have been all plucked, the entrances are closed with bambu fences, the doors are sealed, and the rattan ladders are brought back to the store house.

The nests in the store house are, some days afterwards, weighed, and packed in hampers (geboks, each 25 caties), made very tight with cross ropes, and sealed with the stamp of the overseer. Pieces of paper are placed on each hamper, with the number and the nett weight of the nests written on it.

All this having been done, the hampers are surrounded with cocoanut leaves, prepared in the manner of kadjang mats. Every two hampers are then made fast to a piece of bambu (pikol an) provided with two props, in order that, when resting on the way, the hampers may not touch the ground. They are besides covered with pinang bark so that when it rains the water can run off. Finally they are all sent to Surakarta in order that they may be there sorted.

The evening before the birds nests are sent off another feast is given, and on the following morning, all the coolies depart with their hampers for Surakarta amidst the playing of the gamelang and shouts of hurrah.—*Journal of the Indian Archipelago*, N<sup>o</sup> III, September, 1847, page from 101 to 108

(437) BISMILLAH, means literally, in the name of God, and Mahomedans never commence eating without using it. It is often used by them also, in commencing a book or used in rising or sitting down.—*Herk.* Bismillah irruhman-*irruheen*. In the name of God the merciful, the compassionate, are words first taught to Mahomedan children, at the age of four years, four months and four days, with certain ceremonies.—*Herk.*

(438) BLAKANG MATI. A barren island, near Singapore, about 2½ miles long, and 308 feet in height.

tree, a native of mountainous parts of the Circars. The wood of this tree is white, close grained, and durable, the Natives employ it for a variety of purposes.—*Rohde M.S.S.*

#### (440) BLEACHING.

Nikharna or khumbi kar- | Nana padam, TEL.  
na, HIND. | Salavy<sup>n</sup> punnookiradoo.  
TAM.

In India there is but little occasion for the use of powerful chemical agents, the agency of light being sufficient. After the substances present in goods which oppose the bleaching process are removed by scouring in an alkaline ley, natives usually have recourse to dunging Cloths which are to be bleached and steaming them over the mouth of an earthen pot set in a clay fire place, but little science enters into the process and generally the goods suffer much from the water in which they are scoured being over charged with lime.

It will be remarked by all who have paid any attention to the matter and who have had opportunities, that bleached cloth, particularly in tents, is far less durable than that which has merely had the dressing and filth *thoroughly* removed by washing, this is easily explained as cotton goods have a certain resinous substance in them that obstructs the absorption of moisture. Besides the removal of this, cloth sustains much damage from the abuse of the caustic ley bath; it may be remarked that cloths should be scoured more than once at intervals during the process of bleaching, as many of the substances cannot be removed but after exposure to the light and air.

Wool also is protected by a peculiar varnish exceeding three per cent of its weight, which must be removed by scouring, *warm* hot boiling water must be employed, wool is further bleached by sulphuring either in close chambers in which sulphur is burnt, or by the sulphuric bath; in either case, it acquires a brittleness which must be removed by washing in soap and water.—*Rohde M.S.S.*

(441) BOA, or BOE, sometimes called Poam by the people of Malabar. This wood is much like the timber called in Ceylon Palari, or Palis, and Irambu, or, as known by the English name iron-wood. It is strong, heavy wood, and is considered durable. It grows from twenty to thirty feet high, and from twelve to thirty inches in diameter.—*Edye. M. and C.*

(442) BOATS, SHIPS &c. The native vessels of the coast will take to Bombay about two large and three small spars for a cargo, and a raft of three or four in two at the proper season of the year. Should the spars be required to be sent to Calcutta, or to England, a large mast-ship, with a raft-port at least three feet square, would be required; this would be expensive, and in India difficult to procure.—*Edye. M. and C.*

A description of the various Classes of Vessels constructed and employed by the Natives of the

Coasts of Coromandel, Malabar, and the Island of Ceylon, for their Coasting Navigation was first given by John Edye, Esq., late Master Shipwright of His Majesty's Naval Yard at Trincomalle, afterwards Department of the Surveyor of the Navy, and was communicated by the late Major-General Sir John Malcolm, G. C. B., K. L. S., M. R. A. S., &c., &c. to the *Journal of the Royal Asiatic Society*, and read 1st of June, 1833.

The following Paper having been referred by the Council of the Royal Asiatic Society to Sir John Malcolm, for his opinion as to its eligibility for insertion in the printed transactions of the Society, was returned by that distinguished and lamented individual, with a letter of which a copy is subjoined, and which will be found to point out, in a very satisfactory manner, the practical value of Mr. Edye's communication.

"Before I comply, he says, with the desire of the Council to report on Mr. Edye's Treaties on Indian Vessels, it may be useful to explain how it came into my possession.

"When on a visit to Chatham, Mr. Edye, who is now employed in His Majesty's dock-yard at that place, showed me this manuscript; and deeming it very curious, I beg he would allow me to present it to the Royal Asiatic Society, which might, I thought, consider it worthy of a place in its transactions; not only as it exhibited the actual state of the art of ship-building in India, but on account of the evidence it contained of that art being at the same stage at which it now is, at a period of the most remote antiquity. Mr. Edye's manuscript appeared to me to possess more value from the remarkable fact, that many of the vessels of which he gives us an account illustrated by correct drawings of their construction, are so admirably adapted to the purposes for which they are required, that notwithstanding their superior science, Europeans have been unable, during an intercourse with India of two centuries, to suggest, or at least to bring into successful practice any improvement. I may adduce the Masula boats, on the coast of Coromandel, in proof of this assertion; and, to my knowledge, both talent and skill have laboured in vain to improve the shape and construction of those vessels.

"The Council having referred this paper to me, I shall shortly state its contents, and my opinion of its value.

"Mr. Edye, by a residence of five years in India, as His Majesty's Master-shipwright in Ceylon, had singular opportunities of becoming perfectly informed on the subject of which he treats in this memoir. He describes in a clear and concise manner the various vessels of the coasts of Coromandel, Malabar and Ceylon;

Catamarans.....of Ceylon, the Malabar and Coromandel coasts, &c.

Canoes.....of Point de Galle and the Malabar coast.

Jangar .....of the Malabar coast, for rivers  
Pamban Manche...Snake Boat of Cochin.

Bander Manche...Boats used to load ships and carry goods on the coast of Malabar.

Masula Boats.....Used chiefly at Madras in landing and discharging cargoes, and carrying passengers to and from ships in the roads.

Mangalore Manche } These are coast boats, of  
Calicut Manche... } construction suited to  
Panyani Manche... } the places from which they are named.

Patamar.....Vessels employed in the coasting-trade of Bombay to Ceylon.

Arab Dow.....Vessels employed in the trade between the Red Sea, the Arabian coast, the Gulph of Persia, and the Indian coasts of Cutch, Gujerat and Malabar. These Dows are also used in the Persian Gulph, for the purposes of war and piracy. They are always manned by Arabs.

Baggalah, or } These vessels trade from  
Budgerow..... } Cutch, Gujerat, and the Malabar coast to the Gulph of Persia, the coast of Arabia, and the Red Sea. They are Indian vessels, and manned with Indian seamen, called Lascars.

Doni.....A vessel used in the coasting trade of Coromandel, from which they often carry cargoes to Ceylon and the Gulph of Manaar.

Boatila Manche ...Used in the Gulph of Manaar and the southern parts of the Peninsula, and trading from these to Ceylon.

"The shape and materials employed in the construction of the vessels are minutely stated by Mr. Edye; and the well executed plans and sections of each class, by which their descriptions are illustrated, will, I am assured, attract the particular notice of the Council; to whom I have no hesitation in stating, that I deem Mr. Edye's Treaties highly valuable; and am of opinion, that while it merits attention from those engaged in the study of nautical science, it must be acceptable to antiquarians and philosophers, who seek, by comparisons of the works of man in various ages to draw conclusions as to the

of science merits more of their consideration than that which enabled him to have intercourse with distant nations, and through such means to advance knowledge and civilization!

“JOHN MALCOLM.”

#### MR. EYDE'S PAPER.

Among all the numerous vessels of every class and description which traverse the ocean, there is a peculiarity of form and construction intended to meet the various localities of the ports or seas in which they are navigated; and perhaps in no part of the globe is this principle more fully displayed than in the Indian Seas, and on the coasts of the Southern Peninsula of India, including the Island of Ceylon, where the nature and change of the season, the monsoons, and the navigation of the seas and rivers, are singularly well provided for by the truly ingenious and efficient means adopted by the natives in the formation of their rude, but most useful vessels. I shall endeavour to describe these more explicitly, with the aid of the sketches and designs, the correctness of which I have been most scrupulous to ensure.

#### (443) CATTAMARANS.

The first which I shall describe, will be the Catamarans of the Island of Ceylon, which like those of Madras, and other parts of the coasts of the Peninsula, are formed of three logs of timber, and are used by the natives for similar purposes; the timber preferred for their construction is of the dup wood, or *cherne marum* (piney tree). Their length is from twenty to twenty-five feet, and breadth two and a half to three and a half feet secured together by means of three spreaders and crosslashings, through small holes; the centre log being much the largest, with a curved surface at the fore-end, which trends and finishes upwards to a point. The side-logs are similar in form; but smaller, having their sides straight, and fitted to the centre-log, as will be better seen and understood by the accompanying sketch.

These well known floats are generally navigated by two men; but sometimes by one only, with the greatest skill and dexterity; as they think nothing of passing through the surf on the beach at Madras, and at other parts of the coast, while boats of the country could not live on the waves; and at sea, they are propelled through the water to ships on the coast, when boats of the best construction and form would swamp. In the monsoons, when a sail can be got on them, a small outrigger is placed at the end of two poles, as a balance, with a bamboo mat and yard, and a mat or cotton cloth sail, all three parts of which are connected; and when the tack and sheet of the sail are let go, it all falls fore and aft, alongside; and being light, it is easily managed. In carrying a press of sail they are trimmed by the balance lever by going out on the poles, so as to keep the log on the sur-

face of the water, and not impede its velocity, which, in a strong wind, is very great. They are frequently met in with ten or fifteen miles off the southern part of the Island of Ceylon, and will convey any letter or despatch to the shore with safety: but I cannot say much about its dryness, as the man who takes it has nothing but a pocket made from the leaf of the arca-tree (*A. catechu*, Linn), which is tied round his waist, and is the only article about him. These people may be considered almost amphibious, and are the persons who are employed in the pearl-fishery. They are said to remain under water for fifty minutes; but this I have never heard from themselves, or could find to be correct, as five minutes is the greatest time that has come to my knowledge. In an account of the Ceylon Pearl Fisheries, by Captain James Stuart, inserted in the *Trans. R. A. S.* Vol. III. Part 3. the author states, from personal observation, that the longest time which the divers can remain under water is from eighty-four to eighty-seven seconds. They certainly think nothing of going down to a depth of forty feet; and will bring up a rupee even, if thrown into the sea at that depth.

#### (444) THE POINT DE GALEL CANOE, OR MARKET BOAT,

Is a Boat formed from a single stem of dup wood, or piney varnish-tree. They are from eighteen to thirty feet in length; from eighteen inches to two and a half feet in breadth; and from two to three feet deep; exclusive of the wash board, which is about ten inches broad, and sewed to the gunwale by coir-yarns, with loose coir-padding on the joints, in the same manner as the other boats used in India are sewed together, which will be more fully described hereafter. These boats are fitted with a balance log at the end of the bamboo outrigger having the mast, yard, and sail, secured together; and, when sailing, are managed in a similar way to the Catamarans. Vessels passing the southern part of the Island of Ceylon are generally boarded by these boats even at the distance of twenty to twenty five miles from shore. They will sail at the rate of ten miles an hour in strong winds, which are generally prevalent there; and, with a crew of five men, will carry a cargo of fruit, fish, and vegetable, which are the greatest luxuries to passengers, on making the land after a long voyage from England, Bengal or Bombay. The details of these very interesting vessels will be better understood by reference to the Sketches in Plate II. A model of one of these curious boats is in the Museum of the Royal Asiatic Society to which it was presented by Mrs. Perring. The society is also in possession of a model of a boat having two outriggers, with balance logs, used by the natives of some of the islands in the Eastern Archipelago: this model

was received from H. J. Donis, Esq., P. M. R. A. S., His Netherlands' Majesty's Resident at Sourabaya, in Java. The natives of New Holland appear to use a similar contrivance, but of a more simple construction, as exhibited in models in the Society's possession. The Rev. Richard Walter, in his account of Lord Anson's Voyage, gives a minute account, illustrated by an engraving of what he terms "a flying proa," used at the Ladrone Islands; which is the same, in most essential particulars, as the vessel described above by Mr. Edey. (Vide Walter's Account of Anson's Voyage round the World 4to. London, 1748 p. 339.)

(445) CANOE OF THE MALABAR COAST.

From Cape Comorin to Calicut, on the western side of the Peninsula, the coast abounds with fish, which is generally taken with the hook and line by the natives of the fishing villages, in a small canoe; the best description of which is formed from angeley-wood; *Anjele*—*Artocarpus hirsuta* (?) But the inferior sort of *cherne maram*: they are cut out from the solid tree, and are from eight to twenty feet in length, and from one and a half to two feet in breadth; the depth being about one, or one foot and a half. They are managed with much dexterity by the natives, with a scull-paddle. On the backwater of Cochin, and on the river's mouth, they are employed in great numbers in taking the saire fish or country salmon, &c. The largest sort of boats are used for the conveyance of rice and merchandise on the numerous rivers which disemogue themselves into the back-water, to the extent of 150 miles, parallel to the sea-coast. At times these boats are converted into the

(446) JANGAR,

or Double Platform Canoe, by placing a floor of boards across two boats, with a bamboo railing which extends from ten to twelve feet fore and aft, and sixteen feet long; and when these boats are thus formed into rafts, cattle and burthensome articles are conveyed across the rivers; as also the native regiments, with all their followers, horses, bullocks, baggage, bandies (carts), &c. It appears somewhat probable that the idea of the pontoon now in use at Chatham was taken from these vessels, as those constructed by the engineers there perfectly resemble such as are used by the natives in India.

(447) PAMBAN MANCHE, OR SNAKE BOAT OF COCHIN,

is a canoe of great length: they are used by opulent natives and Europeans, as boats for the conveyance and despatch of persons on the numerous rivers and back-waters, particularly on that between Cochin, Allipey, and Quilon, which is about eighty miles southward; and on that which runs to Rappact and Trichoir; the former place being about twenty, the latter about sixty miles to the northward. These boats are from thirty to sixty

feet in length, without any regard to breadth or depth, as they are worked from the solid tree. The broadest do not exceed three feet. Those of the Raja and officers of state are very handsomely fitted up, and carved in the most fantastical manner: they are made very neat, and even splendid, with painting, gilding, &c. The largest boats are sculled by about twenty men, double-banked; and when pressed, their velocity is surprising, as much as a mile in five minutes. I have myself been sculled, in one of them, a distance of forty-eight miles in six hours. These boats are peculiarly adapted to the rivers; for it frequently occurs, that in the dry season there are sand banks perfectly dry, nearly a hundred yards in breadth, over which they must be drawn by the strength of the few men who are in them; the smaller size having only six rowers and a coxwain. Those natives who can afford the expense, have the cabin neatly fitted up, with venetian blinds on the sides, but generally the cuscus, or grass-mat, is substituted. This boat is formed from the angeley-wood, which is very durable, if kept oiled.

(448) COCHIN BANDAR-MANCHE, OR CANOE OF BURTHEN.

These canoes are cut and formed from the largest and softest timber of the forest. They are from twenty to fifty feet in length; their breadth and depth being proportioned to the full size of the tree so as to reduce its dimensions as little as possible. They will carry about eighteen tons burthen, and are made from three to five inches thick at the bottom; but at the top of the side, or gunwale, about one and a half to two inches, with a proportionate increase of thickness at the extreme ends, to protect the end-grain of the wood, and withstand any shock that they may meet with. At the distance of about five feet on the inside there are ribs about six inches broad, projecting about two inches from the side of the boat, for the purpose of giving support and strength to the body of the canoe. These boats may be considered valuable for the service of the port at which they are used; and notwithstanding their heavy appearance, they are very buoyant, and go very fast through the water. In one of about thirty-five feet long, with six men and a tindal (coxwain). I passed the Minden's (the Admiral's ship) barge, which had twelve men on board; and in a distance of four miles to that ship's anchorage, I gained on them by time about twenty minutes, although there was a strong sea-breeze and swell against us.

At Cochin, these boats are used for the purpose of conveying various articles of burthen and water to the ships in the roads. This is well known to the homeward bound ships from Bombay, and those bound from the Red Sea and Arabia to Calcutta; as they generally call off this port, for supplies of every sort. Two

of the larger size were sent, by order of Commissioner Upton, to Trincomalie, for the use of the dock-yard; and after being constantly used during four years, for the purpose of carrying stones, bricks, sand, coral, &c. across the bay, they were left, when the establishment was broken up in a sound and complete state; which circumstance may be attributed to their having had copper sheets put on their bottoms, to protect them from the worms. The expense of each canoe was about eighteen pounds sterling; and they would convey from twelve to twenty tons, each boat.

It would be worthy of consideration, and a great service to the navy, to have one of these boats, with a native crew, attached to each ship; for the purpose of saving the seamen, and ships-boats, from exposure to the intense heat of the surf, the bad effects of which are so very sensibly felt by Europeans at all times.

#### (449) THE MADRAS MASULA MANCHE,

Is formed with a flat bottom, for the purpose of taking the beach in the surf, when European boats cannot approach it. These boats are beached in the third surf; and taken most completely out of the water, on the immediate receding of the swell by natives.

The planks which form these boats are sewed together with coir yarns, crossing the seams over a wadding of coir, which presses on the joints, and prevents leakage. By this peculiar means of security, the vessel is rendered pliable, and yields to the shock which she receives on taking the ground; whilst boats with framed timbers and planks, nailed or trenail-fastened, would be broken to pieces, from the heavy surf, that at times runs as high as from six to ten feet. The Catamaran can be kept in attendance, as a life preserver, in the event of any accident to the masula-boat, by upsetting; or in case of any of the Europeans being washed out by the surf.

The masula-boats receive their cargoes and passengers from the ships outside the surf; and land them in perfect safety, provided the crew be treated with civility; if otherwise, they will not fail to moisten the offender, to such a degree as to shew the passengers that they are in their power, and make them objects of derision to the men on the beach. These boats are rowed by twelve men, in double banks, with bamboo paddles; that is, a board about ten inches broad and fourteen inches long, fixed at the end of a bamboo. They are steered by two tindals (coxwains) and two men are constantly kept to bale out the water; from which employment they are promoted to the paddle, or bow-oar; after which they fall off, in rotation, to be a tindal or steersman. The steersman gives time by a song, which is sung by all the boatmen; and according as its modulations are slow or quick, the oars are plied. These modulations are regulated by the waves, as they may be slow or rapid, in succes-

sion. I remember, on one occasion, when a passenger of rank showed impatience at this noisy song, the boatmen were desired to cease; but the steersman refused compliance with the order, saying, that without his song he would not be answerable for the safety of the passenger.—(Note by Sir J. Malcolm.) The dimensions of the masula-boat are from thirty to thirty-five feet in length, ten to eleven feet in breadth, and seven to eight feet in depth: the details of their form will be understood from the drawing.

#### (450) MANGALORE MANCHE,

Is a flat bottomed boat of burthen, about twenty-five to thirty-five feet long, six to seven feet broad, and four to five feet deep. It is formed to meet the river, which is very shallow and flat; and to land the cargoes of the patamars, which are discharged and loaded at the mouth of the rivers. These boats are sewed together similar to the masula-boat and other native vessels: they are forced along by bamboo poles; as the water is not more than from six to ten feet deep, except in the southwest monsoon, when the rapids swell; and the whole of the river is considered impassible; and at this period all the vessels are taken to the shore and laid up.

#### (451) CALICUT MANCHE,

Is a boat very similar to that of Mangalore with the exception only of a raking stem, for the purpose of taking the beach; as the port of Calicut is open to the coast and there is no river. These boats are propelled by the paddle and sail and generally carry eight men: they are much employed in watering and completing the sea-stock of ships homeward-bound; also in loading ships with pepper, timber, &c., for Bombay; and in shipping the produce of the forests of Canara and Malabar, for the naval yard of the East India Company; all of which is rafted off to vessels called dows, boatiles, patamars &c., hereafter described.

#### (452) PANYANI MANCHE,

Is a coasting boat, of about fifty feet long, ten to twelve feet broad, and five to seven feet deep. It is framed with timbers and planks; which are sewed together, as before described. The timbers are about four feet asunder, and on them inside, some few planks are placed as bands and clamps, which are nailed to the frame. These are very rudely put together; and not of much importance, either in form or construction. During the south-west monsoon, or from June to November, they are laid up at Baipur river for safety, and are only used in the fine-weather season. They carry the productions of the coconut tree, viz. coir, [coir is the husk of the coconut (*Cocos nucifera*), from which rope is made.] Copra, [copra is the inside or fruit of the nut, from which oil is expressed.] Cajan, [cajan is the

leaf of the tree (*Corypha umbraculifera*) which is used for coverings of houses; also for books, and various other purposes. Jageri, [Jageri is a kind of sugar, which is made from the toddy or juice of the Palm.] Oil and Arrack, [arrack is a strong spirit, distilled from the toddy taken from the Palm] to Cochin and Mangalore; and, from these parts rice, cloth, salt, &c. These vessels keep along shore and take advantage of the sail in rowing. They have generally from eight to ten men, who are fishermen, of the Mopila caste. A race of Musalmans, descendants of the first Arabian settlers on the shores of the peninsular; and who marrying the daughters of the country, obtained the name of Mápillai, or "sons-in-law," corrupted by Europeans into the above term.

## (453) THE PATAMARS,

Are a class of vessels which may be considered the best in India; as they sail remarkably well, and stow a good cargo. They belong principally to Bombay merchants, and carry on the whole of the coasting-trade to that port. They are grab-built: that is, with a prow stern, which is the same length as the keel; and the dimensions of the large class are seventy-six feet six inches in length, twenty-one feet six inches in breadth, eleven feet nine inches in depth, and about two hundred tons burthen. They are planked with teak, upon jungle-wood frames; and are really very handsome vessels, being put together in the European manner, with nails, bolts, &c. and their bottoms are sheathed with inch-board, and a layer of chunam mixed with cocoa-nut oil and a portion of damar (country resin): this is a very durable substance, and a great preservative to the plank against worms.

Some of the smaller class of these vessels, of about sixty tons burthen, are sewed together with coir, as other native boats are. The small class has one, and the large class two masts, with the lattan sail: the foremast raking forward, for the purpose of keeping the ponderous yard clear when it is raised or lowered. The yard is slung at one third of its length, the tack of the sail is brought to the stern-head, through a fixed block; and the sheet hauled aft at the side, as usual. The haul yard is a pendent and treble block, from the mast head aft to midships; thus acting as a back-stay for the mast's security, together with about two pairs of shrouds. These vessels generally export salt from Bombay to the coast, and take back coir, rice, cocoa-nuts, copra, oil, timber, sandalwood, pepper, and various articles, the production of the coast. They are navigated with much skill, by men of the Mopila caste and other Musalmans; and have a crew of ten or twelve men, and a tindal, who are good pilots and navigators off the coast from Bombay to Cape Comorin; generally speaking, honest and trustworthy; and very respectful to Europeans.

## (454) THE ARAB DOW,

Is a vessel of about one hundred and fifty to two hundred and fifty tons burthen, by measurement; grab-built, with ten or twelve ports; about eighty-five feet long, from stern to stern; twenty feet nine inches broad; and eleven feet six inches deep. Of late years, this description of vessel has been built at Cochin, on the coast of Malabar, most perfectly, in the European style. These vessels have a great rise of floor; are calculated for sailing with small cargoes; and are fully prepared, by internal equipment, for defence, with decks, hatchways, ports, poop-deck, &c., as shewn by the sketch, which, it will be seen, is that of a vessel of war; many of them are sheathed, on two-and-a-half-inch plank bottoms, with one inch board, and the preparation of chunam and oil, as before described, which is called galgal, put between the planks and sheathing-board, causing the vessel to be very dry and durable; and preventing the worm from attacking the bottom.

The worm is the one of the greatest enemies in India to timber in the water, while the white ant is as much so out of it. On the outside of the sheathing board there is a coat of white-wash, made from the same articles as that between the sheathing and planks; which coat is renewed every season they put to sea. These vessels have generally one mast, and a latteen-sail: the yard is the length of the vessel aloft; and the mast raking forward, for the purpose of keeping this ponderous weight clear, in raising and lowering. The tack of the sail is brought to the stern-head, and sheets aft in the usual way; the halyards lead to the taffrail, having a pendent and treble purchase-block, which becomes the backstay, to support the mast when the sail is set: this, with three pairs of shrouds completes the rigging; which is very simple, the whole being of coir-rope.

Several of these vessels have been fitted as brigs, after their arrival in Arabia; and armed by the Arabs for cruising in the Red Sea and Arabian Gulf, as piratical vessels: they are also the class of vessels of which Tippu Sultan's at Onore consisted. When armed, they are too powerful for the Bombay marine brigs. This has never happened, but when in great numbers, and the brigs weak and unsupported.—(Note by Sir. J. Malcolm.) The large dows make generally one voyage in the season, to the southward of Arabia; taking advantage of the north-east monsoon to come down, and the south-west to return with an exchange cargo. They generally bring dates, fruit, preserves, Shiraz-wine, and horses; and take back rice, coir, canvas, cocoanuts, oil, timber, damar, &c., various articles of cloth of the country manufacture, and from Bombay. European articles of every description. The trade of this part of the country is very great in those vessels; ex-

tending from Allipey, the southernmost port on the coast of Malabar, up to Bombay: but all the trade to Bengal is carried on by ships which are called "Country Traders," from the Gulf of Persia and Arabia. The Arabs are a powerful, well grown, handsome people, and very acute and intelligent in trade. They usually navigate their ships to Bengal in perfect safety, and with great skill: This was well known to Captain Collier and his officers, of the Liverpool frigate, when they had the trial cruise with Imam of Mascat's fine frigate, in 1820.

(455) THE BAGGALA, OR BUDGEROW,

Navigates the Indian seas from the Gulf of Cutch and is one of the most ancient vessels there to be met with. Their extreme length, from stern to taffrail, is about seventy-four feet, the breadth about twenty-five feet, and the depth in hold eleven feet six inches, with about one hundred and fifty tons burthen. The peculiarity of form and extraordinary equipment of these vessels is said to have been the same from the period of Alexander the Great: they are armed with two guns on the after part or right-aft of the stern for defence against pirates; and have their poop-decks with a round stern: their extreme sections about the centre or middle of the vessel: they are very broad in proportion to their length, with a sharp rising floor: the stern is straight, and rakes very little more than the stern-post. The form of the vessel, however, will be better understood by a reference to the drawing.

These vessels are constructed with timbers and planks, which are nail and trenail fastened, in the most rude and unsafe manner possible. The topside above the deck is barricaded with mats on the outside of the timbers, which run up to about eight feet from the deck; and when they have no cargo on board, this barricade is removed.

They have only one mast; with a huge yard made from two spars, the small ends lashed together, and a latteen sail, the tack of which goes to the sternhead, as in the other vessels before described: they generally trade like the Dows; and are navigated by Arabs and the people of Cutch.

This singular and rude vessel, as well as the Arab Dow, is peculiarly adapted to the coasts of Arabia and the Red Sea, which are subject to periodical winds during which these vessels are navigated with much ease.

(456) THE DONI,

of the Coromandel coast is a huge vessel of the ark like form, about seventy feet long, twenty feet broad, and twelve feet deep; with a flat bottom or keel part, which at the broadest place is seven feet; and at the fore and after-parts of the vessel it breaks into ten inches, which is the siding of the stem and stern-post. The fore and after bodies are similar in form, from midships.

Their light draught of water is about four feet: and when loaded, about nine feet. These rude unshapely vessels trade from Madras and the coast to the Island of Ceylon; and many of them to the Gulf of Manar, as the water is shoal between Ceylon and the southern part of the Continent. They have only one mast, with a long sail; and are navigated from land to land, and coastwise, in the fine season only.

It may not be uninteresting to know the means used, by the people who navigate these vessels, to find the rate of current in the Bay of Bengal, which is very great at the change of the season or monsoon, as much as sixty miles in twenty-four hours. When they are off a port, in a calm, they throw a handful of sand or shells and feathers, in the calm sea; and by the drifting of the feathers on the surface, and sinking of the sand or shells, a calculation of the rate of current is formed, and they anchor off the coast accordingly.

The anchor is made, in the most simple way imaginable, by lashing together three crooked branches of a tree, which are then loaded with heavy stones; and their cable is formed from coir-yarns. In fact, the whole equipment of these rude vessels, as well as their construction, is the most coarse and un-seaworthy that I have ever seen, and far behind those of any other part of India.

(457) THE BOATILA MANCHE,

Of the Island of Ceylon, which navigates the Gulf of Manar, and the southern part of the Peninsula of India. This boat, which is about fifty to sixty feet in length, sixteen to eighteen feet in breadth, and eight to ten feet in depth, has more of the European form than any of the Indian-built vessels that are met with. The after part shews the origin to be of Portuguese construction, as it is very similar to that of many of the boats still in use by the people of that country; which are said to be of the same shape as the vessels in which Vasco De Gama sailed to India.

They have a deck fore and aft; and are built with all sorts of jungle-wood, in a very rough manner, and fastened with nails and bolts. They are equipped with one mast, which inclines forward, and a square lug-sail; also a small bowsprit, at about the angle of 45°, with a sort of jib fore-sail, one pair of shrouds, and a back-stay which completes the rigging. These vessels carry on the trade of the island across the Gulf. The exports are, rice, tobacco, &c. and the imports, cloth. This forms a great part of the revenue of the island, in the district of Jaffnapatam.—*Mr. Edye on the Native Vessels of India and Ceylon, in the Journ. of the Royal Asi. Socy. No. I. July 1834, page from 1 to 14.*

(485) BOATS.

on the Ganges are of various descriptions, the Bugerow, the Boleah, the Panswah.

(459) BOMBAX CEIBA. *The silk Cotton tree*, adorns many parts of the Burmese country. It is one of the largest trees, and its beautiful and soft floss is used for pillows, and thin mattresses by the natives; *Malcom's Travels in South Eastern Asia*. V. 1. p. 187. The juice of the root is aperient and its bark emetic.—*Voigt*.

(460) BOMBAX GOSSYPIUM. Under this name, mention is made by Mr. Rohde of a large beautiful tree, a native of the Circar mountains and cultivated in gardens on many parts of the Eastern coast of the peninsula of India where it bears bright yellow blossoms. The cotton is soft and silky—the wood is soft and of but little if of any use.—*Rohde, M.S.S.*

(461) BOMBAX MALABARICUM Syn. BOMBAX HEPTAPHYLLUM.

Boorooga Chettoo, TEL. | Rueta Semul, also  
Poolamarm, TAM. | Semul, BENG. HIND.

This one of our largest peninsular coast trees, is found every where but is of very great size in the neighbourhood of the Circar mountains where it is often one hundred feet high. Flowering time the end of the cold season, when the tree is generally destitute of leaves it is then covered with bright red flowers. The wool of this species does not adhere to the seeds, and is used to stuff beds and pillows in preference to cotton.

The wood is white and light but watery and spongy and fit for very few purposes, scarcely even for fuel.—*Rohde, M.S.S.*

(462) BORAX. Sub-boras sodæ.

Velligarum, TAM. | Booruc, ARAB.  
Sohaga, DUK. and | Tunkar, PERS.  
HIND. | Paterree, MALAY.

According to Ainslie, borax is found in Thibet, and in Persia, whence it is brought to India; and the Abbe Rochon, in his voyage to Madagascar and the East Indies, informs us that it can also be procured of a superior quality, in China.—*Ainslie's Materia Medica*, p. 6.

(463) BORNEO is divided by the equator into two unequal and extended parts, of which the southern is the larger. This island is the greatest on the globe after that new world, surrounded on all sides by the ocean, which is named new Holland. If we comprise the numerous archipelagoes by which the great land is environed, this group may be said to occupy more than eleven degrees of longitude and about ten of latitude. The geographical position of the principal island is between 7° N. L. and 4° 20' S. L. and between 106° 40' and 116° 45' E. Lon. Its length from north to south will be about 300 leagues and its breadth varying from 250 to 150 leagues. Its superficies has been estimated at 13,342 square geographical leagues; the more exact calculation which Mr. Melvill de

Carnbee has published in *Le Moniteur des Indes* gives Borneo a surface of 12,741 square leagues or 6,992 myriametres; which makes it 2,589 myriametres greater than Sumatra, and 5,723 myriametres greater than Java.

Old documents make known to us that the Portuguese Lorenzo de Gomez was the first of the European navigators who approached the northern part of this island; he arrived in 1518 in the ship St. Sebastien on his route to China. We presume that he gave to the country the name of Burne, but he says that the natives term it Braunai or Brauni. The travellers who have recently penetrated into different parts of the interior, the Dutch Major, Muller, Colonel Henrici, the members of our scientific commission, Diard, S. Muller and Korthals, as well as the Rajah Brooke, assure us that the Dayaks which form the aboriginal population of Borneo, do not use, and cannot even have any idea of a specific name appropriated to the whole extent of a country of which the sea bord is even most often unknown to the savage and wandering tribes who are separated by great distances from each other, and who are dispersed in hordes of small numbers over the vast extent of one of the largest islands in the world. These different tribes are designated amongst themselves by the names which they give to the rivers on the borders of which they have establish their abode; it is thus that all the Dayaks of the great river Dusen (the Banjer of our maps) call themselves Orang Dusen (men of Dusen) and those of the river sampit, Orang Sampit; the manuscript memoirs of Major Muller and of Colonel de Henrici make mention of a great number of tribes designated by the names of rivers which have their mouths on the western coast; in the north of Borneo Mr. Brooke makes mention of Dayak tribes under the names of Sarebus, Sakarran, Lundu, Sibmuw &c. established on the rivers which bear those names.—*Journ. of the India Archipel. Vol. II. No. VI. June 1848, page 365.*

The coal and iron fields of the Balawi or Rajang are more extensive than any yet discovered on the Island. From the river Baram, coal is traced to the upper parts of the Bintulu, and thence southward to the Rajang river, on the left bank of which, at Tujol Nang, there is a seam exposed upwards of thirteen feet in thickness. At different other parts of the river and also in several of its branches coal is found in abundance. From Tujol Nang the strike of the coal is southward across Dragon's plain. It is again found in the river Lang Pila (a distance from the former place of about fifty miles) where it is extensively exposed on the surface, and has been in a state of ignition for several years. Iron ore of a quality yielding from

## BOUEIA.

sixty to eighty per cent of iron abounds in the Baluwi or Rajang district, from about forty miles from the coast to the source of the river, or over a district comprising nearly one-half of the extreme breadth of the island. The iron manufactured from the ore of the above district is much preferred to that of Europe by the Malays and other natives of Borneo as being superior. If such be the case it is certainly worthy of notice. If the ore of Borneo, by the rude manner of smelting practised by the Kayans, make better iron than that of England, with all the advantages possessed by the smelting of that country, we must infer that if the science and superior genius of Englishmen were employed in the preparation of iron from the rich mines of Borneo, this valuable metal could be produced cheaper, in quantity greater, and quality superior, to that for a scanty supply of which the trade of Great Britain is dependent on the arbitrary monopolies of Sweden.—*Jour. of the Indian Archipelago Vol. iii. No. iii. Feb. 1849.*

(464) BOS, At the Paris Exhibition of 1855, there were exhibited of *Bos taurus* diverse varieties.

Gour (*Bos cavifrons*);

Buffalo (*Bos bubalus*);

Arni (*Bos Arni*);

Gyal (*Bos frontalis*).

Amongst the animals who infest the forests of Nepaul, is one of the largest of the wild ox tribe known, measuring at the shoulder from eighteen to twenty hands and of great power. The bull is a very ferocious animal, it is called by the Nepaulese the Ghowrie Ghai. The body is of a brownish blue colour to the knee, and from that to the hoof white, with a very formidable pair of horns, about two feet long, and of about eighteen inches in diameter at the roots. From the root of the horns to the back of the neck, a strong oily substance is emitted with a very powerful musky smell. A more formidable animal than the bull there is not to be found in the Nepaul forests; no tiger dares to approach a full grown one, and two of them have been known to drive off a rhinoceros.—*Smith's Nepaul.*

(465) BOUEIA, Meisner: CAMBESSEDIA, Wight and Arnott. *Boueia burmannica*. *Mangifera oppositifolia*. *Roxb. Hort: Bengh, p. 18 Fl. Ind. 1 p. 640. Ed. Carey*; *Manga sylvestris* Rumph. *Hb. Amb. 1, t. 27?*

Mariam also Mai-ten, BURM.

Commonly cultivated by the Burmese. It is a small tree, leaves narrowly oblong lanceolate, obtusely acuminate or cuspidate, leathery, in length 5 inches and  $1\frac{1}{2}$  broad. Stamens, oftenest 4. Drupe the size of a hen's egg.

(466) BOUEIA MACROPHYLLA.

Roomaniya Baitool, MALAY.

This inhabits Malacca.

## BRASS.

(467) BOUEIA MICROPHYLLA.

Roomaniya Taigo, MALAY.

The habit of these two species is different from that of the Burmese one, the leaves more coriaceous, and the secondary veins more distinct. The fruit of both is eaten by the Malays. They have the characteristic acidity, but make excellent pickles. *Cantor.—Ben. As. Soc. Jour. 1854.*

(468) BOSCA TRINERYA.

Mentioned by Roxburgh as a large tree a native of the Circar mountains: the tree is not known nor if it be used in the arts.—*Rhode, M. S. S.*

(469) BOSWELLIA GLABRA.

Googoolapoo chettoo, TEL.

This tree yields a resin, which is used as incense and for pitch in some parts of India. It is a native of the mountainous districts of Coromandel.—*Roxb. Rhode, M. S. S.*

(470) BOSWELLIA THURIFERA. CANARIUM HIRSUTUM C. ODORIFERUM.

Salaec, SANS.; Salai, BENG.; Luban, HIND.

In Telooogo, the tree, Koondooroo, a large timber tree a native of the mountainous parts of Coromandel, Bundelkund &c. said to be the tree producing the frankincense of the ancients.—*Rhode M. S. S.*

The *Boswellia thurifera*, the Frankincense or Olibanum-tree, is very common on the Ajmeer hills, and elsewhere, the wood is cheap and very worthless. The tree yields abundance of gum resin, but it is not gathered or put to use at Ajmeer. The tree is very abundant and the natives of Ajmeer call the resin "luban" from which an excellent clear turpentine might be distilled.—*Gen. Med. Top. p. 192*

(471) BRAHMIN. Ward in his work on the 'Literature and Mythology of the Hindoos,' mentions the confession of faith of a Brahmin, which he gave him, "God is invisible, ever living, glorious, uncorrupt, wise, the ever blessed, the Almighty, his perfections are inconsiderable and past finding out. He rules over all, destroys all, and remains after the destruction."—*Chow-Chow, p. 44.*

(472) BRALLAH, the Malayala name of a tree that grows on the Malabar coast to about eight inches in diameter, and sixteen feet high. It is used by the natives on the coast for boats; and for timbers and knees in larger vessels: it is considered strong and durable.—*Edye, M. and C.*

(473) BRASS.

Pettalie, TAM.; Itarie, TEL.; Peytal, HIND.

The Brass so much used in India for pots by the natives generally is of a very inferior de-

## BRASS.

scription, the workman who forms it with proportions of copper and zinc finding it profitable to employ an undue proportion of the cheaper metal; good malleable brass is found in old pots occasionally, probably from the number of times it has been melted and worked up causing the metals to combine more perfectly and the excess of zinc to be expelled by frequent heatings. In Europe brass was prepared generally by cementation, the fumes from calamine, the ore of zinc acting upon heated copper plates. The best brass may be made by fusing two parts of copper and one of zinc, various proportions being used according to the purpose required.

Copper, Ragi, TEL.		Lead, Sheesham, TEL.
Zinc, Sattu, TEL.		Antimony, Soorma, TEL.
Tin, Tagarum, TEL.		and HIND.

are the metals used in various proportions by native smiths to form brass. Gun metal, *lokam*, pewter *Satke*, bell metal, *kansu*, Biddery ware, and occasionally silver, is added to form gongs and bells. In general, however, the proportions used are regulated by reducing the proportions of the more expensive and increasing those of the cheaper metal as far as may be practicable. Repeated meltings by drawing off the excess of zinc leave a good malleable brass, and for this reason old brass is much sought after by smiths when they desire it for any work requiring it to be particularly malleable. They frequently use equal parts of zinc and copper, the proportion of zinc is necessarily much reduced by their mode of melting, still the product is a very inferior brass. Guns taken at Kurnool were little better than spelter.

The following proportions have been taken from C. Holtzapfel's remarks on copper alloys, the quantities shew the proportions to 1 lb. of copper;  $\frac{1}{2}$  to  $\frac{1}{2}$  oz. zinc is added to copper when used for castings, as pure copper generally does not cast sound: the usual mode is by adding 2 to 4 oz. brass to 1 lb. 6 oz. copper, brass that bears soldering well, Bristol brass is said to be of this proportion.

8 oz. ordinary brass less fit for soldering than 6 oz. being more fusible.

9 oz. to 16 oz. Muntz patent sheathing 40 zinc to 60 copper is the best proportion, it is cast in ingots, heated to a red heat, and at that heat rolled and forged for bolts &c.

12 oz. spelter for soldering iron pale yellow metal for dipping in acids is in this proportion. 16 oz.—soft spelter solder for ordinary brass work, 2 oz. copper to 1 lb. zinc a hard crystalline metal used for laps, polishing dishes &c.

The red color of copper slides into that of yellow brass at about 4 or 5 oz. to the lb. and remains little altered to 8 or 10 oz. after which it becomes whiter.

The alloys from 8 to 16 oz. are much used for furniture work, in all cases the metal is annealed

## BRASS.

before the application of the scouring or cleaning process.

The alloy of zinc and copper retain there malleability and ductility well to about 8 or 10 ounces to the pound, after this the crystalline character begins slowly to prevail.

The ordinary range of good yellow brass that files and turns well is from about  $4\frac{1}{2}$  to 9 oz. to the pound.

## ALLOYS WITH TIN.

- 1 oz. of tin to 1 lb. Copper—a soft gun metal.
- $1\frac{1}{2}$  „ harder, fit for wheels to be cut with teeth.
- $1\frac{1}{2}$  „ to 2 oz. Brass ordnance.
- 2 „ hard bearings for machinery.
- $2\frac{1}{2}$  „ very hard do
- 3 „ Soft musical bells.
- $3\frac{1}{2}$  „ Chinese gongs and cymbals.
- 4 „ house bells.
- $4\frac{1}{2}$  „ large bells.
- 5 „ largest bells.
- $7\frac{1}{4}$  „ to  $8\frac{1}{4}$  Speculum metal.

The tin alloy is scarcely malleable at 2 ounces, it soon becomes very hard, brittle and sonorous; alloys of  $1\frac{1}{4}$  cwt. to  $2\frac{1}{2}$  easily assume the maximum of hardness without being crystalline.

Native smiths render the mixed metal malleable with greater proportions of tin, so do the Chinese for their gongs and Cymbals by gently striking it while hot at repeated heatings: some years ago bronze sheathing for ships was prepared on the same principal. Natives call such malleable bell metal *akkansu* (Tel). Is is formed into vessels for containing acid food, buttermilk &c.

## WITH LEAD.

1 lb. of Copper to 2 oz. a red colored ductile alloy.

6 oz. common pot metal is brittle when warmed.

The alloy with lead chiefly used on account of the facility with which it can be turned or filed.

## WITH ZINC, TIN AND LEAD.

$1\frac{1}{2}$  oz. tin,  $\frac{1}{2}$  Zinc, 16 copper, Pumps and works requiring great tenacity.

$1\frac{1}{2}$  tin and 2 oz. brass to 16 Copper, Wheels to be cut into teeth.

2  $1\frac{1}{2}$  16 for turning work.

$2\frac{1}{4}$   $1\frac{1}{2}$  16 nuts of coarse threads and bearings.

Melt the copper alone, the brass in a separate crucible, the tin in a ladle, the two latter are added to the copper when it is removed from the furnace the whole are stirred together and poured into the moulds.

Ordinary yellow brass is rendered very sensibly harder by a small addition of tin say  $\frac{1}{2}$  or  $\frac{1}{4}$  oz. to the lb., on the other hand by the addition of a like quantity of lead it becomes more malleable and cuts sharply. Brass becomes a little whiter for the tin and redder for the lead, the addition of nickel to brass constitutes German silver.

Gun metal (copper and tin) by the addition of

a small proportion of zinc mixes better and the malleability is increased without materially reducing the hardness.—Lead in small quantities improves the ductility of the metal, but at the expence of its hardness and colour, it is seldom added.

Pot metal (copper and lead) is improved by the addition of tin and the three metals will mix in almost any proportions—Zinc may be added to Pot metal in very small quantity, but when the zinc becomes a considerable amount the copper takes up the zinc forming a kind of brass and leaves the lead at liberty, which in a great measure separate in cooling. Zinc and lead are indisposed to mix alone, though a little arsenic assists their union by “killing” the lead as in shot metal; antimony also facilitates the combination of pot metal,—7 lead 1 antimony and 16 copper mixed perfectly at the first fusion, and the mixture was harder than 4 lead and 16 copper and apparently a better metal.

This information is chiefly from Holtzapfel's mechanical manipulation a work which no person who attempts to improve native artificers should be without.—*Rohde, M.S.S.*

(474) *BRIDELIA MONTANA*: *CLUYTIA MONTANA*.

Patenga, TEL.

On the interior of mountains in the Circars this grows to be a tree, but on the lower lands it does not grow so large. The wood of this tree is very hard and of a reddish colour.—*Rohde, M.S.S.*

(475) *BRIDELIA SPINOSA*. *CLUYTIA SPINOSA*.

Koromana, TEL.

This is a tree of considerable size, a native of Circar mountains as well as of various parts of Bengal where it blossoms during the rainy season, chiefly in July, and the seeds ripen in December. The bark is a strong astringent. The wood dark coloured, hard and durable. Cattle eat the leaves greedily, they are said to destroy worms in their bowels, *Roxb.*—*Rohde, M.S.S.*

(476) BROTHER MAKING amongst the KYANS. The late Mr. Burns, thus related the ceremony. Singuding sent on board to request me to become his brother, according to Kyan fashion. The ceremony of becoming Singuding's brother he continues, came off to-day. It is called by the Kyans “berbiang,” by the Borneons “bersabibah.” I landed with our Nakodah, and after some preliminary talk, to allow the crowd to assemble, the affair commenced, we sat in the verandah of a long house, surrounded by some hundreds of men, women and children, all looking eagerly at the white stranger who was about to enter their tribe. Stripping my left arm, Kum Lia took a small piece of wood, shaped like a knife blade, and slightly piercing the skin brought blood to the surface, which

he carefully scraped off; then Nakodah Gadore drew blood in the same way from Singuding's right arm the one next me, and a small cigarette being produced, the blood on the wooden blades was spread on the tobacco, scarcely spread for the quantity was as small as could be imagined. A chief then rose, and walking to a sort of window, looked full upon the river, and invoked the spirits of good and evil to be witness of this tie of brotherhood; the cigarette was then lighted, and each of us took several puffs, and the ceremony was over.

The most remarkable ceremony is the one mentioned by Dalton, of the skewers; here they use copper, the bones of birds and monkeys, and hardwoods. The ceremony, I heard, took place after the birth of the first child, but from subsequent enquiries I find that is immediately after they have tunaged with a girl; that unless the lover submitted to it the girl would have nothing to say to him, that they measured the length of the skewers to be used by the length from the first to the second joint of the woman's third finger; that a great chief often used three, some two, others one, and that it never seemed to injure them in the slightest degree.—*Journ. Ind. Arch. Vol. V. No. XII.*

(477) *BUCHANANIA LATIFOLIA*.

Piyali, SANS, and BENG.	Charoo Mamidi, TEL.
Peeyar, Peeyal, Piyaloo,	Mowdo, or Kati Mango

*The Fruit.*

Chirika, SANS. | Chirongi, BENG.

A large tree, a native of the various parts of the coast. The wood of this tree is used for various purposes, and the kernels are a very general substitute for almonds.

From trial made of the quantity of oil that the kernel of the nuts of the *Buchanania latifolia* (Cherongy) would yield, there was obtained an English pint from two seers of seed.—*Rohde, M.S.S.*

(478) BUDIH. According to the Buddhist doctrine, matter is eternal, the existence of a world, its duration, destruction and reproduction, all the various combinations and modifications which matter is liable to, are the immediate result of the action of eternal and self existing laws.

The Trai Phum, a Buddhist work of Siam, is much venerated there. It is not an original work, received among the immense collection of canonical Buddhist books, called *Trai Bido* (in Burman *Bedegat*), but a compilation as we learn from the introduction to it, made in the Buddhist era 2326, (A. D. 1784, 67 years ago) when his Majesty, the great grandfather of the present king of Siam, in the presence of his nobles and retinue proposed a series of questions to the chief Hierarch, priests and learned men, some of which they were able to answer,

## BURNING AND KRISING.

and some they could not answer.—*Reed. J. T. Jones in Journal Indian Archipelago Vol. V. No. IX.*

(480) BUQR-EED, or Eed oos Zoha, held on the 9th day of the twelfth month Buqreed, on this occasion, Kings, princes, or Nabobs proceed to the Eed-gah in great state, when the khoot-bah is read in the name of the ruling sovereign.

(481) BURNING AND KRISING of Widows at the island of Lombok. On Lombok wives may suffer themselves to be burned after the death of their husbands. They are not compelled to do so. Such an event very seldom occurs, and during one traveller's stay there was only a single widow who allowed herself to be kried. They have the choice of allowing themselves to be burned, or kried. The first is the more rare. The wives of the Rajas, however, must suffer themselves to be burned. When a Raja dies some women are always burned, even should they be but slaves. The wives of the priests never kill themselves. Having been present at one of these horrid spectacles I shall, he adds, relate how it was conducted.

The gusti who died at Ampanan left three wives. One of them resolved to let herself be kried in honor of him, and that against the will of all on both sides of her family. The woman was still young and beautiful; she had no children. They told me that a woman who under such circumstances, suffered herself to be killed had indeed loved her husband. She intended to accompany him on his long journey to the gods, and she hoped to be his favorite in the other world.

The day after the death of the gusti, his wife took many baths; she was clothed in the richest manner; she passed the day with relatives and friends, drinking, chewing sirih and praying. About the middle of the space before the house they had erected two scaffoldings or platforms of bambu of the length of a man, and three feet above the ground. Under these they had dug a small pit to receive the water and the blood that should flow. In a small house at one side and opposite these frame works were two others entirely similar. This house was immediately behind the *bali-bali*.

At four o'clock in the afternoon men brought out the body of the gusti wrapped in fine linen, and placed it on the left of the two central platforms. A priest of Mataram removed the cloth from the body while young persons hastened to cover the private parts of the dead with their hands. They threw much water over the corpse, washed it, combed the hair, and covered the whole body with *châmpakâ* and *Kânangâ* flowers. They then brought a white net. The priest took a silver cup filled with holy water (called *chor*) on which he strewed flowers. He first sprink-

## BURNING AND KRISING.

led the deceased with this water, and then poured it through the net on the body, which he blessed, praying, singing, and making various mystical and symbolical motions. He afterwards powdered the body with flour of coloured rice and chopped flowers, and placed it on dry mats.

Women brought out the wife of the gusti on their crossed arms. She was clothed with a piece of white linen only. Her hair was crowned with flowers of the *Chrysanthemum Indicum*. She was quiet, and betrayed neither fear nor regret. She placed herself standing before the body of her husband, raised her arms on high, and made a prayer in silence. Women approached her and presented to her small bouquets of *kembang spatu*, and other flowers. She took them one by one and placed them between the fingers of her hands raised above her head. On this the women took them away and dried them. On receiving and giving back each bouquet the wife of the gusti turned a little to the right, so that when she had received the whole she had turned quite round. She prayed anew in silence, went to the corpse of her husband, kissed it on the head, the breast, below the navel, the knees, the feet, and returned to her place. They took off her rings. She crossed her arms on her breast. Two women took her by the arms. Her brother (this time a brother by adoption) placed himself before her, and asked her with a soft voice if she was determined to die, and when she gave a sign of assent with her head, he asked her forgiveness for being obliged to kill her. At once he seized his kris and stabbed her on the left side of the breast, but not very deeply, so that she remained standing. He then threw his kris down and ran off. A man of consideration approached her, and buried his kris to the hilt in the breast of the unfortunate woman, who sunk down at once without a cry. The women placed her on a mat, and sought, by rolling and pressure, to cause the blood to flow as quickly as possible. The victim being not yet dead, she was stabbed again with a kris between the shoulders. They then laid her on the second platform near her husband. The same ceremonies that had taken place for him now began for the wife. When all was ended, both bodies were covered with resin and cosmetic stuffs, enveloped in white linen, and placed in the small side house on the platforms. There they remain until the time arrives for their being burned together.

It is always a near relation who gives the first wound with the kris, but never father or son. Sometimes dreadful spectacles occur; such was one at which Mr. K. was present. The woman had received eight kris stabs, and was yet quite sensible. At last she screamed out, impelled by the dreadful pain, "Cruel wretches, are you not able to give me a stab that will kill

me?" A gusti who stood behind her, on this pierced her through and through with his kris.

The native spectators, whom I had around me, saw in this slaughter which took place before our eyes, nothing shocking. They laughed and talked as if it was nothing. The man who had given the three last stabs wiped his kris, and restored it to its place, in as cold blooded a manner as a butcher would have done after slaughtering an animal.

Only the wives of the more considerable personages of the land allow themselves to be burned, because this is attended with much more expence than krising. They then make a very high platform of bambu. The woman ascends after many ceremonies, and when the fire is at its greatest heat. She then springs from above into the middle of the flames. Mr. K. thinks that they do not suffer much because during the leap they are stifled; and at all events the fire, strengthened by fragrant resins, is so fierce that death must speedily ensue.

The Balinese dress on Lombok in the same manner as on Bali, and the Sassaks nearly in the same way. For example, although Mahomedans, they have uncovered heads. The Sassak women differ a little in their dress from the Balinese. In the first place they do not bind up their hair with a piece of white cloth, like the Balinese, but go bareheaded like the men. Some wear a short *baju* like the women of Sambawa and Makassar, others have the bosom naked, or covered with a *slendang* of a coarse stuff, striped red and black in the length. The *sarung* is almost always of blue or black cloth.

The food of the people of Lombok differs in nothing from that of the people of Java. The Balinese, who may not eat beef, substitute for it pork. Both races eat buffalo flesh, goat's flesh, fish and poultry.

The people of Lombok are neither more nor less superstitious, than all the other people of the Archipelago. It is the Rinjani especially which makes an impression on the people, on account of the bad spirits which reside upon it. My travelling companions for example, he adds, told me not to shout upon the mountain because the bad spirits would become irritated, and not to take any stones from the ground, because they would resent it and play us some bad trick. Whoever wishes to approach the Segara Anak must be blessed, fasting, and have said his prayers and be clothed in white. As they approach it they must notice what appearance it presents to them. The more lengthened it appears to them, the longer time will they live. If it looms broad, they will quickly die. All these ideas are found however over all the Archipelago, round the great volcanoes, and in spite of all modifications which they have undergone, through time or local circumstances, they are all

based upon the belief of a supernatural and malevolent power which causes and regulates, the working of the subterranean fire. No religion, not even the Christian, will root out these fixed ideas from this people. Impressive phenomena, like volcanic, sound louder than all reasonings in the ears of uncivilized and timid men.—*Journ. Ind. Arch. No. IX. Vol. V. p. 537.*

Palas, SANS.

Palas, BENG.

Moodooga, TEL.

Plasa, RHEED.

Not very common on the low land of the coast, but much more so among the mountains and still more in Bengah. Leaves deciduous, during the cold season, they come out again with the flowers, about the months of March and April, seed ripe in June and July.

From natural fissures, and, from wounds made in the bark during the hot season, there issues a most beautiful red juice which soon hardens into a ruby coloured, brittle astringent gum, but it soon loses its beautiful colour if exposed to the air. The dried flowers are called "*Tesoo*."

Infusions of the flowers either fresh or dried dye cotton cloth previously impregnated with a solution of alum, or alum and tartar, of a most beautiful bright yellow which is more or less deep according to the strength of the infusion. A little alkali added to the infusion, changes it to a deep reddish orange. It then dyes unprepared cotton cloth of the same colour, which the least acid changes to a yellow or lemon. These beautiful colours Mr. Rohde had not been able to render perfectly permanent. The lac insects are frequently found on the small branches and on the petioles of the leaves of this tree. The natives are not known to make any use of the gum or flowers, although they promise to be valuable. The former is a medicine, and the latter as a pigment, and dyeing drug.—*Rohde, M.S.S.*

(486) BUTTER MILK.

Moroo, TAM.

## CALOTES.

### (488) CAESALPINIA SAPPAN.

Teng-yet, or Ten-yet, BURM.

This grows abundantly in the province of Mergui, and adjacent parts of Siam, in several parts of the Shyān territory, and among the mountainous regions of Manipore. The full grown tree is seldom higher than from fourteen to sixteen feet; thorny, bearing a large yellow flower in the month of August; leaves, small and of a dark green. It belongs to the same order of plants with *Brazil wood*.—*Malcolm's Travels*.

(489) CAESALPINIA SEPIARIA is much used in the Bombay Deccan as a fence. Hyder Ali surrounded fortified places with it.—*Chow-Chow*, p. 300.

(490) CAJEPUT is a corruption of the Malay words kaya-putih, literally "white wood" from the colour of the bark of the tree and which produces the well-known essential oil, the *Melaleuca cajeput* of botanists. It most abounds in the island of Borneo in the Molucca Sea, where the essential oil is obtained by the distillation of the leaves.—*Crowford Dicty.* page 79.

(491) CAJO MARM, is the Malayala name for the Cashew-nut tree. This tree grows to about ten inches diameter, and covers a large surface. It is considered the best sort of wood for charcoal, and is felled for this purpose only. With this as a substitute for coals, the assistance of a sheep-skin for bellows, and a hole in the ground for a forge, the native smiths produce any piece of iron-work that may be required for ship-work; iron knees and channel-work for large vessels; and the brass foundry, any piece of metal, such as the pintles and braces for ships of 700 tons burden.—*Edge M. and C.*

(492) CALLICARPA LANATA (Roxb.) bitterish, and rather aromatic.—*O' Sh.* p. 486.

(493) CALAMUS AROMATICUS. ANDROPOGON CALAMUS AROMATICUS. The sweet flag is used in Chinese medicine to a great extent for its spicy warmth.—*William's Middle Kingdom*, p. 278.

(494) CALOTES. T. C. Jerdon, Esq. sent from Saugur, a bottle of reptiles comprising one remarkable new species, which may be described as a Calotes, with enormous head, short and thick body, the tail not exceeding the body in length, and the toes also short and strong; a slight nuchal crest, and medial dorsal ridge composed of a row of high keeled scales; two detached tufts of sincipital spines, one contiguous to the tympanum, and each comprising one principal spine. Colour olive with a row of large round dark spots, bordered and set off with white

## CANARIUM COMMUNE.

along the back and anterior half of the tail, then continued as simple indistinct dark spots to the end of the tail, the white broader and forming a kind of pale spot on each side of the neck; and anterior to this first large spot is a smaller one upon the crest: lower parts yellowish-white, the throat regularly speckled with pale dusky: a conspicuous oblique white band passing from beneath the eye to the angle of the mouth, scales of the body in transverse bands, the oblique tendency much less conspicuous than in Calotes.—*Jour. of the Asia. Soc. of Beng.* No. ii. 1856, page 448.

### (495) CALOPHILLUM INOPHILLUM.

Ponna maram, RHEED.	Alexandrian laurel,
Ponna, TEL.	ENG.
Saltaha Champa, HIND.	

This most elegant tree is to be found in a cultivated state over most parts of India and indigenous near the shores of the southern parts. It is in flower and fruit most part of the year and is particularly beautiful. The wood is believed to be used for knees of ships.—*Rohde, M.S.E.*

(496) CAMELS. An instance of great endurance of the Camel is mentioned by Captain Smith, who purchased one, named Tippoo Sahib, for three hundred Rupees, that carried him six hundred and eighty miles in 12 days across the desert of India from Joudpore to Sukkur in Sind. On another occasion the same camel carried him 110 miles from Sukkur to Kotree without a halt, in thirty hours.—*Smith's 5 years at Nepal*, p. 20 and 26.

(497) CANARIUM. Under the head of "*Canarium*," Wight observes.—The resinous juice of the *Canarium commune* has properties similar to Copaiva, while on the other hand the kernels of the seed afford by expression a bland edible oil. The *Canarium strictum* of Roxburgh is known in Malabar under the name of the "black dammer tree" in contradistinction to the *Vateria* which is the "white dammer tree." This tree is rather common in the Alpine forests about Courtallum in the Tinnevely district, and is there regularly rented for the sake of its dammer. The dammer is transparent and of a deep brownish yellow or amber color when held between the eye and the light but when adhering to the tree has a bright shining black appearance. The flowers of the species had not been seen, the fruit is a very hard three celled oval nut tapering at each end.—*Wight Ill.*

(498) CANARIUM COMMUNE. (Roxb. *Fl. Ind. Vol. iii. p. 137.*) A native of the continent of India, the Archipelago and Isle of

## CANIS.

France, where it is called "Bois de Coloquane." It was brought from the Moluccas to the Calcutta Botanic garden, but in Roxburgh's time did not thrive, owing to the coldness of the winter months. The bark yields an abundance of limpid oil with a pungent turpentine smell, congealing into a buttery camphoraceous mass.

(499) CANAVALIA, with long straightish compressed pods, having three short wings at the lower suture, cellular dissepiments, and oblong seeds with a narrow hilum, comprehends the South American Lima Beans and the Sword Beans of India. The species have a handsomer and firmer foliage than the other genera, and the flowers are usually large and showy.

(500) CANAVALIA GLADIATA, the common cultivated species, has often pods two feet long, and varies with red, gray, and white seeds.

(501) CANAVALIA OBTUSIFOLIA D. C.

Koyli avaree, TAM.

Common on the sea-shore, frequently entwined with the last named binder, is also a very useful plant, and is very abundant at the Pdyar, Ennore, the mouth of the Godavery, and between Quilon and Anjengo.—*Cleghorn*.

(502) CANDLE-TREE. The nuts of the candle-nut tree (*Aleurites triloba*) are strung together and used for candles. Species of torches are also made from the candle wood in Demerara.

(503) CANDLES may be appropriately mentioned here, though the mode of making them is probably not Indian, but taught by Europeans. The natives use oil lamps, of various shapes, often of metal fixed on an iron spike, which they stick into the ground. But candles are now made in India; as, for instance, the wax candles from Patna, and the stearic candles of the Messrs. Sainte from Calcutta.—*Royle Arts &c. of India*, page 484.

(504) CANDY, A measure of weight equal to 500 lbs.

(505) CANJARA, the Tamil and Malayala name of a tree which grows to about two feet and a half in diameter, and from twenty-five to thirty high of little use or durability. The natives value its fruit, which is very intoxicating, and used by them as a medicine.—*Edge. M and C*.

(506) CANIS. Arthur Grote, Esq. B. C. S. lately sent the skins and skeletons of a mature female and male  $\frac{1}{3}$  grown of the ordinary Wild Dog (so called) of this country from Chaibasa in Central India. These animals were specifically identical with a particularly fine living adult male in Mr. Bligh's own possession sent down from Upper Assam, and this appears to be the ordinary species alike of the Himalaya and of Central and S. India *Canis Dukhunensis* Sykes and *C. primævus* Hodgson, and a Malayan specimen in the Calcutta Museum which he takes to be *C. sumatrensis*. Hardwicke would appear to differ only in the considerably deeper tint of its

## CARYOTA URENS.

rufous colouring.—*Journal of the Asiatic Society of Bengal*, p. 440.

(507) CAPPARIS TRIFOLIATA. THREE-LEAVED CAPER: CRATÆVA ROXBURGHII. The three-leaved caper tree produces large handsome terminal heads of flowers with numerous purple stamens and white clawed petals that change to cream color.

(508) CARABUS CŒLESTIS. Not the least striking of the beetles obtained in China was this beautiful species of Carabus.—*A Res. among the Chi*. p. 62.

(509) CARAWAY, Black. Zeera seeah. Fruits of Carum Nigrum, a good substitute for Carum Carui, the seed of the Somraj (*Conyza anthelmintica*), are often sold for it in the bazar; about  $\frac{1}{8}$  of an inch long, slightly winged, flat, ovato-lanceolate, ribbed on one surface.

(510) CARBUNCLE.

Manikiam, TEL. and TAM.—*Rhode, M.S.S.*

(511) CARDAMOMS. Yalakki (Can) Cardamom (Eng) Cardamoms are extensively grown in the woods north of Nuggur; and are exported to all parts of Southern India.—*M. E. J. R.*

Cardamoms are known in the Malay and Javanese languages by two names, kapulaga and puwar, which have every appearance of being native words, and yet the plant is neither indigenous nor cultivated in the Indian islands. It is the exclusive product of three countries only, Malabar, Ceylon, and Kamboja, and in these the spontaneous product of the forest incapable of cultivation. An immemorial commercial intercourse has existed between these and the Malayan countries.—*Crawford Dictionary*, page 83.

(512) CARBONATE OF SODA. Impure Carbonate of Soda; Dhobies earth?

(513) CAREYA ARBOREA. Koomblee is the name of its fibre employed in the Himalayas as slow match for the matchlocks.

(514) CARYOTA URENS. Lin. BEAD-SEED KOONDEL PANEL.

*The Seed.*

Koondel Panai Munnie, TAM.

The dark coloured, oval seeds of the Caryota urens are used by the Mahomedans as beads. The tree is called Erimpanna in Canarese.—*Ainslie's Mat. Med.* p. 142.

*The Tree.*

Kamboo kara, TEL.	Pooti tanni maram, TAM.
Pelon, RHEED.	Erimpanna, CAN.

A tree of immense size growing on the mountains of Coromandel &c. where it blossoms during the hot season, the seed ripens about three or four months after.

The wood is used for furniture and for many purposes where it is not exposed to the weather. It is light and of light yellow colour; it is very liable to twist and warp, another timber Bandaroo

# CASSIA LIGNEA.

is confounded with this in name on the Godavery.—*Rohde, M.S.S.*

(515) CARROO MARRATHIOO. *Terminalia elata*, used for the same purposes as Ben Teak under which name it is frequently sold. Common on the Western Ghats and in Wynaad, the wood is not durable.—*Hg. McIner, M. E.*

(516) CARISSA CARANDAS: its berries make good tarts, and the plant itself forms tolerable hedges.—*Hooker Him Jour., page 13.*

(517) CARPETS. The Indian carpets most commonly met with are of cotton, in blue, red, and white; and although durable, possessing no other good quality. Some few made of cotton and silk for great potentates are extremely beautiful.

# (518) CARYOTA URENS.

Teerooga, TEL. | Schundapana, RHEED.

A native of the various mountainous parts of India, where it grows to be one of the largest and most charming of this beautiful tribe or natural order. Flowering time the hot and rainy seasons. This tree is highly valuable to the natives of the countries where it grows plentifully. It yields to them during the hot season an immense quantity of toddy or palm wine. The best trees it is said will yield at the rate of one hundred pints in the twenty-four hours. The pitti or farinaceous part of the trunk of old trees is said to be equal to the best sago, the natives make it into bread, and boil it into thick gruel, these form a great part of the diet of the people and during a late famine in India they suffered little while these trees lasted. This substance is highly nutritious. The gruel is fully as palatable as that made of sago from the Malay countries *Roxb.--Rohde, M.S.S.*

The Native practitioners of India, consider this to be a valuable laxative; and prescribe it in the form of electuary in cases of habitual costiveness; the flower of the plant is also employed in decoction for wind and pain in the stomach.—*Ainslie's Materia Med. p. 8.*

# (520) CASSIA LIGNEA.

Lawunga puttay, TAM.	Twacha, SANS.
Darchinie, DUK.	Cayoomanis, MALAY.
Tej, HIND.	Laurus cassia, LIN.
Seleekheh, ARAB.	

This is a favorite medicine of the Mahomedan, as well as the Tamool practitioners, who consider it as a grateful and useful stomachic. Great part of that used in India comes from the coast of Borneo, or from Ceylon, where it is called

# CASUARINA MURICATA.

Dawul Curundu. It is however, a natural product of India, and is found growing in abundance in the woods of Canara and Malabar, in which first mentioned country it has got the name of Ticay. Its Hindoostanee appellation is Tejpat, in Sanscrit it is Tamala patra.—*Ainslie's Materia Med. p. 8.*

(521) CASSOWARY. *Casuarus* or *Bennettii* of Gould. *New species.* Moorook, in the language of New Britain. Dr. Bennet, in a letter dated Sydney 10th Sept. 1857, says, a new species of Cassuary was recently brought to Sydney, procured from the natives of New Britain an island near to new Guinea. The height of the bird is three feet to the top of the back, and five feet when standing erect. Its colour is rufous, mixed with black on the back and hinder portions of the body, and raven black about the neck and breast. The loose wavy skin of the neck is beautifully colored with iridescent tints of blueish purple, pink and an occasional shady green, quite different from the red and purple caruncles of the *Casuarus galeatus*. The feet and legs which are very large and strong are of a pale ash colour. This bird also differs from the *C. galeatus* in having a horny plate, instead of a helmet like protuberance on the top of the head: which callous plate has the character of and resembles mother of pearl darkened with black-lead. The form of the bill differs considerably from that of the Emu *Dromaius Novæ Hollandiæ* being narrower, larger, and more curved, and in having a black or leathery case at the base. Behind the plate of the head is a small tuft of black hair like feathers, which are continued in greater or lesser abundance over most parts of the neck. The egg is about the same size as that of the Emu, and is of a dirty pale yellowish green colour. The bird appears to Dr. Bennet, to approximate more nearly to the Emu than to the Cassowary, and to form the link between these species. In its bearing and style of walking it resembles the former, throwing the head forward, and only becoming perfectly erect when running; It also very much resembles the *Apteryx* in its body, in the style of the motion and in its attitudes. Its bill presents a great deal the character of that of a rail: it utters a peculiar, chirping whistling sound, but also a loud one resembling that of the word "Mooruk," whence, no doubt, it derived its native name.

Of the particular section of the *Struthionidæ* there are now three species, *C. galeatus*, a native of N. Guinea; *C. Australia* inhabiting the Cape York district of Australis: and *C. Bennettii*, whose domicile is New Britain—*London Athenæum, No. 1512, December 12, 1857. p. 1551.*

# (522) CASUARINA MURICATA.

Surva Chettoo, TEL.

This is said to be a native of the sand hills on

the sea side in the province of Chittagong and from thence was sent by Dr. Buchanan to the Botanic garden of Calcutta, where in the course of 10 years from the seed, they grew to be trees of from sixty to eighty feet in height with trunks three feet and a half in circumference, four feet above ground, but in their native soil, the large trees are said to be nearly one hundred feet high and nine or ten feet in circumference. The wood is not held in estimation though of a reddish colour, and texture like *Cedrela Toona*. In the Botanic garden they blossomed during the months of February and March.—*Rox.*

The cones must be collected before they burst, and by placing them in a pot in a dry and warm place, the seed will be found shed from them in a few days: it should be sown immediately.—*Rohde, M. S. S.*

### (523) CATGUT, CATLING.

*Rhoda, Guz. Hind.*

A kind of rope somewhat resembling Catgut is made by the chucklers of the sinews of animals, it answers tolerably for lathe bands, drill bow strings &c. As there is good reason to believe that Catgut of superior quality might be prepared in this country, and the process is simple, Mr. Rohde gives the description of the manufacture.

The guts being taken while warm out of the body of the animal are to be cleared of feculent matter, freed from any adhering fat and washed in a tub of water. The small ends of all the intestines are next to be tied together and laid on the edge of the tub, while the body of them is left to steep in some water, frequently changed, during two days, in order to loosen the peritoneal and mucous membranes. The bundle of intestine is then laid upon a sloping table, which everhangs the tub and their surface is scraped with the back of a knife, to try if the external membrane will come away freely in breadths of about half the circumference. This substance is called by the French Manufacturers *filandre*, and the process *fibre*. If we attempt to remove it by beginning at the large end of the intestine we shall not succeed. This *filandre* is employed as thread to sew intestines and to make the cords of rackets and bottledores. The flayed guts are put again into fresh water, and after steeping a night, are taken out and scraped clean next day, on the wooden bench with the roundest back of a knife.

This is called curing the gut. The large ends are now cut off, and sold to the pork butchers. The intestines are again steeped for a night in fresh water, and the following day in an alkaline lixivium made by adding 4 ounces of potash and as much pearlsh, to a pail of water containing about 3 or 4 imperial gallons. The lye is poured in successive quantities upon the intestines, and poured off again after 2 or 3 hours, till they be purified. They are now drawn several times

through an open brass thimble, and pressed again it with the nail, in order to smooth and equalize their surface. They are lastly sorted according to their sizes to suit different purposes. Whip-cord is made from the above intestines, which are sewed together endwise by the *filandre*, each junction being cut a slant so as to make it strong and smooth. The cord is put into the frame, and each end is twisted separately, for whip-cord is seldom made out of two guts twisted together. When twisted it is to be sulphured once or twice. It may also be dyed black with common ink, pink with red ink which the sulphurous acid changes to pink, and given with a green dye which the colour dealers sell for the purpose. The guts take the dyes readily after being well smoothed, the cord is to be dried and coiled up for sale.

*Hatters cords for bow strings.*—The longest and largest intestines of sheep, after being properly treated with the potash are to be twisted 4, 6, 8, 10 or 12 together according to the intended size of the cord, which is usually made from 15 to 25 feet long. This cord must be free from seams and knots when half dry, it must be exposed twice to the fumes of burning sulphur and after each operation, it is to be well stretched and smoothed; it should be finally dried in a state of tension.

*Clock makers Cord*—This cord should be extremely thin, and be therefore made of very small intestines, or from intestines slit up in their length by a knife fitted for the purpose being a kind of lancet surmounted with a ball of lead or wood. The wet gut is strained over the ball which guides the knife, and the two sections fall down into a vessel placed beneath. Each hand pulls a section. Clock makers also make use of stronger cords made of 2 or more guts twisted together.

*Fiddle and harp strings*—These require the greatest care and dexterity on the part of the workmen—The treble strings are peculiarly difficult to make, and are best made at Naples, probably because their sheep, from their small size and leanness, afford the best raw material.

The first scraping of the guts intended for fiddle strings must be very carefully performed and the alkaline lyes being clarified with a little alum, are added in progressively stronger state from day to day, during 4 or 5 days, till the guts be well bleached and swollen. They must then be passed through the thimble and again cleansed with the lixivium, after which they are washed; spun, or twisted and sulphured during two hours. They are finally polished by friction and dried: sometimes they are sulphured twice or thrice before being dried and are polished between horse hair cords.

It is well known to physiologists that the membranes of lean animals are far more tough than of those animals which are fat or in

## CELEBES.

high condition, and there is no reason to doubt that the superiority of the Italian strings arises from the state of the sheep in that country.

For preserving lathe bands the juice of garlic is a good application.—*Rohde, M.S.S.*

### (524) CATECHU.

Kachu, MALAY; Shah, BURM.

The *Acacia* or *Mimos* Catechu, is indigenous, in Burmah rising sometimes to a height of forty feet. Timber, tough and durable, much used for ploughs, and from this tree is made the catechu, cutch, or terr japonica, chewed generally with the betel-nut. The wood is hewed into chips, boiled and the liquor inspissated till it becomes thick enough to spread on a mat, when the drying is completed in the sun. It dissolves completely in water, is slightly bitter, highly astringent, and contains fifty-five parts in a hundred of tannin. Burmans make two kinds, the red and the black; both from the same tree. The red is preferred in Bengal, and the black in China. It is chiefly made in the neighbourhood of Prome, though the tree is found in all parts of the country.—*Malcolm's Travels in South Eastern Asia, Vol. 1. p. 187.*

A similar article is produced in Malaya, from the plant called *Uncaria gambier* and in Egypt and Arabia from the *Acacia*. It has lately been exported from Singapore to England in large quantities, for tanning.

### (525) CAZEE, a Mahomedan Judge.

### (526) CELASTRUS MONTANA.

Peddo, TEL.

A small tree, a native of the Circar mountains. The wood of this tree is hard and durable.—*Rox.*  
—*Rohde, M.S.S.*

### (527) CELASTRUS PANICULATA.

*The oil.*

Malkungunee or staff Tree oil—*Celastrus paniculata*. Oleum Nigrum—*Valulavy tylum*.

Valulavy yennai, TAM. | Malkungunee ka tael HD.  
Bavungie noona, TEL. | Vaylarie tylum, TAM.

An empyreumatic oil obtained by the destructive distillation of the seeds of the *Celastrus*, either alone or in combination with other ingredients. It was much used in the treatment of Beri-beri, *Macolmson's Essay, p. 312.—M.E. J.R.*

(528) CELEBES. The tongue of land in the north of Celebes, known administratively under the name of the residency of Menado, comprehends all the northern extent of the island, from the bay of Palos in the west, to the cape of Taliabo in the east, and comprises the great bay or arm of the sea of Gunong-tello, which stretches in a westerly direction between the two peninsulas. The residency of Menado includes under its jurisdiction, the whole federative states of

## CELEBES.

Minahassa; the small kingdoms of the northern coast; the very extensive districts in the west part of the peninsula, where government exercise sway, besides the islands of Sangir and Talau to the north, as well as the lesser islands of the west coast and the large gulf of Tomini.

The population is composed of Native Christians, Malays and Chinese. In 1440 there were reckoned in Minahassa:—

Natives.	-	-	73,700
Christians.	-	-	5,687
Malays.	-	-	2,875
Chinese.	-	-	510
Freed Slaves.	-	-	500

----- 88,272

The districts of Gorontalo. - 50,000

Sangir and Talaut islands. - 40,000

-----  
Total...178,272

Without taking into account the number of the Alfouira population of the interior, which cannot be very considerable, seeing that the elevated and woody parts of Kayeli, Toradja and Tomeiku appear to be thinly peopled.

The Minahassa confederation counts 286 villages; the principal districts are Tondano, Langgong, Kakes, Temehon, Sonder, Kawakkoang, Tompasse, Amurang, Belang and Kema. They are all under the direct authority of Government; the resident and three other European civil employes, assisted by an indeterminate number of native functionaries, administer the government. The resident is under the orders of the governor of the Moluccas, the head quarters of which is Amboyna.

Sangir and the numerous islands of this group occupy a superficies of 13 square leagues, the Tolaut and the Meangis islands united are 18 square leagues; these archipelagoes, formerly subject to the authority of the Sultans of Ternate, now make part of the residency of Menado.

Several extinct volcanoes, and some still in full action, are found in the Sangir group; the devastations which they commit from time to time, have often been fatal to the inhabitants. The eruption of Dawana, in 1808, completely annihilated the village of Tagalando, destroyed all the surrounding forests, and suddenly deprived the inhabitants of all means of livelihood, by the destruction of their fields. The Gunong-api causes numerous ravages in the island of Sjauw; its peak, 6000 feet above the level of the sea, forms the culminating point of this group. Gunong abu covers with its base all the northern part of Sangir-besar, this volcano has not been acted since 1812 when the torrents of lava destroyed the extensive forests of coconut trees with which this part of the island was covered, and caused the death of many of the inhabitants. These islands furnish more than twenty-five kinds of wood suited for building and furniture. Two har-

## GERAMIC MANUFACTURES.

bours, sheltered from all winds, exist in the larger Sangir; one in the Bay of Taruna, the other, called Midelu, on the eastern side.—*Journ. Ind. Arch. for Dec. 1850, page 764.*

(529) **GERAMIC MANUFACTURES, CHINA PORCELAIN, EARTHENWARE, &c.** This art may still be said to be in its infancy in India as no great perfection has been attained in any branch.

*Earthenware or Common Pottery.*—There are three distinct branches of this manufacture which though similar in their manipulation are different in their results. The most common kind is the red porous earthenware used for chatties and cooking vessels, the black used for similar purposes and the fine white which resembles some of the biscuit earthenware of Europe.

The red porous earthenware differs very materially in quality according to the locality from which the clay is selected—some are made of a common coarse earthy loam which has very little tenacity, and yields a brittle kind of pottery neither susceptible of much finish nor of being glazed. Most of the Pottery of India is of this description, it is made on a curious principle which is unknown in other countries but which has probably been followed for many centuries in India. The vessels which are mostly of a round form are thrown thick in the neck and upper parts or sides. They are cut off the wheel and left open in the bottom with vertical sides, they are then allowed to harden a little in the necks and as soon as they will bear to be handled the sides are thinned out by beating with a flat mallet upon a rounded stone or very hard round piece of wood held inside the vessel which is turned about and beaten till it is closed. This is a very tedious and unsatisfactory mode of working and the only recommendation is, that it makes a thin-walled vessel but at a great sacrifice of time; from 10 to 20 of these is a good day's work, while a skilful European thrower will turn out 500 in the same time. Good samples of this quality of earthenware were exhibited from Travancore, at the Madras Exhibition, they are made from a fine smooth Micaceous loam and the general forms are good though heavy. A finer description of this ware was exhibited from Hyderabad, made from a tough smooth plastic clay and the articles were remarkable for elegance of form and extreme lightness of throwing. Some of the vessels had been ornamented with gold leaf and coloured lac varnishes; others had been made in imitation of Bederie ware, some were painted white on a red ground; a few appeared to have been glazed and coloured with a soft lead glaze—On the whole this collection exhibited a marked improvement on the ordinary manufactures of this class; tasteful forms and light throwing being combined and a good effect having been produced with simple means.

## GERAMIC MANUFACTURES.

The following Remarks by Captain Ivie Campbell, Offg. Deputy Commissioner, E. Du. R. Doab, Raichore, 28th August, 1855, upon the Pottery from Raichore sent to the Madras Exhibition, will be read with interest. "There is but one family in Raichore which can make this description of pottery, they are christians long established here and the party to whom the amount of prize has been paid was by Rajah Chundu Lall presented (probably on account of his skill) with a small ruined hamlet in Mukta, and which has been continued to him by order of the Resident. A brother of his resides at the Beebee Chushma at the city, but the same quality of clay is not procurable there, and his work is stated to be inferior; much of what he sells in the city, gilt chillums &c., he receives from his brother here.

How far his account of the composition of the glaze used can be depended on I cannot say, he states that no lac is used except in fixing the gold leaf, the following is the account given by him.

24 parts Moordar Sing or Litharge.

3 do. Gar ke Puttur, a stone resembling white quartz common here.

1 part Copper.

Sendoor or the red oxide of lead may be substituted for the Litharge.

The Gar ke puttur, should be well burnt, slaked in cold water and afterwards reduced to a fine powder and mixed with the Litharge. The copper is mixed with its weight of finely powdered sulphur and heated in a crucible till a green scale has formed on it, it is then finely powdered and mixed with the Gar ke puttur and Litharge. The whole is again heated and reduced to a fine powder once more.

A small quantity of this powder is well mixed with wheat starch and kneaded well for some time, water is then added and it is strained through a fine cloth, and the glaze is gently rubbed in with the hand, after which the pottery is baked."

This process of glazing pottery is very similar to that practised in Italy, Germany and some parts of England where paving tiles, green flower pots and common red Earthenware, are manufactured. The Gar ke puttur is probably either white Felspar or Pegmatite a variety of granite very abundant in Southern India and composed of 3 parts Felspar and about 1 part of quartz. The clay which is employed is probably more refractory than the common red clays of India, most of which begin to lose their shape or to become spongy at the temperature for melting such glazes. The above details are of considerable interest as they prove that the art of pottery is improving in Southern India.

*Antique pottery*—The finest specimens of common earthenware are the ancient funereal, dome,

tic and cooking vessels, dug out of the old Tombs in the districts of Coimbatore and South Arcot. This kind of pottery has been found in many parts of India in tombs usually arranged in circles, each tomb being built of 6 slabs of stone and occasionally surmounted by large mounds of loose stones and earth. They have been thought to resemble the Druidical tombs of England, and are supposed to be of great antiquity, there being no records of them extant.

The pottery usually consists of tall narrow cinerary urns of 18 or 20 inches in length, with three or four clumsy feet, 4 inches in length, and of a variety of round oval and flattened vessels of different shapes and sizes, some having apparently been used for cooking and others as drinking vessels. The tall urns usually contain burnt human bones, teeth and ornament of brass, or copper, they are made of a coarse clay, and have not been finished with care, some of the flattened oval and rounded vessels are made of a fine dense clay that has been carefully prepared, the surfaces are variously ornamented with wavy or crossed lines of red and yellow carefully painted. The pottery appears also to have been smeared (it resembles the potteric antique vernissee et lustree figured by M. Brongniart.) There is great purity of form in most of the vessels which resemble the Etruscan in the precision of the curves and in the angles at which the different surfaces meet. The art of pottery appears to have deteriorated in India, since these samples were made and one branch of it is apparently lost viz., the smearing or thin glazing on the surface.

**Black Earthenware.**—This is a mere variety of the Red and in most instances it is the same kind of Pottery blackened by the simple process of damping or checking the fire when it is beginning to decline, and thus throwing a great deal of smoke amongst the wares when the heat is not sufficiently intense to burn it off. A better and stronger kind of black Earthenware is manufactured at Bangalore from a fine dense clay that contains both manganese and iron. This approaches the black stoneware of Egypt, and is strong and sonorous when struck; some good samples were also exhibited in the collection of colored Terra Cottas from the Madras School of Arts.

**White Earthenware.**—Some light and elegant samples of goglets, butter pots and vases, were exhibited by the Arcot Local Committee. These were considered deserving of a 2d Class Medal. This branch of the Art differs from the others in being conducted with more care and cleanliness, some attention being paid to the sifting of the materials and to the ornamenting and finishing of the articles. The material selected is a decaying white granite resembling the cornish stone of England or the graun of Germany.

This is carefully washed, and decanted to free it from sand or impurities; it is then allowed to subside, the water is poured off and the soft clay is collected on a clean cloth and laid on a heap of white wood ashes to dry; a small percentage of alkali is thus absorbed through the cloth and is incorporated through the mass by kneading. This clay or decayed white granite is the true kaolin or Porcelain earth of China and Europe. It is particularly abundant in India and occurs in beds of enormous extent and of every variety of color. It possesses the valuable qualities of combining with a large percentage of Silica, Felspar, Baryta or other stony bodies and of resisting the most intense heats, but in India it is employed alone and produces a soft brittle porous ware which is not susceptible of being well glazed. Numerous attempts have been made to glaze this description of Pottery but the glaze crazes or cracks all over the surface and allows water to penetrate to the body. The reason is that the koalins require flint, felspar, or stone to open them, and exposure to a long continued and steady heat before they are thoroughly burnt in the biscuit state. They also require a hard fritt or porcelain glaze, which cannot be prepared without expensive machinery, the firing also involves a great consumption of fuel as the heat must be kept up steadily for 40 or 60 hours. —M. E. J. R.

(530) CERAM LAUT ISLES. A cluster of islets lying off the south eastern extremity of the large island of Seran, or Ceram in lat.  $3^{\circ} 55' S.$  and  $133^{\circ} E.$  They produce tortoise shell, mother o pearl shell, beche de mer, wild cinnamon, wild nutmegs, and birds of paradise. —*Jour. Ind. Arch.* p. 690.

(531) CERVUS. At the Paris Exposition of 1855 of the Cervidæ, there were exhibited the following :

*Cervus Muntjac.* Kadang Kijang Malay.

*Cervus Kuhlii.*

*Cervus Moluccenses.*

*Cervus babrussa.* Rusa, Malay.

*Cervus axis.* Spotted Deer.

*Cervus equinus,* inhabits Borneo.

*Moschus Memina.* Naper Malay and Javanese.

*Moschus Javanicus* Kauchil Malay.

*Moschus Kauchil* Palandok Malay.

*Antilope depressicornis.*

*Cervus Duvancellii,* bara singha ;

*C. Aristotelis,* Ek ;

*C. Hippelaphus,* Sambur.

*C. Vaginalis,* Kaher or barking deer ; muntjac.

*C. porcinus,* jungle sheep or hog-deer.

*Rapports du Jury mixte international,* p. 54.

(532) CEYLON. The following notes upon the Vegetable Productions of the island of Ceylon were thrown together in the Journal Royal Asiat. Society 1856, part 2, Vol. XVI. Art. XIV, as a brief notice of the Vegetable Produc-

(ions of Ceylon, by John Capper. M. R. A. S. tread March 6th, 1852) in the hope that, without entering upon minute or technical details he might give a concise and simple detail of the growth, locality and value of each article of production.

These articles are as follows: coffee, cinnamon, coir, sugar, rice, tobacco, cotton, areca nuts, cocoanuts, cardamoms, pepper, arrowroot, maize, manioc, fine grains, arrack, coconut oil, essential oils of cinnamon, citronella and lemon grass, dyewood, ebony, and other furniture woods. It is a fact worth noting that of the above only one article has been introduced into the island by Europeans during the 350 years they have been connected with it. The sugar-cane was brought to Ceylon from the Mauritius by a merchant of Colombo, about twenty years since. It may, perhaps, not be without use if the above products be classified under three heads: those which are chiefly exported to Europe: those which are shipped to the adjacent states of India as well as used on the island; and such as are only produced for local consumption. The first class comprises coffee, cinnamon, coir, sugar, cardamoms, dyewood, ebony, coconut oil, and essential oils. Of these the most important by far is

(533) *Coffee*. When Ceylon became a British possession it was considered as valuable only for its pearls and spice: at the present time the pearl fishery of the island has ceased to be productive, whilst the trade in cinnamon has sunk into an almost profitless speculation. Coffee is now the great staple of the island, and deservedly ranks first on account of the money value of the yearly exports, not less than the great number of persons, both Europeans and natives to whom it affords a regular employment. When the Portuguese first settled in the island, in the early part of the sixteenth century, coffee was found growing in many parts of the hilly districts of the interior though entirely uncultivated, and only known to the priests who reared it in their temple gardens, and prepared a medicinal beverage from the berry. The Portuguese settlers in the East paid far more attention to religious than to agricultural or commercial matters, and we accordingly hear nothing of coffee as an article of culture or trade, until late during the Dutch rule in Ceylon. Even at that period it seems to have been shipped to Holland rather as an object of curiosity, and up to the close of the Dutch administration of the island the entire yearly quantity said to have been grown throughout the country was 2,200 cwts. though one of the Dutch revenue officers, in his report to the government, gave it as his opinion that ten times that quantity, or 22,000 cwts. might possibly be produced annually. The yearly crops have of late amounted to 300,000

cwts. Although the British government obtained possession of the maritime provinces of Ceylon from the Dutch in the year 1796 the interior or Kandian province was not ceded to the crown until 1815 and, inasmuch as coffee will not grow to any extent in the maritime or low country, it follows that no improvement could take place in this culture until after the latter period, when the hill districts become tranquil and were gradually opened up by good roads. From 1820 to about 1830 the quantity of coffee shipped to England yearly increased, although it still consisted entirely of the native grown, badly prepared berry, reared without any attempt at cultivation, and ranking below almost every other kind of coffee. In 1830 the first attempt at coffee-cultivation and curing was made on a proper scale by the governor of the island, Sir Edward Barnes. The success which attended this experiment, although partial, added to the lowering of the import duty on British East India coffee by the imperial legislature in 1835, and induced several merchants and others to apply for waste forest land, for the cultivation of coffee on the West Indian principle. During 1836 and 1837 upwards of 7,000 acres of crown lands were purchased, and partly cleared and planted. The success of these first operations drew many capitalists to Ceylon for similar purposes and the land sales which in 1838 amounted to 10,000 acres grew to 78,000 acres in 1841. By the end of 1847 when fresh operations had ceased, about three millions sterling appear to have been invested in coffee planting in this island chiefly by Europeans. The number of plantations formed was 337, the majority of which contained from 120 to 300 acres of cultivated coffee. The total acres brought under this culture up to 1849, were 50,840; of which, however, several thousands had ceased to be productive. These estates are situated at a great variety of altitudes ranging from 1,000 to 4,500 feet above the sea level. As a rule, good coffee cannot be profitably grown in Ceylon at a less altitude than 2,500 feet the most favourable height being from 3,000 to 3,500 feet. The best plantations are situated in the Kandian province where the thermometer ranges at noon about 76, and in the morning not higher than 60. The principal drawback to the success of these properties has been the absence of roads in many directions, compelling the planter to convey his half dried crop on the heads of coolies, or on the backs of bullocks, for a distance of 25 to 35 miles, before finding any carriage transport. The dampness and coolness of the hill climate renders it impossible to perfectly cure the Coffee berry in those elevated regions; it has therefore to be conveyed to Colombo, where a constant high temperature enables the merchant to complete the drying process, which

the planter had but commenced. In this way, a crop of Coffee costs as much to transport it from the estate to the place of shipment, distant about 100 miles, as it will to convey it thence to England. The labour by which these properties are cultivated is almost entirely imported from the adjoining coast of India, a few Singalese occasionally assisting to gather the crops, when a high rate of pay is held out to them. The coffee thus grown under European superintendence, is known in this country as "Plantation" kind, whilst that which is still allowed to grow wild about the Singalese villages, gathered half ripe and rudely cured, is known as "Native" or ordinary Ceylon coffee. The quantities of the two sorts exported to Europe of late years have been as follows :

In 1848.....	Cwts	280,000
1849.....	„	328,000
1850.....	„	319,000
1851.....	„	273,000

of which above two-thirds were plantation coffee. The island consumption amounts to about 25,000 cwts. during low prices ; but when coffee becomes more in demand, the natives content themselves with using the black and damaged pieces picked out from the marketable berries. This circumstance will partly account for the shipments of 1848 and 1851, both years of lower prices than in 1849.

(534) *Cinnamon*. From the earliest period at which any record existed concerning the use of this spice, and which extends back to the days of the Roman republic, up to the year 1769, during the latter portion of the Dutch rule in Ceylon, cinnamon grew in a wild state, amongst the thick jungles of the low and hilly country, the best always having been cut upon the light soil of the maritime provinces. The Dutch governor Falek was the first who attempted to bring the wild plants into a cultivation, amidst much opposition from the native chiefs. His plan however, only extended to draining the land and freeing the bushes from weeds and low jungle, so as to admit the light and air around them. Nothing further appears to have been done until the island had been in our possession twenty years, when extensive improvements took place. Large tracts of cinnamon land were cleared and opened by the hoe, and after draining, the vacant spaces were filled up with young plants. The low country headmen were induced to co-operate by means of promotions and honorary rewards and by these means the government, into whose hands the culture and trade had always been vested, found itself in possession of five tracts of well planted cinnamon, varying in extent from 6,000 acres to 600 acres, the yearly produce of which rendered supplies from the wild bushes of the forests no longer necessary. This spice is to be found

only in the western, southern and central provinces, and there appears little doubt that it was the abundance of cinnamon growing on the west coast of the island, which induced the first Portuguese settlers to fix the seat of their government at Colombo a spot devoid of any harbour or shelter for shipping. In 1833 the trade in this article was thrown open to the public, and six years later the government commenced the sale of their preserved plantations by monthly auctions. In this way the whole of them with but one exception, have been disposed of chiefly to English merchants and capitalists. In some cases, the gardens, as these lands were called have been brought into a much higher state of cultivation than was previously the case ; but in frequent instances they are much neglected ; and upon the whole, the quality of the spice as now shipped, will not bear comparison with the produce of former years. The forests are still searched for the jungle cinnamon, by the natives, especially when there happens to be a little better demand for the spice ; but the quality of this sort is far below that of the cultivated bark, as much as three-fourths of it being generally devoid of any flavour or aroma. The cinnamon gardens afford employment to a considerable number of Singalese at most times of the year, both for cultivating the bushes, and for preparing the crops, which are taken off twice annually, during the rain attendant on the change of each monsoon. These croppings or peelings continue for about five months in each year and a great portion of the remaining seven months is required for putting the gardens in order. Amongst other recent improvements may be mentioned pruning and manuring the bushes ; these have in some instances, brought the produce of an acre of land from 50 lbs. to 350 lbs. of spice during the year, and this too upon considerable tracts. The operation of peeling, or removing the bark from the stick, is performed by one particular caste of natives called "Chalias," a low class of persons whose ancestors were originally appointed to the duty by the Singalese kings ; and who until lately enjoyed many privileges and exemptions from taxation, in consideration of their services. The trade in this spice has fallen away sensibly of late years, in spite of the efforts made to save it by liberal reductions of the export duty. During the early part of the Dutch rule in Ceylon their yearly shipments amounted to 10,000 bales, of 88 lbs. each, of which 2,000 were for India, Persia and Arabia. These latter places have long ceased to take any cinnamon, whilst the exports to Europe have been reduced to 7,000 bales of 100 lbs. in 1849, 6,000 bales in 1850, and 5,800 bales in 1851 although the selling price in the London market has been brought down to about one-third of that realized

twenty years since. In 1835 the export duty in Ceylon was 2s. 6d. and 2s. according to quality; it is now only 4d. per lb. on all sorts.

(535) *Coir and Coconut Oil* being both the products of the cocoanut palm or *Cocos nucifera*, equally exported to Europe, may be noticed together. The palm tree may be seen in almost every part of the island but its favourite locality is the low country within twelve or fifteen miles of the sea coast. The natives believe most firmly that these trees will not thrive out of reach of the sea beach and the salt spray from the ocean; and accordingly, when planting their young palms at any distance from the coast they place a quantity of salt about its roots. That this is erroneous may be seen by examining those trees nearest the sea "they will be found far less fruitful than those a short distance away. The fact is that the soft roots of the coco palm grow more rapidly in the light sandy soil of the low country whilst at some distance inland the ground is too hard for them, and the temperature too low, especially at night. They are chiefly to be found skirting the coast from Calpentin in the north west province to Matura in the southern province. The natives have been accustomed to treat these in the same manner, as their coffee and cinnamon, leaving the young plants to take care of themselves, exposed to the destructive attacks of wild animals and insects. In this manner twelve and often twenty years are required to bring a cocoanut tree into bearing, the wonder being that these neglected palms ever bear fruit at all. Of late years European capital and skill have been brought to bear upon this produce with remarkable results. In the western province about 6,000 acres are now covered by fine cocoanut trees, many in bearing at their fifth and sixth years. In the northern province about 10,000 acres have been cultivated in the same manner, whilst on the eastern coast from 3,000 to 4,000 acres are similarly planted. The ordinary yield of a good tree in full bearing is 50 cocoanuts yearly; many trees on European lands produce from 150 to 200 per annum. For the European market the tree is only available as producing coir, fibre, and rope from the outer husk of the fruit and cocoanut oil from the kernel when dried in the sun. The manufacture of cordage and rope dates back before the Portuguese period. During the Dutch rule this was an important branch of native industry, and the trade in them became a source of considerable profit to those servants of government who were allowed the monopoly as a remuneration for their services. When properly made from good fibre coir rope is very soft and of a bright yellow colour, but in quality the manufacture of the present day cannot compare with that of the old Dutch time. In Ceylon scarcely any other rope

or cord is used than coir; even the planks of the Singalese trading *Bhories* of 50 to 100 fons are fastened together by coir yarn alone. This manufacture is confined to certain districts between Colombo and Galle along the south coast. Coir is exported to this country not only in yarn and rope, but in the fibre in bales closely pressed "the total shipments of all sorts have lately been about 30,000 or 40,000 cwts. to Europe and 20,000 cwts. to the state of India and colonies. The manufacture of cocoanut oil for shipment to Europe has only been carried on during the last twenty-five years although long previously made by the natives for their own use. The bullock mill employed by them to crush the nut and express the oil is of the rudest make and has remained unimproved for the last 500 years: a good description of it may be seen in Davy's account of Ceylon. The first steam oilmills and hydraulic presses were erected by the Government in 1829 and when found to work well, and the article had become known and valued in this country the establishment was sold to private parties. This oil has ever since assumed an important place amongst the exports of the island. In 1849 the quantity shipped to England was 512,457 gallons, in 1850, 792,791 gallons and in 1851, 322,500 gallons. It is this oil which forms the foundation of Price's Patent Candles: it is also much used by soap and pomatum manufacturers. The quantity consumed in the island must be annually about half of the above quantities.

(536) *Sugar* as already observed is the only article the manufacture of which has been introduced into Ceylon by Europeans. The first canes planted with a view to the manufacture of sugar were carried thither from the Mauritius in the year 1832; they were planted in the central province, in the valley of Dambara. The first few acres produced abundantly and of a good marketable quality, prices in the country being then high the early shipments left a fair profit, whilst that sold on the spot paid handsomely. Several sugar estates were a few years later formed in the Kandyan country and eventually eight or ten plantations of some magnitude were commenced in the southern and western provinces. Experience has shown that although one or two good crops may be obtained from newly planted land, the soil is naturally of such a poor nature as to render after cultivation hopeless without an outlay for manure which the crops will not justify. From 1846 to the present time sugar cultivation has been gradually abandoned and at the present time there are but three estates in partial cultivation, and that almost entirely for local consumption. The largest quantity shipped to England in any one year was 10,000 cwt.

(537) *Cardamoms* are collected by the na-

tives in the central and some parts of the southern and western provinces from plants growing in a wild state amongst dense forests or low jungles. In appearance and strength they are inferior to those brought from the Malabar coast, and sell here for about one half of the value of the latter. Very little care is given to their drying and packing, which is of course injurious to their appearance, and there can be little doubt but that were the plants grown in the many village gardens, together with other produce, a very marketable article would be the result. The shipments of this do not exceed 100 to 150 cwts. annually.

(538) *Ebony* is found in great abundance in the north of the island, and to some extent in the Kandyan country. The great weight of the timber renders its transport very costly unless where water conveyance can be obtained which is seldom the case but during the rainy months. Immense forests of this wood are still existing in the island but to a great extent too far from a port of shipment to be available. The exports of ebony have varied much of late years from 15,000 to 5,000 cwts.

(539) *Sapan or Dye Wood* is shipped to this country where it is employed as a red dye. The tree of which this is the mature woody part, grows abundantly in the western—southern and central provinces, without any cultivation. It is fit for cutting when about five years old, at which time it attains a height of ten or twelve feet. The exports have been for the last few years about 6,000 cwts. annually.

(540) *Essential Oils* of cinnamon, citronelle and lemon grass are made chiefly in the neighbourhood of Galle in the southern provinces. The oil of cinnamon is also made largely at Colombo: it is, obtained from the broken or inferior pieces of bark rejected in packing the bales of spice. The other oils are the produce of two highly scented grasses cultivated to a considerable extent by both natives and Europeans for the purpose of distillation. The extent of the trade in these may be thus stated, say for 1849 oil of cinnamon 32,400 ounces, oil of lemon grass 28,000 ounces.

The second division of this paper includes tobacco, preca-nuts, cocoanuts and arrack as articles exported only to the neighbouring states as well as consumed upon the island.

(541) *Tobacco* is cultivated with some attention and success by the Singalese of the western province, the Kandyans of the interior and the Tamils of the northern districts of the island. The Dutch bestowed some care upon this article but they do not appear to have succeeded in obtaining tobacco suitable to European markets. At the present time the natives frequently prepare a leaf which is mild and fragrant in use although unsightly in appearance, but the bulk of the tobacco is coarse and rank.

This arises from no want of labour expended in the culture but rather from the leaves being gathered when too old and from imperfect curing.

The Singalese are very careful in the selection of ground for this plant as well as in its treatment prior to and after planting. Manure is applied to the land in the first instance and once or twice to the young plants which are also kept constantly watered during dry weather. Not a weed is allowed to appear amongst them and every care is bestowed that is likely to forward their growth. The gathering and drying processes are managed with as little discretion as can be imagined. Very small attention is paid to the state of the weather at the picking time and when gathered the leaves are left in heaps until they commence to ferment, when they are suspended on strings or the stalks of the coconut leaf. One estate has been formed by a European in the southern province, but at present with doubtful success. The principal export of tobacco is to the Travancore country on the Indian continent, a little goes eastward and some to the Maldivé Islands in exchange for saltfish, shells, and mats. The yearly shipments have of late amounted to about 22,000 cwts., at one period they reached 40,000 cwts.

(542) *Areca or Betel nut* have for a long period formed a large item of the export country trade. These nuts are used by nearly all Asiatics who masticate them with a little lime much in the same way as tobacco is used by sailors. The first luxury which a young Singalese or Malabar indulges in is a metal betel box worn in the girdle and those who are too poor for such an ornament content themselves with wrapping their daily supply in a leaf. The areca palm which produces this nut is one of the most graceful of that tribe: it thrives at a much greater altitude and in a cooler temperature than does the cocoa-palm, though like the latter it prefers the light soil and damp heat of the low country. Although flourishing wherever the coconut tree is found, the districts in which the areca tree grows most abundantly are about the borders of the western, central and north-western provinces (between Hurriegalle and Mattele.) The fruit grows in clusters similar to those of the coconut at the summit of the tree, each tree yielding about 200 yearly. They are about the size of a large walnut and when deprived of their shell which is of no value the nut is found to be equal in size to a nutmeg. They are exported to Calcutta, Bombay, Madras, Singapoer, Penang, and the Maldivé Islands, to the yearly value of £30,000.

(543) *Cocoa Nuts* also form a prominent feature amongst the exports to Indian states, both in the raw and dried state; in which condition they are known by the name of Copperah. It is scarcely possible to over-estimate the value of

the cocoanut palm to the natives of Ceylon and other parts of India. With it they may be said to be independent of all other means of subsistence and with a little cotton for a girdle, they could exist without any other resource. Not a part of the tree is useless, every portion is made to minister to the daily wants of the grower. Oil, vinegar, arrack, toddy, sugar, medicines, are produced from the nuts and the sap of the flower. The husk of the fruit yields him fuel, fibre for ropes and cordage with which he rigs ships and canoes and secures his cattle and his fences, and when unspun forms a soft mattress for his couch. The inner hard shell is converted into boxes, drinking vessels, spoons, forks and a variety of ornaments. The wood of the tree serves to construct chairs, tables, window frames, and beams and rafters for the roof, which is thatched by the plaited dry leaves of the tree fastened down by the fresh green leaflets. These plaited leaves also form a substitute for plates and dishes. The hollowed trunk of the tree forms a good canoe in which the villager puts off to fish with a net of coir yarn whilst the smaller trees form useful spouts to carry off the rain water from the eaves of his little hut. The cocoanut when but half grown contains a rich sweet cooling liquid termed milk though as clear as spring water, around the inside of the shell is a coating of young nut soft and agreeable to the taste. These two parts of the fruit form the simple meal of many thousands of the natives. When fully ripe, the kernel thick and hard, and the milk has nearly disappeared, in this state it is employed in curries or when dried, into copperah for oil making or exporting. The shipments take place chiefly at Galle and Colombo, and amount in value to about £14,000 yearly.

(544) *Arrack* is a spirit distilled from the fermented juice of the cocoanut flower and is prepared in certain districts of the southern province of the island under licenses from the government. It is an article scarcely known in this country being very seldom imported; during the Dutch period in Ceylon a good deal of it was shipped to Holland and Java but for many years past the only exports have been to the Indian presidencies and some of the eastern islands. Until within the last ten years arrack was served out to the troops in the Madras presidency, of late however they have had in place of it East India rum. Of the total quantity of this spirit made there are no records. The right of vending it in shops or bazaars is farmed out annually in each province under the title of the arrack rent and generally realizes about £52,000. The shipments of arrack have fallen off from 1,000 pipes in 1845 to 520 in 1850. The third division of Ceylon vegetable produce comprises cotton, rice, pepper, jaggery, arrowroot, maize, manioc and fine grains.

(545) *Cotton* is grown very generally by both the Singalese and Tamil inhabitants of Ceylon but upon no regular plan nor to any extent; in some few cases the villagers produce more than they require and barter their surplus stock with the travelling pedlars for a little salt or dried-fish. In the northern and eastern districts some few landholders rear considerable patches of an inferior sort of cotton which they dispose of to the weavers of Jaffna and Batticaloa, but nearly all the cotton goods manufactured in the island are from imported yarn. Attempts have been made on several occasions to introduce American cotton seed with improved culture but as yet without any decided success. Fine samples have been produced valued in this market at from sixpence to eightpence per pound, but either from exhaustion of the soil, or the heavy cost of production these experiments have ceased. The Singalese method of cultivation is to place four or five seeds in a patch between their young cocoanut plants or plantains at the commencement of the rains in either monsoon. The seedling will be thinned out when a few inches high and afterwards weeded once or twice by hand, but no further care is bestowed upon them until the pods are ready for gathering which they will be in about three months from the appearance of the seedlings. The means used to free the cotton from its seed are as simple as it is possible to conceive. The article is placed in a rush bag held by one hand whilst with the other a cross stick is rapidly twirled round amongst the cotton tearing away the fibres from the seeds. In the north, the Tamils pass their cotton between two wooden rollers revolving slowly against each other and which draw the fibrous substance through whilst the seeds being detached fall to the ground. The staple of Ceylon cotton is very short, but of a beautiful silky texture and frequently very white. It is impossible to say with any certainty what quantity of this article is annually produced.

(546) *Rice*. Of the very highest importance to this and other eastern nations is *Rice*. It is to them what corn, and potatoes and animal food are to Europeans. Few Singalese taste much else save cocoanuts during the year, every villager is anxious to secure a patch of ground commanding water, on which he rears this essential article of food. Although the present population of Ceylon does not exceed nine individuals to the square mile it is yet found that the land does not produce nearly sufficient for the wants of the people, the annual importations of grain amounting in value to about 450,000l. Of this sum fully two-thirds consist of rice prepared or in the husk which gives about two bushels for every inhabitant, the grain being valued at two shillings the bushel. Three hundred years ago the population of the island was undoubtedly far greater than at pre-

sent yet at that period the inhabitants not only raised sufficient corn for all their wants but were enabled to export it in some quantities to the eastward. The gradual destruction of the gigantic tanks which formerly existed in the northern districts, for the irrigation of the low lands, has led to the depopulation of that part of the island whence were drawn the chief supplies of corn. To cultivate rice without a plentiful supply of water would be impossible. In the hilly districts, irrigation is carried on by means of watercourses cut along the sides of mountains or carried through bamboos across valleys often for a distance of many miles. In the low country or maritime provinces the rivers are dammed up during the rainy months, and the streams carried over the rice lands from which they are gradually drawn off by means of small channels cut in the margin of every field: of so much importance is a good supply of water for cultivation that the native sovereigns of Lunka believed they performed as righteous an act in constructing a tank or a watercourse as in erecting a temple. In Ceylon there are eleven kinds of rice grown, viz. Ratcoonda, Ballanwary, Marlawarigey, Combilley, Tattewell, Heienette, Sudheenette, Moodikiriala, Coorovie, Balla maha-vie and the Dassa-analla. The first five are sown in March and reaped in July, the next four varieties are sown at the end of the May and gathered at the latter part of July or early in August, the two last kinds are sown in November and June respectively requiring five and two months to arrive at maturity. The cultivation of rice in the low lands and the hilly regions of the interior differs in many respects. The supply of water in the maritime provinces is generally more abundant and though less to be depended on than amongst the hills added to which violent floods frequently carry away the young crops for many miles around. The soil of the lands in the interior is far more productive than that found in the maritime provinces, though in each situation varieties will be found. Many lands amongst the hills will yield two crops annually and generally one, but in the low country the ground frequently lies fallow for several years. Few fields being rich enough to produce even a crop every alternate year. The yield of crops varies greatly according to soil, aspect, water and altitude, much land produces not more than three or four-fold, whilst some of the finest tracts in the interior yield as much as forty-fold. The Singalese have very little idea of manuring their lands in some parts of the low country bones are applied on the land with success, but the cultivators are content with turning in a few bullocks upon the land during fallow season. The Singalese have many superstitions concerning their agricultural operations and never commence work without consulting the priest or the devil dancer as to a lucky day.

They hold it to be unfortunate to commence work upon the first or second day in the Singalese month and after having begun their operations they must desist for a few days at certain intervals. In like manner the threshing of the corn is attended with various observances and charms are placed around the fresh gathered crop. When a newly sown field has been reaped the owner would not dare to partake of any portion of the crop until an offering of a small portion of it had been made to the nearest temple, in order that the priest might first eat of it. The rice lands in the low country are seldom cultivated by the proprietors, they are usually given in charge to one or two villagers who with the aid of their neighbours prepare the ground and attend to the irrigation. The owner finds the seed and shares equally with the cultivator in the produce. In the Kandyan country the proprietors usually cultivate their own lands with the aid of their poorer neighbours who are paid in rice or the labour given is returned upon the neighbour's fields. Pepper although only grown in sufficient quantity for local consumption was at a former period an article of some importance amongst the exports of the island. The Dutch paid great attention to it and spared no efforts to induce its cultivation both in the low country and in the Kandyan districts. By the Dutch records it appears that during the early part of the last century the shipments of this spice amounted to nearly 50,000 lbs. of which one third was received in barter from the Kandyans the remainder was grown at Battacala, Calpenty and Negombo. Since our possession of the island pepper has never been grown in any quantity and when the government determined on shipping it loose amongst their cinnamon bales in order to preserve the latter from sea damage the spice had to be obtained from the coast of India. The little that is now grown can scarcely be said to be cultivated, it is left almost entirely to chance and consequently yields very indifferently.

(547) *Jaggery or native sugar* is produced abundantly in the northern districts of Ceylon from the juice of the Kittool or Jaggery palm *Caryota urens*. The sap is drawn off much in the same manner as that from the cocoa palm, but it does not flow so readily, and to obviate this the natives are in the habit of inserting within the surface of the cut flower spike a small mixture of lime, garlick, salt, and bruised pepper. This is left on the incision for a few days, when it is removed and the flower again cut, the sap will then flow readily for several months continuously. The collected juice is boiled in earthen vessels to a certain consistency when it granulates and forms a fair sample of sugar capable of being refined to a good degree of purity. It is a curious fact that the wood of these trees which have been thus tapped is very much har-

der than that of the unemployed trees in the forests which is quite soft and spongy, the trees longest tapped are much the hardest.

(548) *Arrowroot and Manioca* are both rather extensively grown in the maritime provinces, the former being inferior in quality to that grown in the West India Islands. They are both very exhausting in their effect on the land, which in those parts of the island is seldom fertile, consequently it is but rare that more than one crop of either can be taken from the same field without long rest. From the Manioca the Singalese prepare a fine flour resembling arrowroot but much sweeter and far more nourishing. Boiled or bake with milk it forms a most delicious meal, partaking of the nature of a rich custard.

(549) *Maize or Indian Corn* is not grown to any great extent and its cultivation is confined to the eastern and northern districts. It is employed in a variety of ways, in curries, ground into meal or boiled whole as a vegetable. It is also given to the working bullocks with oil cake and cotton seed and is highly esteemed for this purpose.

(550) *Grains*. The fine *Grains* of Ceylon comprise a great variety of seeds employed by the poorer classes as articles of food. The principal of these are Koorakam, Cooloo Moongatta, Pama Abba, Ammodo. They as well as an inferior description of Rice called Hill Paddy are grown on poor lands and yield a very small return often not more than three fold. They are used in various ways, some being eaten in curries, some simply boiled, whilst others are ground, and the flour made into cakes or bread. These grains require no irrigation though their yield depends upon the quantity of rain which may fall during the early period of their growth, and from the poverty of most of the soils on which they are raised whole crops are frequently lost in a very dry season. In the sowing and harvesting of these products the Singalese observe no ceremonies and hold no superstitions regarding lucky days or evil spirits. A circumstance worthy of note as being the sole exception to their many superstitious observances.—*Jour. of the Roy. As. Soc* p. 266.

(551) *Ginger*. Mr. G. H. K. Thwaites, the superintendent, in his Annual report for September 1854 to August 1855 inclusive writes, that the cultivation of the West India ginger in Ceylon has been successful, and that it is likely to prove ere long an important article of commerce, that the vanilla succeeds in the gardens and has produced abundance of fruit, that the cochineal insects did not thrive. The Manilla hemp, the China grass cloth plant, and the Durian trees, were growing well. There are several oils which might be exported from the island. Among these he notices Keena oil obtained from the seeds of different species of *Calophyllum*; Meeriya oil yielded by

the seeds of several species of *Isonandra*; and Madol oil from the seeds of a species of *Garcinia*. The resin called Doon-Doommalle is also likely to be a valuable article of commerce. Attention is being directed on the island to the preparation of fibres from species of *Musa*.—*Edin. New Phil. Journ*, Vol. III. No. 41. April 1851, p. from 364 to 365.

### (552) CHUSAN SHELLS.

Described by W. H. BENSON, Esq., Bengal Civil Service, Collected by Dr. T. Cantor. Under the head "Mollusca" will be found a tolerable list of the Molluscan animals of the countries to which this work relates, but we give here merely a few of the shells of particular localities.

List of Shells, presented to the Museum of the Bengal Asiatic Society by Dr. Cantor, in 1842.

#### 1.—From Chusan.

*Helix*, *ravida*, Benson.  
 ——— *caprina*, Benson.  
 ——— *nanoides*, Benson.  
*Clansilia* *pluvialis*, Benson.  
 ——— *aculus*, Benson.  
*Achatina* *erecta*, Benson.  
*Planorbis* *papyraceus*, Benson.  
 ——— *hemisphaerula*, Benson.  
 ——— *compressus*, Hutton.  
*Limnaea* *pluictula*, Benson.  
 ——— *minor*, Benson.

*Achatina* *erecta*, Benson.  
*Succinea* ——— ?  
*Littorina* ——— ?  
*Littorina* ——— ?  
*Mytilus* ——— ?

#### 3.—From various localities.

*Placuna* *placenta* ?

This shell is used by the Chinese as a substitute for panes in windows. Several junks loaded with these shells, arrived at Chusan, in 1840. They were said to be collected on the shores of Formosa, and the Loo-choo Islands.

*Placuna* ? Found in a house in Ting-hea.  
*Pecten*. Found in a house in Ting-hae.  
*Halotis*. From the Island of Quel-paert.  
*Agaricia*, (Lamouraux). This beautiful un-

## CHUSAN SHELLS.

described Madrepore is said to inhabit the shores of Chin-choo. (Fokien Province).

The following memoir was written so far back as 1841, and was embodied by Dr. Cantor in his 'Descriptive Catalogue of animals collected at Chusan' drawn up by order of Government, as already explained in an editorial note which will be found at p. 624, of the last Vol. of this Journal. Dr. Cantor's report was not as intended, published at a time when the result of his observations would have excited the most interest, and what were novelties in 1841, have subsequently been described and made known, by other Zoologists. Mr. Benson's memorandum, however, on the Chusan Shells is so complete in itself and so likely, notwithstanding the time which has elapsed since it was written, to prove of assistance to Indian Conchologists that the Editor has obtained the author's permission to publish it.—ED.

### (553) INCILARIA Nov. gen.

From *Incile*, a gutter, with reference to the gutter-like channel, which divides the mantle from the foot.

Corpus elongatum, postice attenuatum, repens, undique velo marginatum. Tentaculis quatuor, superioribus oculiferis, inferioribus integris. Foramen commune latere dextro non procul ab extremitate antica veli situm.

This animal is clearly not a slug (*Limax*), from the occurrence of a general, instead of a partial shield which covers the body nearly to the extremity like a mantle. It differs, however, from *Onchidium*, Buchanan, *Vaginulus*, Cuvier, and *Veronicella*, Blainville, in having the common orifice at the right side and near the posterior extremity under the mantle, but in the anterior part of the mantle as in *Arion*. From *Onchidium* it differs also in having the lower tentacula or appendices whole, and not bifurcate or palmated. The animal forms a connecting link between *Arion* and *Onchidium*. I have not access to any description of *Phylomique* or *Eumele*, indicated in p. 153, Rangs Manual des Mollusques, as brought to De Ferrussac's notice by M. Rafinesque.

### (554) INCILARIA BILINEATA, Benson.

Corpore livido, velo punctis maculisque fuxis conspersis ornato, lineis duabus lateralibus nigrescentibus, unico obscuriore mediano strigato.

"NOTE.—Dr. Cantor's notes on habitat, locality, uses &c. and included in the lines with inverted commas. "Found in the earth under the roots of trees. Great numbers were seen at night above ground on plants and trees, also on rainy days, when they appear suddenly. This slug appears to be a favourite prey of a toad (*Bufo gargarizans*, Cantor) which swarms at night, and on rainy days, and I once observed a spider, (*Latrodectus limacida* Cantor MS.) seize one of these slugs. The Chinese apply the slug as a poultice for bruises, &c. The

## CHUSAN SHELLS.

respiratory orifice is very minute. The sketch represents a good sized specimen creeping on *Stillingia sebifera*"

### (555) HELIX RAVIDA, Benson.

Testa subglobosa, umbilicata, epidermide olivacea, anfractibus sex transverse subplicatis, ultimo ventricoso, suturis impressis, umbilico mediocre; apertura suborbiculari elongatiuscula; labio reflexo, tenni explanato labro acuto.

Axis 1.3.—Diam. 1.33.

This shell is nearly related to *H. pomatia*, but has more depressed whorls, and a shorter spire in proportion. The apex inclines more to a point than in *pomatia*. It has not the thickening of the peristome which is so marked in that species.

The colour, sculpture and smaller size also serve to distinguish it. The length of the aperture slightly exceeds the breadth. The colour of the epidermis in the lower whorl is more saturate than in the upper ones.

"Inhabits trees, mossy stones, rocks, crevices and the earth; common at all times in shady places, particularly abundant at night, early in the morning and on rainy days. The animal is used by the Chinese in headache, and for bruises. The shell is removed, and the animal applied to the suffering part."

### (556) HELIX TAPEINA, Benson.

Journ. Asiatic Socy. Vol. 5, p. 352 No. 7. This shell was originally described with a collection from the N. E. Frontier of Bengal, in which Chinese forms began to mix with those of our eastern provinces.

"Only two specimens, which occurred on the stem of *Salisburia genko*, were found, at sunrise. The Chinese had no name for the snail, and were evidently not acquainted with it, from which it would appear not to be common."

### (557) HELIX NANINOIDES, Benson.

Testa solidiuscula, subdiscoidea superne radiatum, tenuiter striata infra striis laevigatis, distantibus. Spira depresso-conoidea, apice obtusato planulato; apertura transverse lunata labro obtuso crasso, infra subreflexo.

This shell is nearly related to, and is probably one of the terminal species. The want of gloss, observable above, shews that it is not endued with the lubricating processes which exist on the mantle of *N. vitrinoides*. The under side is somewhat polished.

Dr. Cantor found three shells at different times lying on the ground in his garden at Ting-hae but never saw it alive nor did the Chinese know it. It is common at Singapore and Penang.

### (558) CLAUSILIA FLUVIATILIS, Benson.

Testa fusiforme pallide olivacea, spira attenuata, crystallina apice papillari; anfractibus 14, medianis ventricosisioribus, omnibus leviter transverse striatis. Peristomate valde reflexo planato, ad basin labii plica obliqua, solida, sulcoque concurrente munito.

## CHUSAN SHELLS.

Axis 1. I poll.

This beautiful shell, which is much larger and more narrow in the upper whorls than *C. loxostoma* of our N. E. Frontier, is distinguished by the curious canal which cuts obliquely through the reflected peristome at the base of the inner lip, and which is margined above by an incrassated prolongation of the lowermost internal plica. The peristome is as broadly and suddenly reflected, as in the Maltese *Cl. labiosa*. In form it approaches the Dalmatian species *Cl. laevigata*, but it is more ventricose in the lower whorls, and more attenuated in the upper. The delicacy of the oblique striæ imparts a silky lustre to the epidermis. The base of the shell has an oblique keel at the back of the canal on the peristome, as in *Goniostoma*, Swainson (*Bulimus goniostoma*, Sowerby. Zool. Journ. Vol 1.) Swainson has placed *Clausilia* among the *Achatinidae*, and the discovery of this interesting species will go far to prove the propriety of the location. This shell represents the subgenus *Goniostoma* in the neighbouring group of *Bulimus*. Among the *Achatina* proper it would seem to represent *Achatinella*, in which the emargination at the base of the inner lip is fortified by a thickening of the base of the columella.

This *Clausilia* was only observed after heavy and protracted falls of rain when Dr. Cantor found at different times three specimens lying on the ground. Eight other specimens were found by digging in the wet earth, where they appeared in company with the smaller *Clausilia aculeus*. The animal is like that of *C. aculeus*, and differs only in size, and in being of a greyish black colour.

(559) *CLAUSILIA ACULUS*, Benson.

Testa subulata nitida, epidermide fusciscenti, anfractibus 10 aut 11. oblique leviter striatis; apertura dentibus duobus vel tribus munita, peristomate reflexo.

Axis longioris 0.65, minoris 0.5 poll.

There are two sizes of this shell; the dwarf kind appears to be the more abundant. It varies in the presence or absence of the lower plait or tooth, as do some of the European species. Neither of the larger specimens, which I have under inspection shews any trace of it while in the dwarf variety it is more frequently exhibited than otherwise. The specimens appear to be by no means liable to truncation.

"Lixer in the earth on mossy stones, walls and trees. Appears in great numbers in rainy weather. The Chinese call this species by the same name as *C. pluvialis*."

(560) *ACHATINA ERECTA*, Benson.

Testa albida, solidiuscula, subulato turrata, epidermide foeda, scabra, anfractibus octo planulatis, suturis impressis, apice obtuso.

This shell belongs to the same division as, and is closely allied to our Indian *Bulimus*

## CHUSAN SHELLS.

*gracilis*, Hutton, and *Bulimus clavulus*, of the West Indies, which Sowerby arranges as an *Achatina*. In all these shells there is a slight evasion or sinuation of the base of the mouth, occasioned by the protrusion of the outer lip; but in none of them is there the decided truncation of the base of the columella which distinguishes the true *Achatina*. Dr. Cantor's shell approaches most nearly to those forms of *Achatina* which are represented by *A. octona* (subgenus *Macrospira* Swainson,) but it cannot, notwithstanding its elongated form and oblong aperture, be received into Swainson's subgenus *Leptospira*, by which he makes the transition to *Achatina* from *Bulimus* with reference to the character assigned by him to the outer lip of *Leptospira*; and it agrees still less with his figure of *L. signata* which possesses an exerted aperture with a free border. It is nevertheless not distantly related to *Bulimus decollatus*, which he would place in that subgenus. In one adult specimen sent, the inner lip and base are considerably thickened by a deposition of shelly matter, added like an anterior lip after the animal had attained its full growth. In its habit of carrying its shell erect, the animal differs from our Indian species which although it occasionally lifts its shell a little, ordinarily trails it behind.

"Invariably found in company with *Clausilia aculeus*. Except in colour, the animals are alike. In habits they differ only in one respect. The *Clausilia* drags the shell along with the apex touching the ground, while the other carries the shell erect on its back. *A. erecta* was also found by Dr. Cantor at Macao, although not accompanied by the *Clausilia*, which he only met with at Chusan.

(561) *PLANORBIS PAPYRACEUS*, Benson.

Testa compressa, olivaceo-cornea, sub polita, minutissime radiato-striata, anfractu ultimo latiori, supra infraque æqualiter, convexo; periphæria carinata, spira basique ambabus depressis, umbilicatis; umbilico inferiori rectiori; labro superiori valdè prominente, semicirculari; inferiori recedente, recto.

Diam. O. 4. poll.

"Found in canals and ponds attached to *Chara*; not numerous. It is to be observed that the canals at Chusan communicate with the sea (those of Ting-hae of course more immediately so,) and although the water is fresh and inhabited by frogs, fresh-water fishes, *Dytiscus*, *Nepa*, and covered with *Lemna* and *Chara*, yet it is mixed with salt-water in the vicinity of the sea, which may account for the appearance of marine Crustacea and Testacea."

Whorls 4 in number. This shell seems to take its start between the depressed *Planorbis* (as *marginatus*, *carinatus*, *spirorbis*, *vortex*, etc.) in which the angle of the penultimate volution scarcely enters the mouth of the shell, and the Sylhet species *umbilicalis*, the English *nitidus*,

## CHUSAN SHELLS.

the Bengal *trochoides*, in which the angle of the penultimate whorl projects far into the cavity of the mouth. In its compressed form it assorts with *carinatus*, while in the character just noted, in the great comparative breadth of the last whorl, and in the somewhat contracted umbilicus it approaches to *umbilicalis*. The arcuated and nearly semicircular upper lip forms a bow, of which the straight lower lip replaces the chored, and joining on to it at the sharp periphery, gives the mouth a very singular appearance. "Dr. Cantor has lately discovered at Serampore and Barrackpore a new species, belonging to this type of form which is closely allied to *umbilicalis*."

In this description, I have considered the shell as dextral. On a former occasion I gave my reasons with reference to the position of the animal in the shell, and Mr. Gray, who quotes my observations, states that M. Desmoulins who has examined the question in detail, concludes that the shell of *Planorbis* is essentially dextral, and that a displacement to the left side of the extremities of certain organs which are themselves on the right side has led to the erroneous opinion, derived from imperfect anatomical investigation, that the animals were sinistral. Swainson, somewhat strangely seemed to be unaware of this investigation, when he noted that one of the characters of *Planorbis* was a reversed aperture. I have not referred this shell, nor the next, to any of his sub-genera of *Planorbis*. He evidently has not worked them out, nor traced their analogies to the families of the *Phytophaga*. This sub-genera *Planorbis* and *Helisoma* appear to be scarcely distinguishable by their descriptions, as will appear from the following table, in which I have merely transposed all that Swainson says regarding them for the sake of the juxta-position of the characters, putting my own observations within brackets.

Sub-genus *Planorbis*, Drap.

*P. corneus*.

1. Spiral-whorls few.
2. Body-whorl ventricose
3. (Note, This may be said to be the case in *Pl. corneus* it matters not which side be regarded as containing the apex)

Sub-genus *Helisoma*,

Sow. *H. bicarinata*,

1. Whorls hardly three.
2. Shell ventricose.
3. The spire sunk below the body-whorl.

I have not Sowerby's Genera to refer to for the type of *Helisoma*, but if it be intended for the reception of forms similar to that next to be described, and which is par excellence, of the Heliciform type; and if *Helisoma* be an unclassical abbreviation of the hybrid word *Helicosoma* in allusion thereto, then the depression of the spire must have reference to the depth and construction of the umbilicus on the really lower side, and the character "shell ventricose" must refer to the convexity (in the more typical species) of the upper side of the shell. If Swainson

## CHUSAN SHELLS.

should not have intended to characterise this type, I would propose the term *Helicorbis* for it, and would offer the following incomplete sketch of an arrangement. I have omitted *Segmentina*, Fleming; as though its singular internal divisions make it represent the *Cephalopoda*, yet its form does not separate it from the sub-genus in which *Planorbis nitidus* will be found, and it is not representative, quoad that structure, of any of the families of the tribe to which it belongs.

Families of the *Phytophaga*. Analogies. Subgenera of *Planorbis*.

1. *Helicidae*. Typical. *Helicorbis*? Benson.  
*H. hemisphaerula*, Benson.  
*H. nitida*, Gray's *Turton* Pl. 8. f. 93.  
*H. umbilicalis*, Journ. As. Soc. 5 p. 741.  
Aberrant. *H. papyraceus*, Benson.
2. *Trochidae*. Subtypical. *Trochorbis*, Benson.  
*Trochorbis trochoides* J. A. S. 5. P. 742.
3. *Halitidae*. Spire evanescent, Aperture patulous. *Planorbis*.  
*P. corneus* auct.  
*P. indicus*, Benson J. A. S. 5. P. 743.  
*P. corpulentus*, Say. Append. to exped. to St. Peter's River. Pl. 15. Fig 9.
4. *Naticidae*?\*
5. *Turbinidae*. Aperture rounded not encroached upon by the previous whorl. *Omalodiscus*, Benson.  
(† *Spirorbis*, Swainson)  
*O. marginatus*; *Spirorbis albus* &c.

\* Is this family a fair representative of the *Cypræidae* among the *Zoophaga*?

† This name having long been pre-occupied by a genus of *Annelides*, Swainson's sub-genus requires a change of designation. Swainson has also called a genus of the *Olivineæ* "*Scahula*," without observing that, in 1834, I applied the name to a fluviatile form among the *Arcadæ*. Zoolog. Joura. Vol. v.

(562) *PLANORBIS HEMISPHERULA*, Benson.

Testa nitida, olivaceo-cornea, supra convexa, apice planulata, infra excavata, umbilico coarctato; periphæria obtusa, nullo modo carinata. Diam. o. 25 poll.

This species, belonging to the circle of *Helicorbis*, is nearly related to the *Sylhet umbilicalis*, but differs in colour, in its greater convexity and narrower umbilicus. The periphery is rounded, not angulate; the spire has no depression below the surface of any of the whorls, while the underside is concave. I have another species of the subgenus in which the umbilicus is as narrow as in *Trochorbis*, none of the previous whorls being visible. It will form the passage from *Helicorbis* to that sub-genus; it is from the Indus at Sukker, is very minute, and was accidentally sent to me, secured from injury in the hardened mud which filled the aperture of a *Paludina bengalensis*, picked up with other well known shells of the provinces by a friend, on the bank of that river.

"*P. hemisphaerula* is found in the same localities as *P. papyraceus*, on *Chara*, *Lemna*, &c. It is not numerous."

(563) *LIMNAEA Plicatula*, Benson.

Testa elongato ovata cornea scabriuscula, anfractu ultimo transverse plicatula, suturis impressis; spira mediocri, apice acuto plerumque ferrugineo; apertura infra patulante, basi evasa.

This shell differs scarcely in shape from a *Limnaea* (*L. miscella*, nobis) common in the Rivers of Rohilkhund and in the River Goomty, which approaches in some of its characters very nearly to one of the varieties of *L. chlamys*. The present species may be distinguished from *L. miscella* by the want of polish, by the more deeply impressed sutures, by the slight plications on the last whorl, and by its coloured apex.

"Found in fresh water ponds, floating on the surface, or attached to *Chara*. *L. plicatula* is common."

(564) *LIMNAEA MINOR*, Benson.

Testa ovato-acuta, cornea, polita, spira vix dimidium testae efformante; apice obtusiusculo, anfractibus quatuor, suturis leviter impressis; apertura ovata, plica columellae obsoleta.

This very distinct shell was among the specimens of the last described species. The specimen under review is a small shell, and intermediate in form between the English *L. fossaria* (*minuta*, Lam. *truncatula*, Gray) and the large species of our Western Provinces, *L. bulla*, which again is nearly allied to the Bengal species *L. luteola* of Lamarck. From *L. bulla* it differs in its comparatively greater length of spire; from *L. fossaria* by the shorter spire and slightly excavated sutures.

(565) *BULLÆA CAURINA*, Benson.

Testa ovato-oblonga, alba, tenuissima, papyracea, transverse eleganter minutissimeque striatula; apertura auriformi supra angustata, infra patulante; labro apicem superante; spira nulla.

The part of the body-whorl which is visible when the aperture is turned towards the observer is small in proportion to the mouth. The sum-

mit of the shell resembles the same part in *Bulla navium* and *B. solida*, but the outer lip is destitute of the fold where it rises above the apex, which appears in those species; resembling, in this respect *B. ampulla*. The thinness of the inner lip locates this shell in *Bullæa*. Its being internal, probably accounts for the state of Dr. Cantor's specimens from the contraction of the cooked animals, compressing the very fragile shells. The same circumstance may have occasioned the want of success met with in the search for living examples.

"On entering a house in Ting-hae where the people had just finished their breakfast, Dr. Cantor observed a number of these shells (broken with but one exception,) on a dish. To an enquiry whence they came, the Chinamen asserted, that they were taken in the canal. Although Dr. C. offered a reward and almost daily dragged the canals, he was never able to procure another specimen. The same dish contained shells of *Paludina quadrata*, which is a favorite food of the Chinese, and is plentiful in all the canals, even close to the sea; and as the canals communicate with the sea, the *Bulloea* might possibly have been found in the locality assigned."

(566) *PALUDINA QUADRATA*, Benson.

Testa elongato-conoidea, crassa, epidermide viridi-olivaceo, anfractibus sex planulatis, leviter transverse plicatis, longitudinaliter liratis; liris subquinis, apertura mediocri, intus albido-violacea, umbilico arcto, peritremate nigrescente.

The slightly prominent longitudinal ridges (which, with the flattening of the whorls, contribute to give the shell a singular appearance,) vary much in number, and in some specimens are nearly obsolete. The operculum is horny. The shell in its thickness and sculpture indicate, an approach to the *Melania*, but the animal having the eyes on an exerted pedicle, differs therein from *Melania* in which the eye is sessile on the tentaculum. It also differs from the ordinary forms of *Paludina*, in which the eye supports seem to occupy a common tube with the tentaculum, and to be truncated at the point of divergence. The ridges of the shell are frequently invested with either a vegetable or a spongy growth, which gives it an appearance of having variegated bands, which do not properly belong to the epidermis.

"Extremely common in canals and fresh-water ponds, where it is found in the mud, and adhering to stones, wood, aquatic plants or any firm object which may happen to be immersed. The specimens vary in size; larger specimens were observed, than the one figured. In the female, Dr. Cantor found from 7 to 10 young ones of different sizes. This species forms a common and favourite article of food with the Chinese, and large supplies were exposed for sale in the market at Ting-hae."

## CHUSAN SHELLS.

### (567) PALUDINA LECYTHOIDES, Benson.

Testa ovato-acuta, olivacea; anfractibus sex aut septem rotundatis, transverse subplicatis; suturis excavatis; apertura oblonga; peristomate subreflexo, nigro; apice acuto; umbilico ætate evanescente.

Nearly allied to Gray's *P. chinensis*, and to *Paludina lecythes* nobis (Journ. As. Soc. Vol. v. page 745.) It differs from the latter in its more produced form, more acute apex, the slighter convexity of the whorls, and its greater solidity. From *P. chinensis*, which has an eroded apex in the specimen figured, and which it resembles in habit, it differs in the absence of any angularity at the base of the aperture, which is also less oblique in the shell under review. In young specimens the olive-coloured epidermis has a lutescent tinge, and dark stripes accompany the plicæ of growth. The colours are darker in adults, and in one variety, the lower portion of the last whorl is ornamented by a series of light coloured longitudinal bands. In the very young shell, the aperture equals the spire in length; the spire is conoidal, and the peritrema of the last whorl, angular and sub-carinate. The same characters are observable in the embryo, but the apex, in the latter state, is produced in a papillary form.

"Lives in the mud in ditches and fresh-water ponds. Not numerous. The snail, when once removed from its native element, keeps itself shut up, although confined in water. It is a favourite food with the Chinese, who eat it prepared in the same manner as other edible snails, viz. boiled. The embryones, which vary from 8 to 12, are somewhat larger than those of *P. quadrata*, and their shells are colourless and semitransparent, whereas the embryo of the latter is frequently of a dark colour."

### (568) PALUDINA (BITHINIA, Gray) LONGICORNIS, Benson.

Testa ovato-conoidea, cornea, polita, spira aperturam longitudine vix superante; anfractibus quatuor, ultimo convexo, suturis minime depressis; apertura subrotunda, supra angulata; peristomate subreflexo, nigrescente; labio crassissimo; operculo testaceo; umbilico evanido; apice abtuso.

This shell appertains to the group of small *Paludina* which Gray has separated under the designation of *Bithinia*, to which belong the English *P. impura*, the Indian species *P. cerameopoma* and *pulchella*, (nobis), *goniostoma* (Hutton) and one or two other species, inhabiting the rivers and pools of the gangetic plains which as yet are undescribed. The present species is remarkable for the thickening of the inner lip in the part where it adheres to the penultimate whorl.

"Found in the canals in great numbers attached to aquatic plants, stones, pigs, &c."

## CHUSAN SHELLS.

### (569) PALUDINA (BITHINIA) STRIATULA, Benson.

Testa ovato-acuta, cornea, polita; spira elongata; anfractibus quinque convexiusculis, liris pluribus, interdum inconspicuis, circumdati, suturis depressiusculis; apice obtusato. Peristomate reflexo, nigrescente, undato; umbilico evanido; operculo calcareo.

This form is singular among the *Bithinia* on account of the ridges on the whorls. All the other known species, including those above named, viz. *parrula* of the West Indies, *rudis* and *rubens* of Dalmatia, *fluminensis* of Hungary, *inflata* of the Ionian Islands, and a small Sicilian species which stands in collection without a name, being deficient in sculpture. The number and degree of prominence of the ridges vary much, and they diminish in prominence in proportion to their paucity.

"Less common than *P. longicornis*, but found in the same localities. The animals and their habits are similar."

### (570) MELANIA CANCELLATA, Benson.

Testa, elongato-turrita olivacea solidiuscula; anfractibus novem convexiusculis, omnibus costulis frequentibus, ultimoque fasciis tribus elevatis basalibus munitis; costulis liris plurimus cancellatis; suturis mediocriter excavatis; apice eroso.

Axis 1.0 poll. vel paulo plus.

This little species is nearly allied to the gigantic, *M. variabilis*, nobis, of Bengal, and like it, has the sinuated aperture, which indicates the approach of the genus to the neighbouring type: *Melanopsis*. There are seldom more than seven whorls present, the apex being subject to decol-lection, which in this genus, I have observed to be an indication of residence in stagnant water.

"Nearly all adult specimens somewhat mutilated. Found in the canals close to the sea in the mud, and makes its appearance in the market, not as an article of food, but in company with the fish caught by dragging the bottom of the canals."

### (571) MELANIA (HEMISINUS? Swainson) CEREBRICOSTIS, Benson.

Testa elongato-turrita, olivacea, tenui, anfractibus plurimis leviter convexis; costis frequentissimis albidis, lævigatis munitis, ultimo costulis evanidis; balteo submediano, rugisque plurimis basalibus circumdato; suturis impressis; columella subrecta; basi leviter canaliculato-effusa; labro tenui, lævi, sub-reflexo; apice decollato. Axis testæ decollatæ 1.05 poll.

This is a very interesting shell, agreeing nearly with Swainson's sub-genus *Hemisinus*, the type of which is figured in Griffith's Cuvier as *Melania lineata* (Vol. XII. Pl. 13. fig. 4). The Chusan shell however, shews no symptom of the crenation in the aperture, which is attributed to

## CHUSAN SHELLS.

the type. The species now described leads to the sub-genus *Cerithidea*.

"Found among specimens of *Melania cancellata*."

(572) *BATILLARIA*, \* Nov. Gen.

\* *Batilla*, a shovel; from the lengthened form of the shell, and the conformation of the base of the aperture.

Testa turrita, insculpta, rudi; anfractibus plurimis, apertura oblonga, infra angustiore, basi truncata, evasa; labro sinuata, supra emarginato, infra protracto; labio supra callo munito; columella planata, basi incrassata, oblique truncata, canalem vix efformante; operculo corneo, tenui, spirali, multiverticillato.

(573) *BATILLARIA ZONALIS*, Benson.

Testa elongato-turrita, scabra, albida, fasciis fucis ornata; anfractibus tredecim mediocriter convexis, costulis liris longitudinalibus decussatis, supra sub-nodulosis; apertura intus fasciis fuscis strigata; columella alba, Axis 1.4 poll.

SYN. *Cerithium zonale*, Lam. l'océan des Antilles.

*C. zonale*, Gray, Griff. Cuv. 12, Pl. 14, fig. 1, China?

"From the coast of Chusan. Some were brought to Dr. Cantor from the entrance of the canal; but he did not himself find them in the estuary."

This shell does not agree with the characters of any of the sub-genera of the *Cerithium* in which Lamarck and Gray have placed it, and the structure of the base of the columella is almost precisely that of the *Planaxis*, Lamarck, from which the form is sufficiently distinguished from the truncation of the base of the aperture, its sinuous outline, and the absence of the interior ribs, as well as by the elongated form of the spire. Swainson has considered *Planaxis* to be a terminal genus of the *Melaniae*, and the present species in its form and sinuous lip presents characters in consonance with the typical species of *Melania*, while the columella approaches to the structure of that of *Melanopsis*. As in *Planaxis* and many of the *Cerithina*, there is a callosus attached to the penultimate whorl near the top of the aperture, and its scabrous surface and occasional disposition to form a varix on the last whorl behind the pillar, give a farther resemblance to that sub-family.

(574) *LAGUNCULA*, Nov. Gen.

Testa turbinata, subglobosa, apertura majori, integra, oblonga, peristomate interrupto, labio subreflexo, umbilico profundo, tortuoso.

(575) *LAGUNCULA PULCHELLA*, Benson.

Testa albido-glauea, ovato-globosa; anfractibus convexis, lineis longitudinalibus, elevatiusculis, aliis obliquis decussatis, instructis; suturis impressis; apertura intus fascia lata pallide castanea ornata, columellaque intus concolori.

"Asserted to be an inhabitant of the canals

## CHUSAN SHELLS.

at Chusan, and found under the same circumstances as *Venus chinensis*."

The raised lines crossing each other, give the facet-like appearance to the surface, which is frequently observable in *Limnaea*. The form of the umbilicus and the greater prominence of the raised lines near the umbilicus show an approach to the subgenus *Globularia*. Whorls 5, exclusive of the apex, which is less acute, than in *Assiminia*. The substance of the shell is thin, and it has much the aspect of a shortened *Paludina*, such as *P. crassa*. It appears to be related both to *Assiminia* in the *Turbinidae*, and to *Lacuna* and *Globularia* in the *Natioidae*. From the former it is distinguished by its more globular form, and by the openness of the umbilicus, as well as by the absence of any distinct shelly plate, adhering to the body-whorl within the aperture. From *Lacuna* it may be known by the circumstance of the umbilicus being situated about the centre of the aperture, instead of near its summit, and by the same absence of a shelly plate. From *Globularia* it is distinguished by its more lengthened form, less concave inner lip, and by the absence of a thickened belt at the base of the body whorl.

(576) *MYTILUS NIGER*, Benson.

Testa oblonga, trigona; cardine unidentato; natibus subineurvatis, decorticatis, sub epidermide albis marginibus purpurascens; intus margaritaceo-splendida, margine purpureo. Long. 3.4 poll. Lat. 1.7.

It is punctuate in the interior, especially near the beaks. There are *Flustra* on all the specimens, leading to the supposition, notwithstanding their naere, that the habitat is marine.

(577) *DREISSENA PURPURASCENS*, Benson.

Testa oblonga sub-quadrata, radiatoplicata, sub epidermide albo purpureoque ornata, intus margaritacea, epidermide brunneo, apice subineurvato, compressiusculo Long. 1.5, Lat. 0.8 poll.

The anterior margin is minutely toothed. The posterior muscular impression is curiously honey-combed, and the whole of the interior is strongly punctuate at nearly equi-distant points. The plicae or raised striae are strong within a short distance of the beaks and along the anterior side of the umbonal slope, but become obsolete on the rest of the shell. The epidermis is scabrous and covered with a minute weed, which looks like a fresh-water production. The septum at the beaks refers this shell to *Dreissena* of Van Beneden, which includes the fluviatile species *polymorpha* of Europe.

"Dr. Cantor never saw those muscles alive, but found the empty shells about the houses at Ting-hae. The Chinese said that they were found in great numbers in the canals close to the sea, but only in winter, when large supplies are brought to market. They also asserted that they attain upwards of six inches in length."

## CHUSAN SHELLS.

### (578) MODIOLA SENHOUSEIA, Benson.

Testa transverse oblonga subalata, gibba, læviuscula; antice angustata; intus iridescente; epidermide olivacea, obscurè radiata; ala nati-busque strigis flexuosis spadiceis ornatis, basi leviter emarginata. Long. 1.2, Lat. 0.6. poll.

Named by Dr. Cantor after the late Sir H. Le Fleming Senhouse, who first observed it and pointed it out to him. This gallant officer who commanded the naval forces in the attack on the city of Canton which resulted in its submission to the British arms, and who fell shortly afterwards a victim to his exertions in that engagement, was much attached to Natural History.

"Sir H. Le Fleming Senhouse observed numbers of this shell on board of one of the captured junks where specimens were obtained from the Chinamen, who had brought a large supply, preserved in salt, from the East coast of Canton Province. Dr. Cantor afterwards found two specimens on the mud among the fragments of rocks which line the coast of Chusan. People at Ting-hae were well acquainted with the muscle. Judging from the heaps of shells which lie about every house at Chusan, the people are great consumers of shell fish, and it is amusing to see how expert they are in opening bivalves, for which their inch-long nails are well adapted. Dr. Cantor later observed this shell inhabiting the shores of the Malayan Peninsula, Singapore, and Pinang.

The form belongs to the sub-genus *Brachydontes* of Swainson. A nearly allied, but much smaller, species occurs in the creeks of the Sunderbuns, which he proposes to describe as *M. Variegata*.

### (579) ANODON GIBBUM, Benson.

Testa fragili, ovata, tumida, antice rotundata, postice subalata, supra angulata, extremitate postica subangulata, natibus concentricè rugosis, rugis parallelis, sub-distantibus, area postica radiis tribus approximatis leviter elevatis, rugosisque, munita; margarita interiorius albida versus apicem aurantio-tabescenti, versus marginem purpureo-viridique splendide margaritacea; margine fusco; epidermide olivacea, obscure radiata. Long. 2.0, Lat. 3.2 poll.

This shell approaches in form and outward appearance so nearly to one of the varieties of *A. cygneum*, that at first sight, it might be difficult to distinguish them; but on opening the valves, the superior splendour and vivid colouring of the Chinese shell at once suggest a specific difference. *A. cygneum* shews vestiges of raised rays, similar to the three on the surface of *A. gibbum*, but in an English specimen, of the variety *incrassatum*, does not present the concentric rugæ on the beaks, which are exhibited by Irish specimens of another variety in which however, they are closer and more delicate than in the Chusan shell. The sub-cardinal muscular

## CHUSAN SHELLS.

impressions are more immediately under the beaks in *A. gibbum*, while in the British species they are more removed towards the anterior side.

Sometimes 5 inches in length. Very common in mud in the canals. Sold in the bazaars as an article of food. Large specimens are very brittle, and precaution should be taken to dry them in the shade."

### (580) UNIO (THELIDERMA, Swainson,) LEAH, Gray.

Testa crassa, subovata, alata, compressa, umbonibus dentibusque cardinalibus extremitati antice angustiori approximatis; valva sinistra dente cardinali interiori margineque cardinali pene parallelis; illa versus dentem lateralem medioeriter productam spectante; valva dextra dente cardinali unica creata; valvis intus minime profundis; margarita; iridescente, pallide salmonis colore tincta; natibus minime prominentibus; rugis seriebus duabus e linea umbonali divaricatis; posterioribus simplicibus, anterioribus, basalibusque nodulosis, testam exteriorem mumentibus, epidermide flavo-olivacea. Length 2 inches, breadth 3, weights of the two valves 1½ oz.

The interior lobe of the cardinal tooth in the left valve is in a line with the lateral tooth, or nearly so. The anterior impression of the adductor muscle is finely sculptured in a radiate crystalliform manner. The epidermis is slight yellowish olive, verging into light brown. The posterior margin is sinuous, owing to the ends of the nodulous radiating ribs, which diverge in 2 curved series from the umbonal slope: those towards the posterior margin and wing being simple, while those which run towards the basal and anterior margin, consist of a series of nodules. The two smaller muscular impressions of the cardinal group are in this species situated transversely, one of them being remote from the large impression but in *U. divergens*, one is situated above the other, and both adjoin the large impression.

This shell is evidently the same species as that figured by Gray in Griffith's Cuvier, Vol. XII. Pl. 21, fig. 1, but without a description. The aspect of the shell, and still more that of *U. divergens*, reminds the observer of the thick nodulous forms which inhabit the waters of North America, and is quite unlike that of any of our Indian species, only one of which attains any moderate degree of thickness.

A perfect specimen of this and a single (left) valve of the next species were found in a house at Ting-hae. They are eaten by the inhabitants who asserted that the shell is found in fresh-water somewhere on the Island. At Macao, Dr. Cantor afterwards saw a specimen with a gentleman who had received it from a native of Canton. The latter asserted that the shell inhabited the mud in the Canton river, at some distance in the interior."

## CHUSAN SHELLS.

(581) UNIO THELIDERMA, Sw. DIVERGENS, Benson.

Testa crassa, angulato-ovata, subalata, tumidiuscula, facie externa tuberculato-plicata, rugis seriebus et quibus e linea umbonali divaricantibus; posterioribus simplicioribus, anterioribus basali-busque plerumque nodulosis; natibus mediocriter prominentibus, epidermide negrescente, striis subimbricatis. Valvæ sinistræ dente cardinali interiori versus angulum marginis posterioris basalisque spectante, ad latus exterius laminis pluribus munito; dente exteriori pene obsoleto brevi, a basi interioris divaricato; dente laterali brevi crasso. Long. 2.65, Lat. 3.5 poll.

The lateral tooth is nearly parallel with the direction of the inner cardinal tooth, instead of forming, as it were a prolongation of the same line, as in the last species. The anterior impression of the adductor muscle is irregularly reticulate. Anterior margin sinuous, from the protrusion of the extremities of the rugæ. Weight of a single valve  $2\frac{3}{4}$  oz. nearly. It is not very distantly related to the American species *V. costatus*, Rafinesque (*undulatus*, Barnes) figured in Conrad's Monograph in plate No. 17.

(582) CORBICULA FUSCATA, (Lamarck.)

Testa cordata subinæquilaterali fuscovirente, tumidiuscula, polita, intus et ad nates violacea, extrinsecus sulcis crebris circumdata, rugis intersitis subimbricatis; margine interiori plerumque nigrescente; natibus decorticatis. Lat. 1.3, Long 1.15 poll.

This appears to be *Cyrena fuscata* of Lamarck belonging to the division which Megerle has separated under the name of *Corbicula*, and which is well distinguished with reference to the minutely, serrated and elongated laminar lateral teeth. The plica on the outside of the valves are more distant than in our Indian species.

"Found in the mud in the canals; sold in the market."

(583) VENUS SINENSIS, Auctorum.

Testa orbiculata, convexa, albida, marginibus violaceis denticulatis, extrinsecus radiis violaceis plicisque concentricis exilissimis ornata; disco plerumque ferrugines; dente cardinali postico, bifido sæpe bilobato, laminæ cardinalis extremitate postica concavata. Long. 1.7, Lat. 1.65.

Iron. Wood, Pl. 8, fig. 76 non bene.

In most specimens, the coloured rays are confined to the posterior half of the shell; but occasionally, they pervade the whole dish, and decussate the concentric plaits in such a manner, as to deceive the eye, and to cause the belief that there is a radiate striate sculpture. The siphonal scar cuts sharply through the sub-marginal impression, and ends in a point near the centre of the shell, as in *Artemis lincia*, and in a less degree in *Venus gallina*.

"Dr. Cantor never saw this bivalve alive, but judging from the number of shells lying about

## CHUSAN SHELLS.

houses at Chusan, it must be a common article of food. According to the Chinese, it is an inhabitant of the canals."

(584) SANGUINOLARIA IRIDESCENS, Benson.

Testa subelliptica, compressa, albida, iridescente, versus apicem incarnata, exilissime transverse striata, striis obsoletis radiatim decussata; latere postico subrostrato, subangulato, antico longiore, rotundato.

This shell has a chatoyant reflection on the exterior of the valves, of which the substance is not in the least degree pearly. The rostrated end exhibits a faint trace of the fold which characterizes the *Tellina*.

"Found under the same circumstances as the last, and asserted to be an inhabitant of the canals."

(585) ARCA GALACETODES, Benson.

Testa subrhomboida, tumida, subæquilateraliter antice subangulata, postice rotundata, multiradiata, radiis exilissimis aucta, rugis decussantibus; cardine mediocri, terminis exterioribus angulatis; radiis lævibus remotiusculis, incurvatis; margine lævi; epidermide fusca. Lat. 0.5, poll.

This shell belongs to the sub-division of *Arca*, which contains the English marine species *A. lactea* and the Crag fossil *A. lactanea*, Wood. (Mag. Nat. Hist. Vol. IV. N. S. P. 232, Pl. Supp. No. 13, f. 3.)

It is sufficiently distinguished from both by its tumid form; its greater length, from beak to base, in comparison with its breadth, by the shortness of its cardinal line, and its more equilateral form. As in those species, the teeth are vertical at the centre of the hinge line, and inclined or radiate at the extremities. The lozenge-shaped space between the beaks is occupied by numerous raised lines, vertical to the hinge line, which are crossed again by faint depressed lines, affording a firmer hold to the ligament and performing the same office as the angulate concentric channels or scorings in *Rissoarea*.

"Found under the same circumstances as the last, and equally asserted by the Chinese to be an inhabitant of the canals."

(586) NOVACULINA CONSTRICTA, (Lamarck.)

Testa alba, tenui, transverse oblonga, læviuscula, extremitatibus rotundatis, radio mediano subconstricta; epidermide olivaceo-flavescente, postice quasi capillis intertextis adhærentibus vestita. Lat. 2.55, Long. 0.75, poll.

*Solen constrictus*, Lamarck, Vol. 5, p. 455.

This shell, which Lamarck, has described as *Solen constrictus*, and which on the authority of Peron, he considered to be from the Chinese or Japhanès Seas appears to have been a specimen of this shell, deprived of its epidermis. The terms in which Lamarck mentions its habits and the doubt whether it belonged to China or

## CHAMPA.

Japan, may well account for his describing it as a sea-shell. The places it immediately after the British marine species *solen antiquatus*, which approaches *Novaculina* in form and in its exerted medial beaks, though it differs in the number of the teeth. From *Novaculina gangetica*, (nobis), (Gleanings in Science, Vol. 2, p. 63, 1830, and Pl. v. fig. 4, vol. 1, and Sowerby's Manual, fig. 63,) to which it bears a near resemblance, it is well distinguished by the radiate depression which runs from the apex to the base of the shell, and which bears an appearance, as if a string had been tightly tied obliquely round the closed valves when in a soft state.

*Novaculina* now numbers five species, two of them American, two Chinese, viz *constricta* and *acutidens* (Sowerby, Broderip, Zool. Jour. Vol. iv. p. 361,) and the Indian *gangetica*, the species on which the genus was originally founded. Swainson has adopted it as a sub-genus of *Solen*. Gray's *Solen novaculina* (Griff. Cuvier, vol. 12, Pl. 31, fig. 1.) appears to represent an individual of *gangetica*, of which the teeth were injured. A dwarf variety of the latter shell occurs in the mud of the aqueducts in Calcutta.

(587) "*Novaculina constricta* was picked up among a number of other shells, thrown in a heap outside the kitchen door at the house of the first civil Mandarin of Ting-hae."

With reference to the foregoing descriptions, it is interesting to observe that several forms are absent which might have been expected to occur in the latitude of Chusan. Among the land Testacea, independently of the true *Limaces*, we may notice the want of *Pupa Vertigo*, *Carychium* and *Cyclostoma* which are met with in the temperate and warmer regions of Western Asia among rocks and under stones. We miss the more ventricose forms of *Bulimus* as well as of the genus *Achatina*. *Succinea* is also wanting, but occurs abundantly farther south, at Macao. Among the fresh water genera we miss *Ampullaria*, *Neritina* and *Navicella*, and among the Acephala, the genus *Psidium*. Moradabad, December 26th. 1841.—*In Journ. Ben. As. Soc.* No 247 of 1855.

(588) CHAMBOGUM, the Tamil name of a tree, the most beautiful in appearance on the coast of Malabar; it is a very close grained wood, and throws out rather a pleasant smell when cut. It is generally found in the forests of Travancore of about eighteen inches in diameter, and from twenty to twenty-five feet long; it produces a small round fruit which the natives use medicinally.—*Edye, M. and C.*

(589) CHAMPAH Upon the summit of the lofty hills, north of Khatmandoo grows the Champah, a tree which measures in girth eleven feet at least.—*Smith's Nepal.*

(590) CHAMPA, a province on the Peninsula of Cambodia. Mr. Crawford (Embassy to Siam) informs us that Champa before its subjugation by

## CHAUNA.

the Cochinchinese was a considerable state under a chief who lived at Phaurye, lat. 11° 10' North, that in the 15th century an intercourse subsisted with the Malays and Javanese, that the Queen of the principal sovereign of Java about the middle of the 15th century was a Champa princess, that the people are called Loe or Loi in the Anam language, and that they profess a species of Hindooism resembling the worship of Buddha or Jani.

### (591) CHANK SHELL.

Sungoo, TAM.	Shenkoo, TEL. and
Sunk, DUK.	SANS.

Of these shells, which are found in great abundance on the sea coast of the southern and western parts of the Peninsula of India, the natives make rings, beads, and other ornaments. They are also sent to Bengal and neighbouring countries where they are sold, and cut into cowries (small coin).—*Ainslie's Mat. Med.* p. 143.

(592) CHARI-MARAM, the wood called ebony in England. (See Ceylon woods, &c. named Achamarum, Nuga-gaha).—*Edye, M. and C.*

(593) CHARU, the Malayala name of a jungle-wood which grows to about forty feet high, and two feet in diameter. It is used in building native vessels, particularly for planks. It is not very durable, and is of little value except for those purposes. It is cheap, and is easily procured from the banks of the rivers.—*Edye, M. and C.*

(594) CHAUNA, the name of a wood which grows in Malabar. It resembles the English beach, and is used by the natives for housework. It is not durable, nor is it remarkable for its growth, quality, or use.—*Edye, M. and C.*

(595) CHAULMOOGRA SEEDS. These seeds are furnished by the *Chaulmoogra odorata*. Rox. or *Gynocardia odorata*. The plant is referred by Lindley to the Natural order Pangiacæ which by some is considered a section of Papayaceæ. The seeds are sold in the bazaars in India at about 13s. 4d. per cwt. The tree is poisonous but the seeds yield by expression a bland fixed oil having a peculiar smell and taste. The seeds are used by the natives of India in various cutaneous diseases. For this purpose they are beaten up with ghee or clarified butter and applied to the diseased cutaneous surface. The expressed oil is prized in the treatment of leprosy in India. The surfaces of the ulcers are dressed with the oil while a six grain pill of the seed is given three times a day. The dose of the latter is gradually increased to twice the original quantity. The expressed oil is sometimes given internally in doses of 5 or 6 minims. Too large doses are apt to produce nausea and vomiting. The Chaulmoogra is also prized by the Chinese *Notes on the Chaulmoogra seeds of India by Charles Murchison, M. D., M. R. C. P.* L. p. 353.

(596) **CHIRETTA**, on the varieties of Chiretta used in India. Dr. Hugh Cleghorn, M. D. Madras Medical Service, in writing remarks that he has frequently been struck with the evident dissimilarity between bundles of Chiretta, as received through the commissariat at different stations in the Madras Presidency, and although the stalk when chewed possessed the characteristic quality of pure bitterness and exhibited the many seeded capsule, the tetragonal stem and opposite sessile exstipulate leaves by which the Gentian family is recognised, he could not help thinking that the supplies furnished on indent contained several distinct plants. The collection of native drugs brought together at the time of the Madras Exhibition of 1855 furnished him with an opportunity of testing the accuracy of his previous opinion, and it occurred to him that a short notice of two distinct plants used in southern India might not be unacceptable. The properties of the Indian species of Gentianæ with the exception of two or three of the Himalayan ones, do not seem to have been at all investigated. After a diligent search in the medical literature of India, he could find not a single notice of their therapeutic action although the remarkable property of bitterness exists in the four general *Exacum*, *Ophelia* and *Adenema*, as well as in all the indigenous species which he had met with.—*Ed. New Phil. Mag. No. 6 of April 1856.*

(597) **CHECK**. Checks fit for children's dresses and gown pieces of great variety, the quality very good, the color tastefully distributed and the dyes excellent are made in the Madras Presidency.—*M. E. J. R.*

(598) **CHENTSU**. A tribe, one of the non-Arian races of India. Vocabularies of six of these, the Kondh, Savara, Gadaba, Yerukala, and Chentsu are given at p. 39, No. of 1856, of *Beng. As. Soc. Journal*.

(599) **CHERU-PUNA** in Tamil and Malayala, which is the small leaf poon. This wood is the real mast poon, which is preferred for the masts of ships or vessels. Peon, or Puna, consists of five sorts, all of which are similar in shape and growth; the largest sort is of a light bright colour, and may be had at Mangalore, from the forests of Corumcul, in Canara, where it grows to a length of one hundred and fifty feet. At Mangalore, Mr. Edye procured a tree of this sort that would have made a foremast for the *Leander*, sixty gun-ship, in one piece, for the sum of 1,300 rupees, or £149 sterling. Poon grows in the forests of Cochin and Travancore, but it is of a very inferior quality to that before stated; one sort is named the *Karapa Puna*, which is dark poon; and *Malai Puna*, meaning the hill poon; and another sort, the *Vellai Puna*, or the white poon; this sort is small, not more than twelve or eighteen inches in diameter, and eighteen or twenty feet long. In Canara, another sort, named *Merchie*

*Puna*, grows to twenty-eight inches or three feet in diameter, and from thirty to fifty feet long; and is very much like American birch. It is generally defective and not durable; consequently it is never brought from the hills, for, when felled, it opens and splits at the top and but for many feet in length. The weight of the poon may be said to be from forty to forty-eight pounds the cubic foot; but the lightest I have met with was thirty-four and three-quarters, and the heaviest fifty pounds, the cubic foot, when dry. The leaf of this tree is small and oval, about two by one and a half inches broad, and the fruit grows in bunches; it is about the size of coffee-berries; from this the natives extract oil, which is used for various native purposes.—*Edye, M. and C.*

#### (600) CH'HUTTEE.

Ch'huttee, HIND.

A Mahomedan rite, held on the sixth or seventh day of a woman's confinement.—*Herkl.*

#### (601) CHILLAH.

Chillah, HIND.

The fortieth day after child-birth, on which a Mahomedan woman performs her purifications.—*Herkl.*

(602) **CHILLOUNEA**. The Chillounea is a singular tree of Nepal. Its upper coat is entirely composed of innumerable needle-form fibres tolerably united by a kind of gelatinous sap. The wood makes good beams and rafters, and is held in such superstitious veneration by the natives, that no house is considered secure in which more or less of the timber has not been employed.—*Smith's Nepal.*

(603) **CHINA**. The great staff of life in China is rice, which is either eaten dry, or mixed with water, so as to resemble a soup. Out of rice they make their chief intoxicating liquor, which when good is something like strong whisky, both in its colourless appearance and its smoky flavour. Other vegetables are consumed such as the sweet potato, Barbadoes millet, peas, beans, turnips, carrots, &c. Of their fruits, the orange, lichee, loquat and mangoes are much in use. Their favourite animal food is pork, the taste for which is natural. There is a maxim prevalent among them, that "a scholar does not quit his books nor a poor man his pigs." The flesh of the bullock, sheep, deer, dog, cat and horse is eaten, but compared with that of swine, it is a rarity. Fish are eaten in great abundance, either fresh, dried or salted, and they rear great quantities of ducks and various species of fowl for the table. The comprehensive principle on which Chinese diet is regulated, is to eat everything which can possibly give nourishment. The luxuries consumed by the rich consist of the edible birds nest, the bech de mer or sea slug; shark fins, fish maws, cow sinews, points of stag antlers, buffalo hides, which afford the gelatinous foods considered so restorative.

## CHROME ORE.

Amongst their delicacies also, are dishes made of the larvæ of the sphinx moth, and of a grub bred in the sugar cane.

(604) CHINNIE MARUM. Chini in Tamil, Kasawha in Malayala. This is a tree which grows to about eighteen inches in diameter, and twelve feet long; it is heavy and close grained; it produces a small berry much like pepper, which, as well as the wood, is not of much use.—*Edye, M. and C.*

(605) CHIRONIA CENTAUROIDES. Nat. ord. Gentianacæ. Nyè, Hind. This plant is found in some parts of India.

(606) CHLORINE. (Solution of). To prepare this, take Muriate of soda sixty grains, sulphuric acid two fluid drachms, red oxide of lead three hundred and fifty grains, water eight fluid ounces. For this beautiful, and in India most useful process, Dr. O'Shaughnessy was indebted to the Edinburgh Pharmacopœia. It supercedes the use of manganese, which in India can only be procured from European druggists. It is used for bleaching, also for inhalation, and for the fumigation of infected apartments.—*Beng. Phar. p. 369.*

(607) CHOUGH, the Chough, or 'Cornish Chough' as it is often called (*Fregilus graculus*), an inhabitant of the more elevated regions of the Himalaya and of all high middle Asia, is stated to have been obtained "in the vicinity of Calcutta."—*Cul. Rev.*

(608) CHOUTAL, the Malayala name of a tree that grows to about forty feet in height, and eighteen inches in diameter. It is a wood which the native coopers use in preference to the woods of the country for casks, vats, tubs, &c.—*Edye, M. and C.*

(609) CHOOTRAPHUL. The Chootraphul is a Nepaul tree, not unlike the barberry in appearance; the wood is of a strong yellow colour, but does not afford a permanent dye; the women of Nepaul use it instead of sandal for tracing the tillah on their forehead.—*Smith's Nepaul.*

(610) CHROME ORE. Very good samples of the Chromate of Iron were exhibited at the Madras Exhibition of 1859 from Salem, Vizianagarum and Bangalore, but as yet nothing has been done to turn this mineral to useful account on a large scale in India, from the want of proper appliances. The great consumption of this substance in Europe is in the manufacture of Bichromate of Potash for dyes, the chromates of Lead for painting, and chromic acid for coloring pottery, porcelain and glass. The mineral was carefully tested some years ago and a few ounces of the Bichromate of potash and the yellow and orange Chromates of Lead were made in the School of Arts Madras. The supply of Chrome Ore in Salem is said to be abundant, but the raw material will not pay the expense of freight, though the Chromates of potash and Lead might be brought into use in dyeing

## CINCHONA.

and painting if carefully manufactured in India. The Chrome ores used in England are obtained from the Shetland islands and Styria where they are abundant. The quantity required for manufacturing purposes is not very large, hence the raw ores of India could never be brought into the English market so as to prove remunerative.—*M. E. J. R.*

(611) CHRYSANTHEMUM INDICUM. Indian Chrysanthemum. Hind. Gool-daoodi. Yellow and white varieties are common.—*Gen. Med. Top. p. 206.*

(612) CHRYSOPRASE (from χρυσος golden or beautiful, and "υπασον" a leek) is a rare apple-green calcedony, which owes its colour to the presence of the metal nickel.

(613) CHURNUS, called momea, in Nepaul, from its resemblance to wax, burns with a clear bright flame.—*Smith's Nepaul.*

(614) CINCHONA. The official report of the cultivation of the Cinchona tree in Java has reached Calcutta, and is about to be translated for the use of Government. The success of this important experiment is stated to have been complete, and Java may in a few years furnish a large supply of quinine to India as well as to Europe. The cultivation had proved successful, the authority being an official statement to the Dutch Government on the subject, a translation of which was kindly put in our way.—*Englishman Newspaper, Calcutta.*

When it is recollected that Dr. Weddel discovered the Cinchona Calisaye, yielding the invaluable yellow bark of English commerce, flourishing abundantly in the Cinchona regions of Bolivia and a part of Peru, between 19° and 13° of South latitude; and that the corresponding parallels of the Eastern hemisphere include the Neilgherries, and that great chain of hills which extends from Munneepore to Cape Negrais, many of whose rocky peaks and platforms rise to an elevation of at least 5,000 feet, when, further, it is borne in mind that the Coffee, a plant nearly allied to the Cinchonacæ, is apparently indigenous to a portion of the latter range; that, as shown by Dr. Falconer, two trees very nearly allied to the true barks, the Hymenodiction excelsum and the Lucalia gratissima are native in India, the latter growing abundantly in Sylhet at the foot of the Kossyah Hills; and also when it is recollected that the rocky nature of the soils; and the hygrometric condition of the atmosphere in many of these situations appear very closely to approach those of the tracts in which the Cinchonacæ thrive best;—it can scarcely be doubted that the experiment of introducing it into India, might be tried again, with every prospect of success.

The two genera in India closely allied to Cinchona, and which were formerly described by Botanists as species of that genus are, the one Hymenodicyton, species H. excelsum (Cinchona

excelsa of Roxburgh) growing in the hilly parts of India to the size of a large tree, and yielding a bark which is very bitter and tonic, and acts as a febrifuge, although not known to yield any alkaloid like quinine. Another, *Lucalia*, yields a species, *L. gratissima* (*Cinchona gratissima* of Wailich), growing abundantly in Sylhet. It forms a small elegant tree, and is very nearly allied to *Cinchona*, but it is not known to possess any energetic medicinal properties.

One South American species, introduced within the last two years, is now growing in the Honorable Company's Botanic Garden Calcutta. It is the *Cinchona* (*Remigia*) *ferruginea*, from the dry mountains of the province of Mines in Brazil. It yields the "Quina de Serra" or Quina de Remigo, which is substituted as a febrifuge for true *Cinchona* bark in Brazil.

The species most desirable for introduction into India are,

*Cinchona Condaminea*.

*C. Mierantha*, before all others and then,

*C. Nitida*,

*C. Lancifolia*,

*C. Lucumæfolia*,

*C. Ovata*,

*C. Lanceolata*,

*C. Dubescens*.

*C. Cordifolia*,

*C. Magnifolia*.

*Indi. Anna. Medi. Science*, page 252 and 259.

(615) CINNAMON. The attention of agriculturists and others having of late been called to the cultivation of cinnamon in the straits, consequent on the favorable result of the experiments made by Mr. Ferrier at Malacca, as published in the "Singapore Free Press" of the 19th September last, the following hints and suggestions as to the mode of cultivation and preparation of the spice may not prove unacceptable to intending planters.

That the soil and climate of the straits settlements is suitable for the growth of cinnamon there can be little doubt, for it seems to be generally admitted that it has for years been grown at all three, but no advantage has been taken of the fact, simply perhaps from the circumstance of no one's knowing how to do so.

Cinnamon after the attainment of several years of age, blossoms about the month of May, the fruit ripens about the month of August,—when ripe it is of a purple color.

**Seeds.** Should it be desirable to preserve the seeds, which can be done for some months without injury, they are cleaned of the pulpy skin in which they are enclosed, in the following mode.—Keep them in a chatty or other similar vessel, for a few days, when the skin will have rotted and decomposed to such an extent as to be easily removed, put them into a bucket, pour cold water upon them, and by stirring them about the decomposed pulp will be easily washed off,

spread them out on a mat in a shed to dry, but they must not be exposed to the sun, as they will split, and thus be rendered useless. It is not necessary however that this process should be followed previous to planting, as seeds planted with the skin on them grow admirably, provided they be planted at once.

**Nursery** For the formation of a nursery, the seeds should be put into the ground at 6 inches apart, and at from 2 to 4 months growth they can be shifted into the plantation, where they ought to be planted at a distance of at least 10 feet.

For the first cutting when the tree is three years is the usual time. At first the young tree will present one or two stems for peeling, these are to be cut off at about 6 inches from the root, when the next year the number of stems may be doubled, and so on for some years. Care must be taken to bank up the young shoots, to prevent their being broken off at the root either by getting top heavy or gusts of wind, whilst all weak and small branches ought to be carefully cut off, as useless themselves, they only tend to weaken the main stem. Cinnamon for peeling ought not to be allowed to grow up to standard trees, but kept continually in the bushy state.

The proper season for cutting is when the fruit has ripened, and after a shower of rain,—for this reason, I presume, that the bark is more easily peeled, when cut the branches should not be allowed to dry, but ought to be peeled forthwith and on the spot, for if allowed to dry there is great difficulty in separating the bark from the wood, and to enable that to be done, it is sometimes requisite to beat the branch with the haft of the knife, which contuses the bark and injures the peelings. Peeling is done with a knife, by making 2, 3, or 4 incisions in the bark length-ways in such lengths as the knots of the branches will admit, and then gently easing off the bark with the same implement, care being taken not to break or cut it in any way—it is a simple process, and easily learnt. After peeling, the bark is to be scraped, which is done with the circular knife, by placing the bark on a smooth round stick, for instance a Malacca cane, and scraping it till the whole of the epidermis is taken off, it is then to be spread out on a mat to be dried, but not to be put in the sun. It will then of itself roll up, and take the shape designated quills,—it is then to be sorted into Nos. 1, 2, 3. No. 1 is distinguished by brightness of color, delicacy of flavor, and thinness of skin, and is to be found in the bark of the middle of the branch, whilst No. 2 is to be found at the upper end, and No. 3 at the lower end of the branch. When sorted, the quills are laid up in lengths of 4 feet, made up in a way similar to that in which a cigar is, viz., all the small pieces put inside the finest and longest bits of

## CINNAMON.

bark that can be got, and which are joined the one to the other, till the length of 4 feet is attained. After the quills have thus been laid up, they are exposed on a mat in the sun for a couple of days to dry. Five days are generally required from the cutting to complete the curing, till ready for packing. The quills are tied up into convenient bales, sewed up in gunny bags, with round black pepper sprinkled amongst the cinnamon, to preserve its flavor.

*Oil.* A very excellent and valuable oil can be extracted from the coarse bark of the cinnamon, one very like that of cloves can be distilled from its leaves, camphor of good quality is procured from its roots, its branches are excellent fire wood, and old timber is valuable for casks for the exportation of arrack, as it is said to impart a fine flavour to the spirit, and Ceylon arrack fetches a higher price in the European market in consequence.

J. FERRIER.

*Malacca, 27th September, 1851.*

*Cultivation.* It appears from experience that the soil of Ceylon is more favourable to the growth of Cinnamon, than to that of any other aromatic plant, and the climate of Ceylon, if at all, differs but in a very slight degree from that of the Straits. The spice if cultivated in the Straits, will it is supposed, prove superior to that of Ceylon, if one may judge from the various spices that grow there almost wild, and it would moreover yield a better return than in Ceylon. This supposition is confirmed from having seen the spice which was prepared in 1850, in Pringet, by the Honorable Resident Councillor of Malacca, and which was found to be equally as good in every respect as that grown and cultivated in the Maritime Provinces in Ceylon.

A sandy soil is that which is generally selected for cinnamon, but other soils may be chosen, also, such as a mixture of sandy with red soil, from quartz, gravel or rock, also red and dark brown soils. Such land, in a flat country, is preferable to hilly spots, upon which, however, cinnamon also grows, and even abundantly, such for instance as the hills of Ceylon which are known by the name of the "Kandyan Mountains." The soil that is rocky and stony under the surface is bad and not adapted for the cultivation of cinnamon, as the trees would neither grow fast, nor yield a remunerative return.

When a tract of land of the above description is selected, the whole of the ground should be cleared, leaving a few trees for shade, to which the labourers might return for rest and relaxation: these may be from 50 to 60 feet apart. The trees felled should be well lopped, burnt and cleared away, the stumps should be removed with the roots after which they may be allowed to remain, in order to save expence of carriage, merely by observing some degree of order in the disposition, by forming regular rows, of which the interven-

## CINNAMON.

ing spaces are planted with cinnamon. The ground being thus cleared, holes may be dug at 8 to 10 feet apart, and of one foot square; the distance from each plant will depend upon the nature of the soil, that is, the poorer the soil the nearer to each other should be the trees planted, and *vice versa*.

When this operation is over should the holes be intended for cinnamon roots, or stumps, the latter must be carefully removed with as much earth as can be carried up with them and placed in the holes, taking care not to return the earth removed originally in digging the holes, which are to be filled with the soil scraped from the surface, which has been previously burnt, exposed, and formed into manure. Should no rain have fallen after the placing of the roots in the holes the stumps should be well covered, and watered morning and evening until such time as the sprouts shoot out fresh buds, which will be in a fortnight or so from the time they were transplanted, when the watering may be discontinued. In a month, the new shoots will be 3 or 4 inches high,—this much depends upon the weather.

If the holes be intended for young plants or seedlings, the plants must be removed with boles of earth from the nurseries, and placed in the holes, taking the same care as with the stumps, both in watering and covering, in the event of its being dry weather. When the seedlings take root, the coverings should not be removed until the plants throw out a new pair of leaves from the buds, which is a sign of their having taken root.

When a plantation is formed of old stumps all the branches should be cut down within 6 inches from the ground;—this should be done with one stroke of a sharp instrument in order to avoid the splitting of the stem. From these stumps cinnamon may be cut and peeled within 18 months from the time of transplanting. Often this is done after the lapse of 12 months from the time of transplanting.

From seedlings one cannot expect to gather a crop before 2 or 3 years from the time the plants were transplanted, when there will be but one or a single tree, which when cut down as already shown 4 or 6 inches to the ground, ought to be covered with fresh earth gathered from the space between the rows, and formed in a heap round the plant. The next crop will be 3 or 4 times as much as the first, from the number of sprouts the stem will throw out, and so on every year, the crop increasing according to the number of sprouts each stem will throw out yearly from the cuttings. In the course of 7 or 8 years, the space left between the rows will only admit the peelers and others to go round the bushes to weed, clear and remove cuttings; as the branches from each bush will almost touch each other at their ends.

## CINNAMON.

It is essentially necessary to take every care not to allow any creepers or other weeds to grow, the former interfere with the growth of the bushes by entangling because it not only takes out so much of the soil feeding the cinnamon trees, but interferes with the peelers during the cutting season and prevents the branches growing up straight with a free circulation of the air. The plantation ought to be kept clean and free from weeds, the cinnamon requires no manuring, but when the plantation is weeding the bushes should be covered with the surface soil and raising the ground round the bush by making a heap of the earth, which answers well in lieu of manure. This operation must be attended to as soon as the cinnamon sticks be removed for peeling. The plantation requires weeding 3 or 4 times a year during the first 2 or 3 years, then twice a year will answer the purpose as by that time the trees will form into bushes and destroy the seeds of the weeds on the ground.

**Nursery.** The forming of a nursery is necessary, for which a space of ground say an acre, should be selected in a rich bit of soil, free from stones. Clear the whole brushwood, only leaving the large trees for shade, remove all stones, stumps and roots, dig the place well 6 or 8 inches deep, then form into long beds of 3 or 4 feet wide, put the seeds down 9 or 12 inches apart, cover them 8 or 12 inches above the ground by a platform, and water them every other day until the seeds grow up and give one pair of leaves—then leave off watering (unless great dry weather—when it ought to be continued) but not uncover until the plants grow up 6 or 8 inches high, can bear the sun, and these seedlings will be ready for transplanting after three months from the time they were sown.

The forming of nurseries is done at the close of the year before December. When this is to be done first the party commences clearing and preparing the land during the dry season which is from the beginning of December up to end of March following. April will set in with heavy rain (it is generally so in Ceylon) and will continue wet weather till the end of August and very often till September and October, and have the benefit of 4 or 5 months rain.

The cinnamon seeds are to be gathered when they are fully ripe, they must be heaped up in a shady place, to have the outside red pulp rotted, when it turns quite black, then have the seeds trampled or otherwise freed from the decomposed pulp, uninjuring the seeds, and have them well washed in water, (just as done to cherry coffee, before they are made into parchment in the white shell) and have the seeds well dried in the air, without exposing them to the sun, and then put them in on the ground prepared for their reception. If cinnamon seeds after washing be exposed to the sun even for twenty minutes, the shells will crack into two and

## CINNAMON.

destroy the seeds from growing. In washing the seeds those that float on the surface should be rejected.

There are five different sorts of cinnamon, viz:—

1st is called Panny Meeris Caruudoo.

2nd „ „ Tittha ... „

3rd „ „ Kahatte ^ ... „

4th „ „ Wallee ... „

5th „ „ Savell ... „

Of these, the first kind is the best of all: the 2nd and 3rd although inferior, are peeled likewise, the 4th and 5th are spurious.

The distinction in the cinnamon can be known both by taste, and the shape of the leaves on the tree, and an experienced “Chaliya” man will judge the quality of cinnamon by first sight.

The quality of the bark depends upon its situation in the branch, that peeled from the middle of the bush or branch, being the *most superior* or 1st sort, that taken from the upper end is the 2nd quality, while the bark removed from the base of the branch, or the thickest end, is the most inferior and called the 3rd sort.

From the cinnamon bark refused in the sorting store of all kinds, in separating the first, second and third qualities and in making up into bales for exportation, the refuse is collected, and by the chemical process, cinnamon oil is extracted, which sells very high, with an export duty of 3s. or 1½ rupees on each ounce, exclusive of the British duties payable in England for importation, which in 1851, were one shilling and three pence per ounce. No export duties exist in the Straits settlements.

From the cinnamon leaves, a liquid is extracted in the same manner, which goes by the name of “clove oil,” and is sold for a little less than cinnamon oil, with a duty I believe as on cinnamon oil.

Of the cinnamon roots camphor is made, and sells well both in Ceylon and other parts of the world by exportation.

Return of cinnamon exported from Ceylon for ten years, shewing the quantity and value for each year.

Year.	Quantity.	Value.
1841	317,919	£24,857
1842	121,145	15,207
1843	662,704	66,270
1844	1,057,841	105,784
1845	405,669	40,821
1846	401,656	40,165
1847	447,369	44,836
1848	421,687	49,168
1849	733,755	73,378
1850	644,857	64,485

**Duties.** After the monopoly was abolished by government in 1834, the dealers in cinnamon had to pay 8 shillings per lb., for every lb. exported from Ceylon. From the 1st June 1842, this duty was reduced to two shillings per lb. on

## CLEOME

the 1st and 2nd quality, and one shilling per lb. on the 3rd quality.

Upon representation of this still heavy duty on cinnamon by the Chamber of Commerce, it was again reduced from 12th September 1848 to 2d. per lb. on the 1st and 2nd quality, and 4 pence on the 3rd quality, and continues to be so.

During the existence of monopoly and *Raja-kariye* (compulsory labour) each *choliya man* (cinnamon peeler by caste and birth) was bound to supply the government store with 60 lbs., on pain of corporal punishment and hard labour, for 3 months during the year, gathering the spice either from the government plantations or private property, but since the monopoly was abolished every cinnamon peeler receives remuneration upon the quantity of cinnamon he peels on his own account for sale to the highest bidder, and with the assistance of his family, he can prepare 3 or 4 lb. of cinnamon per day during the gathering season. **TIKERY B. DUNDEWELLE**, *Malacca, August, 1851, in No. XI, Vol. V, Journal Ind. Arch. Nov. 1851.*

### (616) CIRCUMCISION.

Annual, a native of cultivated lands. It is more upright, and less ramous than another species, and from one to three feet high. This species has a considerable degree of pungency in the taste, but it is not durable on the tongue. The seeds are much used by the natives, chiefly the brahmins, in their curries, they are sold in all the bazars, at a very trifling price. *Roxburgh's Flora Indica. Vol. 3. p. 128.* Ainslie says this is a low growing plant, of the class *Tetradynamia*; and order *Siliquosa*; the small, hottish tasted seeds of which have got the name of *Nahi Kuddaghoo*, or Dog's Mustard; they are considered by the Native Practitioners as anthelmintic and carminative. In *Dukhanie* the seeds are called *Chorie ajooan*, and in Arabic *Buzrool bunge ahemur*.—*Ainslie's Materia Medica, Vol. 1, p. 92.*

(622) COAL. Deposits of Coal have been found along the Siamese Coast from Pinang to the vicinity of Junk Ceylon. In 1836, specimens of Coal were brought from Trang, one of the lower provinces of Siam, and subsequently a deposit was discovered at Tama, not Gurbie. Coal was found at Sungei-Kamuning, about sixteen miles above Trang, and at a place, also, nearly east of Pulo Mutiara or Pearl Island about 12 miles to the southward of S. Kamuning. It was also found at the Pulo Tiga island, lying off Purlis, on the coast of Keddah, but although this coal lies about thirty miles further south than the Trang coast coal, or rather S. Kamuning, Colonel Low was inclined to believe them to be of the same coal field. Another coal was found in the bay north of Tanjong Bumbong on the coast of Trang, betwixt the last place and Kamuning.

The discovery of coal in Ligor and Kedah on the west coast of the Malay Peninsula was brought to the notice of the Court of Directors in 1847. It is identical in composition, in the

## COCHIN CHINA.

proportion of volatile matter to charcoal, with some kinds of Cannel coal. Sp. Gr. 1.245,—Volatile matter, 46.746 ;—charcoal 52.071 ; Ash, 1.183=100. That found on the Southern coast of the island of Junk-Ceylon, (well known for its tin) and which occurs near the bank of a river and about two or three hundred feet from its mouth, was reported by Professor Ansted as adapted for every purpose to which coal is economically applied

	Sp. Gr.	In 100 parts.		
		Volatile matter.	Coke	Ash.
Junk Ceylon Coal	1.25	60.40	39.58	2.50
English Cannel Coal	1.27	60.00	40.00	0.30

The position indicated as a deposit of Coal, is in Lat. 7° 44' N. and Lon. 99° 15' E. the Southern point of Pulo Lontar bearing S. W. by S. Telebon S. S. E. and Tanjong Cotton N. E. by N. Some of it takes on the polish of fine jet. The Ligor specimens of this jet are the best.

Coal is found at Rettie on the South East coast of Sumatra, which bears a strong resemblance to that from Junk-Ceylon, sp. gr. 1.23,—Volatile matter 51.43. Charcoal 48.57. Ash not determined.

In Borneo, Coal is associated at *Pulo chir-min*, which is about 200 feet high, with a ferruginous sandstone, and overlaid by a mass of red sand and clay. At *Pulo kang Arang*, again, the coal is overlaid by white sand stone.—*Colonel Low, No. 3. Journ. Ind. Arch.*

(623) COCHIN CHINA. The Government of Cochin China is a pure despotism, the power of the king being absolute and without restriction. There are two classes of mandarins, the Civil and Military but for the administration of the affairs of the Government there are 6 departments or ministers who are termed Luc-bo, whose occupancy of power does not extend beyond three or four years. The laws and modes of punishment of the Cochin Chinese are nearly the same as those of China. Their language termed the "*Anamite*" is monosyllabic and evidently derived from that of China. Their written language indeed is merely borrowed in whole or in part from the Chinese, though the two languages have become so different that persons of the two nations cannot communicate either in reading or writing. Chinese however is the learned language of Cochin China with the pronunciation of the Cochin Chinese. The Anamite language from its monosyllabic character, presents but a small variety in the sound of the words, and a great number of significations, all indicated by the tone, are given to words spelled alike. The religion of the learned men is not well known, though they honour Confucius, that of the common people is the religion of Fo which they

## COCOS NUCIFERA

call Phat, but the people readily embrace Christianity and there were at least 440,000 Christians, when Dr. Le Fevre wrote in 1846.—*No. 3 Journ. Ind. Arch.*

(624) COCHINEAL. This insect was introduced into Java a few years ago, as a Government experiment, and apparently with more success in its production than in British India; for as long ago as 1844 it was exported from Batavia to the estimated value of 93,319 guilders.—*Crusford's Des. Dic. of the Indian Islands. p. 112.*

(625) COCOS NUCIFERA, Coconut tree.  
*The Tree*

Tenna marum, TAM. | Tenkoi chettoo, TEL.  
Narrel ka jhar HIND. | Kinghena, CAN.

This tree thrives well on the sea coast, its uses and produce are well known, the wood is occasionally used for reapers, &c., for which purposes it is inferior to the palmyra. In Ceylon, however, and on the Western Coast hard and durable rafters are procurable, the Cochin planks are prettily striped and of remarkable size.—*M. E. J. R.*

*The oil.*

Tenkaya nuna, TEL. | Thanga yennai, TAM.  
Narrel ka tel, HIND. | Coconut oil, ENG.

The genus Cocos, has many species, but no other of them is of so much importance to man as the Cocos nucifera. The C. butyracea a native of New Grenada and Venezuela might, however, be advantageously introduced into India. The Cocos nucifera, is found everywhere, even in uninhabited islands, in all tropical countries, and to the height of 1,000 feet above the sea though flourishing in greatest luxuriance in the vicinity of the ocean. It rises sixty to a hundred feet high, its cylindrical trunk, crowned with numerous waving, feathery leaves, forming an elegant object of intertropical scenery. It is one of the most useful of the palms and its various products are as variedly employed being fabricated into innumerable materials for domestic use and employed in commerce. It may perhaps enable an estimate to be formed of the value of this palm by furnishing the following statement of the exports, and imports from and into India of the products of the coconut palm, during the year 1850-51.

Exports from	Coco-nuts. Rs.	Shells Rs.	Kernels. Rs.	Oil. Rs.	Coir and Coir Rope. Rs.	Cand- jans. Rs.

Several varieties of the Coconut Palm are cultivated in India, but the fruit known as the double coconut of the Seychelle Islands does not belong to this. The fruit, or coconut, when fully ripe, can be hollowed and cleaned, by being filled with salt-water and buried for some time in the sand, when the albumen decays, and is washed out.

The nuts are made into goblets and cups and when mounted with silver, polished and carved, are very handsome; but for every day household use, they are made into lamps, ladles, skimmers, and spoons. The shells make good lamp-black and when reduced to charcoal and pulverised, an excellent dentifrice. It is from the husk of the coconut, that the fibres, so well known as coir, are prepared. The coconuts are used as offerings for idols.

The fruit bearing power of the coconut palm may be considerably improved by extracting toddy from the blossom shoots for the manufacture of jaggery during the first two years of its productiveness, after which it may be discontinued. The subsequent annual produce may be safely reckoned at fifty nuts per annum.

This fruit is a valuable product of the tree, as from ten to twelve large nuts, besides several small unproductive ones, may be seen on each bunch. In good situations, the fruit is gathered four or five times in the course of the year. The albuminous substance within the Kernel is used as an article of food and when dried is largely exported to other places as the "copra" of commerce, and the clear sweet liquid which it encloses when young is a very agreeable drink. It is indeed the albumen, in a liquid state. In Ceylon, house plasterers attribute an adhesive quality to this water of the green nut, and mix it with their white and other washes, in which lime forms a chief ingredient.

The shells of the green nuts, fixed on stakes, are used as illumination lamps.

The full ripe nut contains a small quantity of oily milk and is then used for making oil. Coconut milk is extracted by pressure and is used in making curries &c. It is from the husk of the coconut that the well known "Coir" khor, khair or roya of commerce is prepared.

Coconut husk, from which the fibres have not been separated, is used in the east in lieu of scrubbing brushes for the floor, and for polishing wood; brooms, mats and bags are likewise manufactured from it.

Coconut oil, becomes solid at about 70° Fahrenheit; it is one of the fixed or fatty oils, and consists of solid and fluid constituents: the latter or Oleine, being separated by pressure from the solid parts, called stearine or by others Coein, so largely used in the manufacture of the Stearic candles by Mr. Wilson of Vauxhall. The imports of coconut oil into England, was in 1853, 464,196 cwt. most of which was the pro-

duce of India, and in the year 1850-51, 649,152 gallons of the oil were exported from Malabar alone, principally to the Mauritius, Britain and Bombay.

Coconuts are made into hookahs, and Porcupine wood, is the name given in Europe to the timber of the coconut.

*Coir.* The rind or husk of the coconut is very fibrous and the fibres, when separated from the ripe nut, is the Roy or Coir or khair of commerce, now so extensively used for ropes, cables, matting, stair carpets, rugs, door matting, netting for sheep folds, brushes, hats, bonnets, coarse sail cloth, gunney, as a substitute for hair, for stuffing mattresses, cushions, couches and saddles; as a substitute for bristles for making brushes and brooms. The nut cut transversely is used for scrubbing floors and polishing furniture. It may give some idea of the value of this material to mention that in the three years, 1847-48 to 1849-50, coir and coir rope were imported into Calcutta, Madras and Bombay to the value of Rs. 8,81,537, more than the half of which was the produce of British India alone. The principal use to which the coir is put, however, is in the manufacture of cordage. There are different modes of preparing the fibre; the most common being to soak the nuts for many months in water, or to bury them in the sand of the sea shore. In the Laccadives, the nuts are cut about the tenth month. If cut before this the coir is weak, and if allowed to become quite ripe, the husk gets hard and woody. When cut the husk is separated from the nut, and thrown for about a year into soaking pits, which are merely holes in the sand, just within the influence of the salt water, or into fresh water tanks: but in the latter, as the water is not changed, it becomes foul and dark coloured, and affects the colour of the coir. If taken from the pits too early, it is difficult to free the coir from impurities, and if left in too long, the fibre is weakened, a result what is said also to occur in the fresh water steeping. At Calpentyra and the Akkara puttoo in Ceylon the natives separate the coir by burying the husks for six months along the border of the salt water lake, and they are dug out very clean, this mode being free from the offensive smell which arises from the fresh water steeping. When soaked sufficiently long it is washed and well beaten with heavy mallets, and then laid in the sun to dry. This being effected it is again well beaten, until the fibres are so separated as to allow of their being worked up like hemp, similar to which it is made up into cordage of any size, from the smallest ropes to the largest cable. It is said that it will not receive tar or tan, but this is doubtful. It is rough to handle, and has not so neat an appearance about the rigging of shipping as that made from hemp, but surpasses the latter in lightness

## COCOS NUCIFERA.

and elasticity, and even it is said durability; more so if wetted with salt water. From its elasticity it is valuable as cables enabling a ship to ride easier than with a hemp or chain cable. Also well suited for the running ropes of the higher sails; and the only thing to be guarded against is to prevent the sails being chafed by its rough fibres. The coir made from the husk of the nut, is calculated to realize nearly one-fourth of the proceeds of the oil. Forty cocoanuts are said to yield 6lb. of coir in Ceylon, but Mr. Robinson is quoted by Dr. Royle as stating that three large coast nuts will yield 1lb. of coir, measuring 22 fathoms; whereas ten small fine island nuts go to about 1lb. of coir, measuring 35 fathoms. A Mangalore kandy of 560 lbs. will thus be the produce of 5,600 nuts, and should contain about 20,000 fathoms of yarn.

Coir and coir rope is a considerable article of export from the Madras Presidency, and has been increasing of late years.

Years.	Hemp. Rs.	Coir and Coir Rope,	Total. Rs.

The value of the coir produce of a tree is calculated at from two to two and a half annas. The best Kiltan and Chetlat coir of the Laccadives is purchased by government at Rs. 20-12-7, per candy, or Rs. 23-12, per Calicut candy.

The net-like substance Peynadi, Tamul, "Jalla Mitta" Hind., at the base of the petiole, when very young, is delicate, beautifully white, and transparent; but when it attains maturity, becomes coarse and tough, and changes to a brown colour. Portions of these are everywhere used as strainers and sieves, for straining fluids, sifting arrowroot &c. and the Tahitian fisherman convert it into a garment, when fishing.

The flowers contain a powerfully astringent property, used medicinally and it is from the flower and spathes, before the flower has expanded, that the toddy or palm wine of this tree is obtained.

The wood is applied to various purposes, such as rafters, fences, shears, laths, shingles, chairs, and ladies' work-boxes, &c., but during the period of its most abundant bearing, (considered to be between ten and thirty-five years growth), the heart wood is of so soft and spongy a nature, that it is merely used for fences, water pipes, &c.

The Tahitians extract a gummy substance, called Pia-Pia, from the trunk of the tree.

Combs of a neat appearance are made of the

## COFFEE.

mid-rib of the segments of the leaves, and the mid-ribs when tied together, form brooms for the decks of ships: the unexpanded leaves are employed to form arches during festivals.

The leaves are from eighteen to twenty feet long; and when split into halves are plaited into screens, floor mats and baskets. Under the name of cadjans, they are employed to cover houses. The heart or very young leaves, called the "cabbage," is an excellent vegetable, though rarely used as such, as the tree dies on its being removed. The old dried leaves and the spathe are used as torches.

The uppermost and tender shoots of the coconut tree when boiled eat like cabbage and are much prized both by Europeans and Natives.—*Ainslie, p. 245. Seeman. M. E. J. R. Royle.*

(626) COFFEE. *Coffee planting in Ceylon, By C. R. Rigg, Esq.* The high prices of Ceylon Coffee in the home markets, and the reputed fertility of the "Pendant jewel of India," as Lankadiva has been called, induced many men to proceed thither between 1840 and 1844 and rush headlong into Coffee planting. It is amusing to call to mind how many of them made a mystery of the object we had in view, all afraid lest too many should enter into the undertaking; it was never regarded in so equivocal a light as a speculation. It was only to those intimately interested in their success that even the green, leafy covering of their views in life was exposed, whilst a peep at the golden harvest was granted exclusively to the few who warmed their toes on the same fends, when the short hours of a winter's morning still found us dilating on the El Dorado of our imaginations. The writer thus continues:—

Of the hundreds, who, between January 1841 and December 1844, arrived at the "Spicy Isle," or impowered agents to invest their money in cultivating the Arabian shrub, perhaps 90 per cent lost their all: 7 per cent more managed to pick up sufficient of the fragments of their once stately barque to build a little boat and escape from the floods which engulfed so many: 2 per cent took the hint in time and got clear off, whilst the odd one may have made a fortune.

As a body the planters of Ceylon had themselves to blame for very much of their disasters though individually most may plead that they went with the stream. An infatuation appears to have possessed them and they slumbered on, like the narcotized opium smoker, who having filled his lungs with the fumes of the pernicious drug, throws himself back on a couch, his nerves stimulated and his muscles flaccid for a time, whilst his mind wanders in fairy scenes and pictures future ease and repose. But time wears away the veil, he begins to be conscious, he feels a lightness in his chest, he awakes to the reality of his position—all his bright visions have turned to gloomy forebodings and blue-

## COFFEE.

devils, but he cannot extricate himself, he is tangled in the meshes of the toil, which he has woven round himself. Such, it must be confessed, was the diseased state of public mind in Ceylon; nothing was thought or talked of but planting, and a Scotchman, absolutely planted a field with Coffee in the height of dry season. The mania for planting in Ceylon was as great and as disastrous in its small way, as the Railway furor in England, the absurdity of which the planters saw through at once. The Governor and his Civil Servants dabbled in the speculation and scalded their fingers. High Civil and Military Officers, both of Her Majesty and the East India Company, entered into the enterprise, many of them far beyond their means. Merchants, trades-people and private individuals all took tickets in the lottery, drew blanks and when too late regretted it.

Freely the faults of our neighbours we blame.

But tax not ourselves though we practise the same.

The most extravagant estimates were published and circulated at home, bearing such good names that their correctness was never doubted. One made out that 300 acres might be planted, kept up, and all the Coffee to the end of the 5th year from commencement, be housed and cured for £ 3,040, whilst the produce during that time would sell on the estate for 35s. per cwt. or £4,230 for the whole, leaving a net balance of £11,900 profit in five years and a property worth £15,000. Such statements emanating from the sources they did, could not fail to entrap many even of the cautious and wary.

The magnitude of the "Coffee Mania" and the rapidity with which it spread may be judged of from the following figures. The quantity of hill forest available for the cultivation of Coffee, sold by the Government up to October 1846 (since which scarcely any land has been sold), was 287,390 acres. Previous to January 1841 very little land had been disposed of. Of this vast tract of private property, we find by official returns that on the 31st December 1847, there were 50,070 $\frac{3}{4}$  acres cultivated, of which 25,198 $\frac{1}{4}$  were planted previous to the 31st December 1844, and the remaining 24,872 $\frac{1}{2}$  in the three following years. The gross cost of this is said to have amounted to the enormous sum of £5,000,000 sterling.

The following is a comparative statement of the export of Coffee from Ceylon for 14 years, ending 1849: it must be borne in mind that nearly the whole of what was shipped prior to 1842 was native grown.

There were exported of Coffee from the ports of Ceylon,

When planting first came in vogue, the Kandians flocked in hundreds to the great distribution of rupees, but this source of labour was soon found to be insufficient and of too precarious a nature to be relied on, even had there been a superabundance. The Kandyan was able to live on the produce of his rice fields &c. &c. before European capital was introduced, and he has such a reverence for his patrimonial lands, that were his gain to be quadrupled, he would not abandon their culture, it was only therefore during a portion of the year that he could be induced, even by the new stimulus, money, to exert himself. Besides, working for hire is repulsive to their national feelings, and is looked upon as almost slavery. The being obliged to obey orders, and to do just what they are commanded is galling to them.

Next came the Lowlanders (Singhalese from the maritime provinces) who have a stronger love of gain, a liking for arrack and rooted propensity to gamble. In 1841, 1842 and 1843, thousands of these people were employed on estates: they generally left their homes for six months at a time and then returned with their savings, some to spend their hours in indolence and their earnings in debauchery, others to lay up their gains and profit by the profligacy of their neighbours; after a few months leisure, they revisited the estates. The sudden access of wealth amongst them soon engendered as much independence and far more insolence than were to be found in the Kandians: this source of labor which had at first poured forth so many thousands of useful members of society, became dried up, and the Lowlanders were only known in the central province, as domestics, artificers, traders and carters.

Southern India stepped forward to fill up the vacancy occasioned by the cessation from labour of the sons of the soil. So early as 1835, Tamil coolies had begun to immigrate into Ceylon. It would appear that for some years, whilst wages were low and no great demand for their services existed, Malabars, as Tamils are indiscriminately called, must have come over with the intention of settling, or at least of being a long time absent from their country; as the proportion of women and children was much greater than afterwards.

Looking at the annexed table, we find the greatest number of coolies that arrived in one

## COFFEE.

year, was in 1844, which may be accounted for thus: before the end of 1843 the Kandians had ceased to afford sources of labour, the Lowlanders were becoming independent not to be relied on, the "Mania" was raging at its height, and in the three previous years the departure of Indians had exceeded the arrivals by 14,823 souls.

Return of Arrivals at and Departures from the ports of Ceylon of Tamil Coolies, from 1841 to 1848.

During the years 1841 to 1846 the Tamil labourers must have saved or remitted to their country from £385,000 to £400,000: whilst the value of rice imported in Ceylon during the same period, chiefly from the Malabar and Coromandel Coasts, was valued at £2,116,189.

But against this pecuniary advantage, a great loss of life is to be placed, for during the eight years above enumerated, not less than 70,000 Malabar coolies are believed to have died in Ceylon. The planters have been most unjustly accused of aiding disease by neglect and harsh treatment. Such was not the case: I may safely say that medicines and professional attendance on the labourers, form no inconsiderable item in the accounts of almost every estate, not to speak of the indulgencies, pay and attention, bestowed on the sick. The Tamils leave their homes to make a little money and to return as soon as possible; when they arrive on estates they are fatigued by a long journey, performed under great privations, the rice they bring with them is barely enough to support life until they reach Kandy, the road they traverse from the coast to the mountain capital is notoriously insalubrious, the water on it is scanty and bad, and during the period alluded to there were no houses to protect the wayfarer from rain or perhaps more baneful dews. Thus fatigued and emaciated, they begin their labour either with the seeds of fever in their constitutions or at least predisposed to disease; in place of living well and renovating their strength, they hungered themselves and existed upon the veriest trash and carrion, in order to lay by the more of their earnings, thus frauding their employers and committing *felo de se* at the same time. There were a few men on most of the old estates who have lived in the same febrile atmosphere for years,

## COFFEE.

but they feed well and have very slight attacks. The Tamils were vastly overpaid for their work and their master did not get value for his money, but until some higher motive than that which now actuates the Singalese, shall stimulate them to labour for reasonable remuneration, the Indians will continue to obtain the same price for their feeble exertions. It is a disgrace and reproach to the people of the soil, that they pass the day in indolence and sloth, whilst strangers are cultivating their land, and amassing and carrying off the riches which they have only to stretch forth their hands and arrest.

The chief causes why coffee planting failed to be remunerative are traceable to two sources,—those who embarked in the speculation and the government. Want of knowledge and forethought on the one hand and culpable apathy on the other, are the prominent features which now appear to have led to the disastrous results. The knowledge which the former lacked was both local and general; they knew little or nothing of the country and less of the sources of industry and in too many instances a lamentable ignorance of the value of money was displayed; thousands of pounds being laid out, where there never should have been any hope of seeing it returned. In some districts estates were formed on the most villainous land, disintegrated quartz rock with a little black mould on the surface, which as soon as the plants were put in, was washed away by the first thunder-storm.

*Spem gregis, Ah! silice in nuda \* \* \* reliquit.*

Others were so much exposed that the violent winds destroyed in a few days, the growth of the previous nine or ten months.

The price of labour was raised to 18s. 9d. per month, for which there were only 25 working days, equalling 9d. each, a rate at which coffee planting cannot be profitable, considering the small amount of toil done by the Tamil and the high cost of transporting produce 100 miles by land. Then again, though so highly paid, the coolies were not made to do more than two-thirds of what they could have done if forced to exert themselves; for some planters were negligent in looking after them, whilst others allowed them to do much as they liked in order to give the estate a good name on the coast. Now this was great injustice to their neighbours, because the man who would have a quid for his quo, got a bad name and the Malabars would not serve him, or if they did for a short period, generally absconded at his busiest time, when he had the most need of them.

The early estimates and accounts led us to believe that the average cost for cultivation, up keeping, and housing crop during the first five years would be little over £10 per acre; practice has however been, on an average, expended during that period, and with what result? In place of having properties worth thousands of

pounds, many estates which cost from £5,000 and upwards have been abandoned as perfectly valueless, whilst others have been disposed of for one fifth of the amount expended on them.

The government was expected to have opened up the country with roads, and purchasers of land, in many districts, bought it under the belief that such would be the case, but there were not aware that to promise and to perform are very different things.

The Ambegama road, which was to connect the southern coffee districts with the highest navigable point of the Kalaneyganga, a most desirable undertaking and feasible in theory and on paper, was begun in or prior to 1842 and was not completed a few months since, though the distance is only 41 miles. It was a pet-project of the government and the engineering difficulties were small. A great "Trunk line" was commenced (at the end of 1842) at Peradenia and was to have led to some place or other, opening up the coffee estates of Hantana, Nilamby, Dellotte and Hewechetty, thickly peopled Carle of Maturatta, and the rich Ratemabatmaite of Walapana with its fifty fertile valleys, but after costing in the coolly thousands of pounds it appeared to hide its head in the forest and die, and its course beyond the first half dozen miles would be as difficult to trace as that of the Niger or Amazon. All that was done for Lower Dumbura was to build an expensive bridge over a small stream, where it was little needed, and to lay a heavy toll on it.

But on the main route from the coast to Kandy, the road by which labour, the main-spring of the island's prosperity, is admitted, not even an attempt was made to facilitate the Tamil's ingress and to preserve his health. This route passes through a part of the country almost uninhabited, where the water is bad, the air impregnated with miasm, and the face of the country covered by jungle, filled with wild beasts. If we look on the Malabar cooly as a fellow creature he surely deserves our sympathies under troubles and difficulties, and without reference to his disposition, nature impels us to help him. If we view him in a merely mercenary light, it is the duty of the government and his employer to protect and assist him, for though he comes with the selfish motive of earning all he can and taking as much as possible out of the country, yet the obligation is mutual and he could better do without the government and the planter than they without him.

Not only had the owners of estates a right to expect, if not to compel, the ruling powers to facilitate the communication between the interior and that part of the coast where immigrants land in the greatest numbers, and to afford them protection against weather, man and beast, for they had paid into the Treasury not less than £71,840 for their land, but the coolies themselves

had a strong claim on the government, on the broad principle of "what have you done for our money." A heavy customs duty (7d. per bushel) is levied on rice, and it is known that from 1841 to 1848 inclusive, there were imported into Ceylon 14,052,865 bushels of rice, by which the Colonial Exchequer received £409,960. Of this sum, I consider that fully one-third was paid by individuals living in the Kandyan country. However, to be within the narrowest limits, I will suppose that during the above period 245,000 continental labourers entered the province, and by remaining on an average of six months, each contributed 3s. to the rice revenue, we have thus an amount of £36,750 for which the local government made no direct return.

There was not any check on the public carters who conveyed the produce to the shipping port; these men could with impunity take a portion out of each bag and supply the deficiency of weight by watering the rest, thus not only thieving a part of what was entrusted to them but damaging the remainder. The manner in which this is performed is very simple: the coffee being extremely dry and having a strong natural affinity for moisture, porous vessels filled with water were disposed amongst the bags, and the damage is done by evaporation and absorption.

The life of a planter is lonely, monotonous and unintellectual. If he be determined to do his duty to the proprietor (whether himself or another owns the lands) he must be contented to renounce society, to withdraw from frequent intercourse with his countrymen and almost to give up the recluse's greatest resource, reading. He must rise before day-light and hurry to the coolies' huts, to endeavour to get them on the work field before sunrise, he must stand over and watch that they do not skulk their work, in rain or blazing heat, until 10 A. M.; he has then generally a mile to walk home to breakfast, which having swallowed he must see what the artificers have done during the morning. At noon he is again with the labourers and drives them until half past five, when he returns to his house, worn out in body and harassed in mind by the annoyances and laziness of all around him. By the time he has refreshed himself with soap and water his dinner is served, after which he may nod, half an hour, over a newspaper, and lay down his weary limbs for the night at half-past seven. Sunday is the only day he has to hold intercourse with his neighbours, to shave himself and arrange his private affairs.

Such a life is bad enough in fine weather, with plenty of clean clothes and food in the house, but is perfectly disgusting in the wet season. At such times there is a good deal of work to be done, such as planting out young trees, weeding, and often gathering the ripe fruit.

I shall now give some account of the cultiva-

tion of the Coffee plant. Its introduction to Ceylon must be of considerable antiquity, it having most probably been brought from the Red Sea direct at a very remote period. The young plant is a pretty shrub, the branches grow in pairs, alternately, those near the root extending the furthest from the stem and the others gradually shortening to the top, give a pyramidal appearance; the leaves are large and of a rich, deep green.

In offering the following remarks on this very important branch of tropical agriculture, I wish to point out what appears to me (after many years of practical attention to the subject) the best plan to follow in Ceylon. It must therefore be borne in mind that I do not write of cultivation generally but locally; nevertheless, I think that some parts of the Ceylon *modus operandi* may be introduced into other colonies with advantage.

In this culture, the first care is the selection of locality. This is of such paramount importance that if a material error be committed in choosing the land, all future economy, care and exertion will be but thrown away. The great requirements are elevation, shelter from wind, quality of soil, and proximity to a cart road.

The coffee plant will grow and reproduce itself on a level with the sea, and, at 2,000 feet above it, the trees whilst young, will have the most luxuriant appearance, come soonest into bearing and yield the greatest measurement quantity per acre, but the bean is light and of an inferior quality. At and a little below this height are extensive tracts of the richest land but they are subject to long and frequent droughts, the crops are in some seasons scarcely worth collecting and plantations formed in such lands must soon fall off. This has been demonstrated on the plains of Doonbera, where most of the estates have become comparatively worn out in eight or nine years.

The best properties are situated on the mountains, where rain is frequent and the temperature moderate. The soil is not generally quite so rich as in the valleys, but the forest being heavy and the fallen timber decaying gradually, a small though constant return is made to the land, whereas the trees cut down on low gardens are carried to the towns for firewood and other purposes.

The aromatic properties (and consequently fine flavor) of the coffee plant are best developed between 3,000 feet and 5,000 feet above the ocean. The higher it is cultivated with care, below frost, the better will be the quality of the produce. A mild climate and rarified air are highly favourable to coffee, both of which are given by elevation. The cool climate of the Kandyan hills is equally invigorating to the planter and his shrubs, both luxuriating in a temperature of from 55° to 60°, night and morning, whilst the thermometer rarely rises above 73° at noon.

In the elevations above 4,000 feet the trees do not yield a maiden crop until three years after planting out, and at four years old they are in full bearing. The wood taking long to grow is hard and firm before nature calls on it to support fruit, and it is reasonable to expect that it will remain longer in full vigour than a plant which is forced by the heat of lower situations into a rapid growth and speedy fructification, and which prevents the application of nourishment from the completion of its own body to the precocious reproduction of its species.

The appearance of "high mountain beans," is long, blue, the longitudinal seam curved, with its sides close and compact, its specific gravity is greater and its aromatic principle more abundant and finer than that produced on low lands, which I attribute to its being grown slowly in a cold climate. Though the quality on the hills is superior, the quantity is less. Seven cwt. per acre is calculated upon, whilst 10 cwt. is the average from low lands, though it is said that one of the Hunesgeria estates once returned 18 cwt. per acre.

I do not think that the difference of cost when laid down in Kandy between 50s. and 8s. (London prices) on coffee exceeds the ratio of 2 to 3, and in most instances the proportion is lower, on the latter, the weight of the produce of one acre being less, the cost of land carriage, freight, Colombo and London charges, &c. &c., are proportionably lower and the profit higher. But there are other and more cogent reasons for preferring the hills; amongst the rest, coffee is one of those articles of which, though the inferior qualities may be unsaleable in Europe, a superior sample will always meet with purchasers about its real value, as it is consumed by a class who will have it and who consequently must pay for it as a luxury. This was clearly shown in 1847 and 1848, when although "Ceylon plantation" was sold from 35s. to 50s. per cwt. as a general price, a few samples from the highest estates brought 85s. and 92s.

In selecting land it is better to choose an easterly or northern aspect, for though the morning sun falling on the dew is said to injure the plant, and the setting sun to improve its fruit, the advantage of shelter outweighs these considerations. Where land lying to the S. W. has to be opened, the manager will do well to take advantage of the natural facilities offered by the undulation of the surface, and from fields, so as to avail himself of the protection afforded by rising ground with a belt of forest trees on its summit to windward, and such fields should vary from 7 to 10 acres in extent.

The southwest monsoon not only blows with great fury in the hill region of Ceylon, but appears to exercise a blighting influence and to curl up and wither the few leaves it does not beat off the trees. After a strong gale, a field

of coffee exposed either to its direct influence or to an eddy wind, which is if possible more baneful, will be found in a great measure denuded of its leaves, the berries beaten off and the bark of the trees seriously injured round the part of the trunk where it strikes through the earth. When this is the case the best plan is to drive three stakes into the ground round the tree, and tie it lightly in such a manner that the friction and consequent excoriation may at least be avoided, cut the plant down to two feet and propagate the plantain tree for shelter. Under this management the shrubs spreading laterally will soon interlace their branches, render mutual support to each other, cover the ground and so acquire strength enough to resist the force of the wind in a great measure, and then the plantains may be eradicated, and the land if tenacious will have been improved by their growth.

The best soil is of a deep chocolate colour, friable and abounding with blocks and small pieces of stone, which in the rainy season prevent the excessive washing away of the mould, and by their obstructing evaporation in the dry weather, afford refreshing coolness and moisture to the roots of the plants; such patches of land are generally found at the bottom of the escarpments of the hills, or in elevated valleys and rarely on the slopes. Quartzose land, of which there is much, must be carefully avoided and clay is equally bad. I have seen quartz land, which looked more like sugar-candy than anything else, planted and grow tolerable trees for a year or two, but they could never screw themselves up to the fructiferous point. There is a black earth too, which has deceived some people, it has the appearance of fine rich garden mould but is in fact disintegrated quartz and mica, not having any of the good felspathic components in it. It is of no use planting in a good surface soil unless it have at least two feet depth, as the coffee tree has a long tap root.

The first work is to prepare a nursery, which must be proportioned to the extent of land to be cultivated; and situated with regard to proximity to the intended fields. The forest having been cut down, the branches and logs are rolled on one side and the earth dug up a foot deep, all the roots and stones being carefully removed; it is then laid out in beds, six feet wide, with trenches between, which serve the double duty of drains and paths. Good seed having been procured, the grains are sown six inches asunder; if the land becomes parched, it will be well to shade it with green branches and irrigate it night and morning; should a long continuance of rain follow the sowing, the seed sometimes decays in the ground. It requires from six weeks to three months, according to moisture and warmth, before it germinates, and in four months more the seedlings are ready to be transplanted.

On opening an estate the manager must look

for his best soil and fell the forest in patches of not more than 30 acres in area. Some plantations have fields of two or three hundred acres and in one instance there are one thousand acres in one clearing, but that is, to say the least, a very hazardous plan, for on such properties it is not a rare occurrence to see several acres together blasted by the wind and either permitted to run to jungle again, or dragging on a blighted, sickly existence at an enormous and profitless outlay of capital. But such are generally old properties, and to the individuals who formed them, little if any blame can be attributed; they acted to the best of their judgments but lacked local knowledge. Many of those who now boast of their better management are but profiting by the dear-bought experience of others.

When the forest is felled, the small branches must be lopped off and the larger ones thrown on them, which expedites the drying of the wood. Should there not be rain the timber may be set fire to in a month, but as showers are frequent, it is generally ten weeks before it is sufficiently dry for burning. After a good running fire, very little has to be piled in heaps and consumed, as making neat work is a useless expence, baking the land destroys a great portion of its most valuable vegetable component parts and the timber when left to decay forms excellent manure. The smaller branches which are not consumed, should be cut up and laid as much out of the way of the plants and movements of the labourers as possible, but not burned. For the information of those who have not seen a coffee garden, it bears no resemblance to an European garden. The land is generally a steep hill side with undulating surface, huge rocks protruding their crowns and enormous blocks of stone studding the whole extent. Blackened trunks of trees with their branches sprawling in all directions give the field the appearance of having once been the site of a town which is now laid in ashes, a confused heap of calcined stones and charred rafters. When cleared the ground is marked out by a line and pegs, in squares of six feet every way and at each peg a hole 18 inches cube is dug. These are filled up with surface soil, and when rain sets in the seedlings are transplanted from the nursery to them. This would give 1,210 trees per acre, but owing to the rocks, streams and paths, where plants cannot grow, the average is 1,000 per acre. There is difference of opinion as to the distance trees should be apart from each other, from experiments and observation, six feet is the best,—if they are further off, they will not cover the ground, in which case both land is lost and the weeds grow more easily,—if they are closer than six feet the plants are subject to breaking and injury, as their branches lock into each other and obstruct the workman's passage.

From the time of planting, the fields must be kept free from weeds, which may be done by

slight expence, if care be taken never to allow them to seed. Where swamps are found in a field, I should recommend their being drained as much as practicable and planted with guinea-grass or lemon grass, either of which will soon cover the ground, prevent weeds growing and spreading their seed, besides it is turning the land to account, for the former grass is excellent forage for horses and cattle, whilst the latter is the herb most used for thatching buildings, and even if there is a superabundance it would be profitable to cut it for measure. The most troublesome weeds on the hills are the Spanish needle, sow thistle and elk-plant. Ferns are also numerous. The Spanish needle seeds in five weeks and multiplies itself at least two hundred fold each seeding, so the reader may easily imagine the necessity for taking these noxious plants out in time. The low estates are subject to all these and several grasses, besides wild spinage, and worst of all Iluk-grass, which is of the *Andropogon* family, I believe *Andropogon caricosum*, if it once gets fairly rooted the expence of eradication is enormous. Weeding should be done by the hand and on no account with the hoe; the sloping surface affords sufficient facility by its steepness for the deluging torrents of rain to wash away the richest ingredients of the land, without its being unnecessarily loosened. Hoeing is only excusable when weeds have been suffered to flower, when they may be cut down to prevent their increase, but hand work must soon follow as the roots have been strengthened by having the stalks cut off, gain a firmer hold of the soil and will shoot up more vigorous stems.

The coffee tree, if allowed, attains 15 feet in height, but in Ceylon plantations they are all kept down to 8 or 3½ feet above the ground. This makes the shrub shoot out laterally and produce at least 25 per cent more than it would do if permitted to attain its natural height and to occupy more land. In topping care must be taken to cut off the uppermost pair of branches as their weight when in fruit would split the head of the stem. Nature is constantly throwing out young shoots, which try to grow upwards, but they must be carefully broken off as they are a great and useless drain on the juice of the plant. Never cut a sucker or branch off a tree when you do not wish another to come, but always break it.

From flowering to harvest is from 8 to 9 months. A field in full bloom is a beautiful sight, the clusters of white blossom contrast prettily with the deep green leaves and the whole at a distance looks as if it had been snowed on. The flower only lasts one day. If the atmosphere be dry the bloom is sometimes lost, as it will not set without moisture; mists and light drizzling rains are the most favourable weather at this time. The fruit grows on a foot stalk of

half an inch, in clusters round the joints of the lateral branches, and when of full size, but still green, resembles small olives. A month before ripening it turns yellow and through different shades to ruby red, when it is ripe, and from its likeness to our European fruit is technically called "cherry." During the later part of its growth, particularly, it requires a great deal of moisture, otherwise the bean will be shrivelled, not perfectly formed, light and of inferior quality. The climate of the hills is most beneficial when the fruit is filling and just before it ripens.

I have described what "cherry" is, we will now open it and find that it contains "pulp" in which are two seeds. They are covered by a viscous substance called "gum", and integument known as the "parchment" from its resemblance when dried to that animal product, and a pellicle named the "silver", which is very like gold beater's skin, and the grains of coffee, which are styled "beans:" sometimes there is only one bean in a cherry which takes a more rounded form and is called "peaberry." This is caused by only one of two embryos coming to maturity, whilst the other is abortive, the rudimentary form of which is always apparent.

When the fruit becomes blood red it is perfectly ripe and should be gathered. To the height of 3,000 feet the chief crop ripens in October and November, and a small second gathering is looked for in May. In the course of a few days the cherry passes from yellow to blood red and a great number of coolies must then be employed—for once ripe the sooner it is plucked the better. On very high plantations, though the heaviest gatherings are in June and December, some fruit is arriving at maturity almost all the year round; blossom, green and red berries, may frequently be seen on the same tree. This gives more trouble to the superintendent, but is better for the proprietor, who is not obliged to engage a large force of labourers when every one else wants them and when the Malabar knows his own value. Where the crop extends over eight months of the year, the facilities for curing it are much greater and the cost of transport lighter.

When the quantity of coffee is small it is usually dried as plucked from the tree and the flower is found superior to that which has been divested of its pulpy covering. But when the plantation is in full bearing, the extent of drying ground required, the length of time and the labour of moving so vast a weight, preclude the practicability of this plan. A pulping house must then be built: it should have a loft to receive the cherry and from which the machines are fed, a pulping room below where the mills are stationed, with a tank underneath. This building is all open, walls not being required.

The "pulper" is an oblong frame on four legs, furnished with a cylinder covered with cop-

## COFFEE.

per which has been perforated by a triangular punch, from the side laid on the wood, leaving three pointed asperities on the outside, like a nutmeg grater. In front of the grater is an iron bar or "chop", at a distance regulated according to the size of the bean, and a lower chop so nearly touching the copper that a sheet of letter paper may just pass through. A rotatory motion being given to the cylinder, the hopper above it being supplied with berries and a constant stream of water kept up, the teeth of the copper draw the berries against the chop and there not being space enough for them to pass between it and the cylinder, the pulp is torn off, carried between the lower chop and the barrel and passed away behind whilst the beans are thrown out in front on a sieve, under the machine. The pulped coffee falls into a cistern below and the "passed cherries," with a few stray husks, are returned to the copper.

The coffee is next thrown up together and allowed to remain heaped, until the gum is sufficiently fermented to be washed off, which is known by its feeling rough in the hand; this will take from 12 to 36 hours according to the quantity heaped together and the temperature of the air; great care must be taken not to over-heat it. Coolies must then dance amongst it for half an hour and a stream of clean water being let in and the coffee agitated by rakes or machinery, all the gum and dirt will soon be carried away. The beans which rise to the surface of the water, being inferior and imperfect must be floated off into another reservoir and separated. The store or ware house may be constructed of any shape and materials, which circumstances or fancy dictates. It may be built of brick or timber and covered with tiles, felt or corrugated iron, but the most economical stores have the walls of jungle sticks and clay, are thatched with lemongrass and have a loft or second floor in the slope of the roof, they are erected at a slight expence and answer every purpose. On some estates the pulping mills are turned by a water wheel, which is a great saving of labour at the time when it is most in demand, but on the high hills, the cost of transporting heavy iron work is so great, the wages of good artificers so high, and the difficulty and delay in repairing any accidental damage so retarding to the other operations, that hand work is likely always to predominate.

Drying platforms, like the barbaces of the West Indies, are not uncommon, especially amongst old estates; they are constructed of broken stones pounded together and glazed with a composition of mortar, fine sand, palm sugar (that from the palmyra being preferred) and bark juice, but as the cost is heavy, many planters prefer giving the ground a slope of 1 in 20, claying it and spreading matting to receive the coffee. Perhaps the best contrivance is a set of

## COFFEE.

trays on wheels, fitting into a shed, one under the other, and which can be run in and out, on a tramway as the weather suits.

If coffee get two days' sun after washing, there is not much fear of its being injured by being kept long in store, indeed at this stage it is advisable not to expose it to the direct influence of the sun for nine or ten days, as the gradual drying causes the silver to separate itself from the bean and to hang on it like a bag. Coffee slowly dried will be easily divested of all the silver, as just stated, and a clean sample insured, but however ripe the cherry may have been when gathered, if the bean is hardened quickly, a portion of the pellicle will adhere, leaving a dirty sample and the impression on the buyer that it had been plucked half ripe. I consider too, that the quality of the article is improved by slow drying or more properly speaking that less of the aromatic principle is evolved. During rain, which is generally very abundant at fruit time, the wet coffee must be spread under cover and constantly turned to prevent its heating, and even that which is partially dried should be worked over twice a day, as a very little moisture in a large heap soon causes germination to commence and gives to one end of the bean that peculiar red tinge, known as "foxy" in the London market.

Produce must be hard dried, until the grains resist the nail and are quite horny, before it is despatched to Colombo; but in the parchment, the protection against moisture which this shell affords, more than counterbalances the cost of its transport. After its arrival in the seaport no time should be lost in cleaning and shipping it, having been sunned, it is put in a circular trough and a heavy wooden wheel passed over it, until all the husks are broken; it is then fanned and agitated in a perforated cylinder, through which the small beans and broken pieces fall.

It must be packed in well-seasoned casks and shipped immediately, for if exposed to the saline damp, with which the atmosphere of a tropical shipping port is generally charged, it will soon attract so great a quantity of moisture as to turn flexible and black; — there are few simple vegetable products, dyes excepted, which owe so much to their colour as coffee does.

It is only a few years since capitalists began to turn their attention to the agricultural resources of the Kandyan country and yet the export of plantation coffee from the island during the year ending 10th October, 1850, was more than 235,000 cwts. The spur given to the villagers may be seen by comparing the last year's native export of 125,000 cwts. with the total shipments in the years 1836 to 1841, as given in the early part of this notice.

The first adventure naturally selected their lands near a government road and hill estates were not so much as dreamt of, until all the

## COFFEE.

available low lands were bought up. In one instance the enterprising but unfortunate proprietors believing it necessary to till the ground, went to work at a great expence, removed all the roots and ploughed up the land, but the result was a signal failure. Others left the largest forest trees standing for shade, but that has also been found injurious.

Ceylon is peculiarly adapted to the growth of coffee, and very good land may be found with a little care in selection. Being a mountainous island, with three sides open to a vast expanse of ocean, drought is little known; even in the driest seasons the hills attract clouds, which frequently pour down refreshing showers. The heavy mists and dense clouds which sometimes shut out the sun for days together, or rolling sluggishly along the mountain sides, are amongst the planter's best auxiliaries. The shrub luxuriates in a rarified, temperate and moist climate, and delights in frequent but not heavy rains on the slopes, where there is a good natural drainage—for any lodgement of water about its roots soon proves fatal.

Want of facilities for manuring, the attacks of vermin, the absence of a working population and state of the roads are amongst the greatest drawbacks.

One great error into which speculators fell, and in which we must now confess we showed childish ignorance, was to expect that the land was so rich as to be able to keep the plants up to one uniform point of fruitfulness for fifteen or twenty years without manure. It requires no knowledge of chemical agriculture, but only calm, unbiassed reflection to convince us that the richest mould cannot yield crop after crop for years, unless a proportionate return be made to it; to say that it can, would indeed be giving inorganic matter a self germinating principle. Many have tried decayed coffee pulp as a renovator, under the impression that by so doing they were placing in the ground what they wished to draw from it, but practice has too fully exploded the theory to leave any necessity for explaining its failing on scientific principles. At the same time it is equally certain that the coffee pulp in combination with other vegetable, animal and mineral matter, may form a valuable renovator of the soil. The skill of the chemist may be very advantageously brought to bear on this subject: he finds that the plant and its fruit are differently composed; he knows that it is more necessary to provide for the fruit than the stem which supports it; he finds that a large proportion of the analytical composition of the bean is nitrogen, which his science teaches him may be produced by certain phosphates &c. under particular circumstances; the knowledge accumulated by his own and other men's researches point out at once where salts and gases may be found and he works on a certainty. He can in a few days and at tri-

## COFFEE.

pling cost produce what the uninitiated may spend a life time and a fortune over without attaining. It is pitiable to see the manner in which the most soluble and the best portions of the soil are washed away by the rains; this is a subject which equally deserves the attention of the planter, with the manuring question.

There is an animal known as the "rat," which does much mischief by gnawing off the young branches, apparently to get at the tender pith; it is called "Daddawedda" by the Singalese, is as large as a weasel and of a greyish-black colour.

Monkeys, squirrels and the Daddawedda commit great depredations in fruit time; they are partial to the sweet pulp which they digest but evacuate the beans whole.

The devastation caused by the Coccus insects commonly called the "bug" is lamentable in the extreme; a tree attacked by this pest has the appearance of having had a bag of soot shaken over it, the leaves and much of the green fruit fall off and the plant is long ere it recovers its vigour.

Transport is a heavy item from the estate to Kandy. The produce is generally carried the greatest part of the way on pack bullocks, and from thence to Colombo cart hire frequently rises to 2s. 3d. per cwt. for coffee in the parchment. It is almost impossible for hill planters to work their own cattle, as the native drivers neglect them and often use them to their own profit, so the transit is generally effected by contracting with a Mahomedan drover. Absentees urge on their representatives that they should keep plenty of cattle for home use, but they little know the difficulty of purchasing stock and the heretofore almost impossibility of keeping them. The grass land on the hills, produces an herb quite unfit for the food of neat cattle, the native takes no interest in the white man's stock and disease is prevalent amongst them.

Beyond the growth of coffee, the productive resources of the Kandyan country are very great but who will develop them.

Nutmegs have been tried but with what result I know not, the only plantation of them was young and not in bearing when I left the colony and I have not seen any notice of it in the local papers. It is a very costly, hazardous and anxious culture—the plants require 10 or 12 years to attain their full vigour of bearing, and what changes in prices and prospects may not occur in that time. It is one of the many plants peculiar to that rich and beautiful region, the Indian Archipelago, and how it may thrive and to what extent its spice producing power may be weakened by naturalizing it in Ceylon I know not.

Cloves will probably never be tried, for they are more tenacious of their Archipelago home than even the nutmeg.

Though the cacao flourishes well in the Per-

denia gardens, it should not be attempted as an article of extensive cultivation. Great humidity is favourable to it only when it augments gradually and continues a long time without interruption. Heavy, occasional showers are very injurious to it. When the fruit in the dry season is wetted by a heavy shower it drops off. The harvest is very uncertain, besides the trees do not bear under eight or ten years, and it can be produced cheaper in its native country than in Asia.

Castor seed might be profitably grown by the natives in the same manner as they produce their coffee which requires little exertion beyond the gathering and conveying to town, and I do not see why the oil should not be made as cheaply and as good in Colombo as in Calcutta.

Fibrous plants are beginning to meet with a portion of that attention which they so richly merit, and a day may yet come when Ceylon shall export jute, sunhemp, (a substance equal to Manila hemp), and cloths equal to the finest cambrics, manufactured from the leaves of the alac and pine-apple.

The cactus and mulberry thrive well but we can scarcely look for silk or cochineal.

There is a plant but little known, yet by no means uncommon in the Kandyan province, which might be easily made to afford an article of export. I mean the Cassava, which is the real *Jatropha manihot* or tapioca plant. It does not require much care, is ripe in seven or eight months and the farinaceous substance contained in the roots is extracted by the simple process of scraping, washing and evaporation.

The very beautiful, peculiar and useful class of plants Schitamineæ might be very easily turned to good account; there are extensive tracts of land now useless, which might be made to produce arrow-root, ginger, turmeric, and cardamoms, in great abundance and of excellent quality. But to do all this neither labour nor manure must be spared. Such an undertaking could not repay a man of property and education. The labouring classes of Europeans cannot work in the tropics, at least at such elevations as the above mentioned plants thrive. The natives are too wanting in energy to embark in these new speculations. The Indians are keen traders and not given to agriculture, or are persons who come over from the coast for limited periods to earn a few rupees and return. The Eurasians are not an agricultural class and probable never will be so.

The men who could be most advantageously introduced would be Chinese. They are a people of a laborious, plodding, energetic and enterprising character, with much greater physical strength than Indians or Singhalese and constitutions better adapted to exertion in a hot climate than Europeans; if kept under due restraint they would be the best colonists. There is

no race who can turn land to better account by mere labour, unaided by science and advanced art.

Were a colony of 300 or 400 of them established in Doombura, for instance, on the present waste government lands, or on the old coffee estates, I doubt not that the most beneficial results would ensue. All that they want is a community of their countrymen and to be well supplied with such Chinese articles as they are used to. A small colony judiciously planted would cause a demand and consequent supply of those articles which are essentially necessary to make them comfortable, whilst they would furnish the Kandy and Colombo markets with merchandize at present scarcely known. If this first establishment succeeded, every season would reinforce their ranks with recruits from their native land. In addition to all their industrial habits and artistic acquirements, they have a great recommendation—that if they can make a living they will attach themselves to their adopted country. If they make fortunes they are even more bound to us, for whilst they and their property are under the protection of our laws, both are safe, whereas if they return to China both are in jeopardy. The Kandyans would intermarry with and bind them by closer ties than even the precious links of £ s. d. to the fertile isle. Their religions are in name, though not much in reality, the same, and being a money making race, able to keep women in slothful indolence and comfort, the celestials would be looked upon as eligible matches for the young girls of the neighbouring villages. I would not be misunderstood and supposed to advocate the introduction of Chinese as labourers for hire—as such they would never do any good. They must have an interest in the produce of their labour.—*The Jour. of the Indian Archipelago*, No. 111. Vol. 11, March 1852, page from 123 to 142.

(627) COLOSSOCHELYS ATLAS. A communication was made by Dr. Falconer, conveying the substance of a paper by Capt. Cantley and himself on the osteological characters and palæontological history of the *Colossochelys Atlas*, a fossil tortoise of enormous size, from the tertiary strata of the Sewalik hills in the north of India a tertiary chain apparently formed by the detritus of the Himalaya mountains.

A great number of huge fragments, derived from all parts of the skeleton except the neck and tail, were exhibited on the table, illustrative of a diagram by Mr. Scharf of the animal restored to the natural size.

The communication opened with a reference to the reptilian forms discovered in the fossil slate, among which colossal representatives have been found of all the known tribes, such as the *Iguanodon*, *Megalosaurus*, *Labyrinthodon*, &c., besides numerous forms of which no

living analogues exist, such as the *Enalosaurian* reptile, and *Pterodactyles*. No fossil *Testudinata* remarkable either for size or deviation from existing forms, have hitherto been found in the fossil state. The *Colossochelys* supplies the blank in the first respect, while it differs so little from the land-tortoises in the general construction of its osseous frame, as hardly to constitute more than a sub-genus of *Testudo*.

"The affinities with *Testudo* shown in the shell and extremities were found to hold equally good in the construction of the head, of which a comparatively small-sized specimen, inferred to have belonged to a young or half grown *Colossochelys*, was exhibited. The head of the adult to correspond with the dimensions of the shell, and according to the proportions furnished by a large *Testudo Indica*, was deduced to have been two feet long.

The generic name given by the discoverers has reference to the colossal size of the fossil (*κολλοσσος* et *χέλυς*), and the specific one to its fitting representation of the mythological tortoise that sustained the world, according to the systems of Indian cosmogony.

"*Colossochelys Atlas*.—The first fossil remains of this colossal tortoise were discovered by them in 1835 in the tertiary strata of the Sewalik Hills, or Sub-Himalayah skirting the southern foot of the great Himalayah chain. They were found associated with the remains of four extinct species of Mastodon and Elephant, species of Rhinoceros, Hippopotamus, Horse, Anoplotherium, Camel, Giraffe, Sivatherium, and a vast number of other Mammalia, including four or five species of Quadrumana. The Sewalik fauna included also a great number of reptilian forms, such as crocodiles and land and fresh water tortoises. Some of the crocodiles belong to extinct species, but others appear to be absolutely identical with species now living in the rivers of India: we allude in particular to the *Crocodylus longirostris*, from the existing forms of which we have been unable to detect any difference in heads dug out of the Sewalik Hills. The same result applies to the existing *Emys tectum*, now a common species found in all parts of India. A very perfect fossil specimen, presenting the greater part of the evidence of the dermal scutes, is undistinguishable from the living forms, not varying more from these than they do among each other. Prof. Thomas Bell, the highest living authority on the family, after a rigid examination, confirms the result at which we had arrived, that there are no characters shown by the fossil to justify its separation from the living *Emys tectum*. There are other cases which appear to yield similar results, but the evidence has not yet been sufficiently examined to justify a confident affirmation of the identity at present.

The result at which we have arrived is, that

there are fair grounds for entertaining the belief as probable that the *Colossochelys Atlas* may have lived down to an early period of the human epoch and become extinct since:—1st, from the fact that other Chelonian species and crocodiles, contemporaries of the *Colossochelys* in the Sewalik fauna, have survived; 2nd, from the indications of mythology in regard to a gigantic species of tortoise in India."—*Jour. As. Soc. Ben.* No. 247 of 1855.

(628) COMBUSTIBLE MINERALS. Of this class of minerals, in India, there occur

Diamonds at Panna in Bundelcund, Mallavilly, Golconda, Masulipatam.

Sulphur, in Cutch, Seinde, Nepal.

Petroleum, (Asphaltum, Naphtha,) in Assam, Rangoon.

Amber, in Cutch, Assam.

Coal, in Tenasserim, Burdwan, Sylhet Beerbhoom, Assam, along Nerbudda.

(629) COMMIPHORA MADAGASCARENSIS. (*Lindl. Fl. Med.* 173).

*Syn.* Amyris Commiphora, *Roxb. Fl. Ind.* ii. 244.) Balsamodendron? Commiphora, (*Wight and Arnott, Prod.* i. p. 93.

This is a native of Sylhet, Assam, and Madagascar; it blossoms in the Botanic Garden of Calcutta about February and March, but seldom ripens its seeds. It has been briefly noticed under its synonym, in Cyclopædia.

A resinous substance named *Googul*, (Hind.) *Mooql* (Arab) is met with in all the Bazzars of India. It much resembles myrrh, and is said by some good authorities to constitute the bulk of the article exported from Bengal as East Indian myrrh. Royle considers the *Googul* identical with the Bdelium of commerce, and he ingeniously traces in *Budleyoon* and *Madelkon* (the Greek sononyms of Googul), the *βελλιον* and *μαδθαλον* of Dioscorides. A tree in the Seharunpore Garden, pointed out as the Googul tree, had scaly bark exactly conformable to Roxburgh's description of his Amyris.

*Bdelium*. Dr. Ainslie, vol. i. p. 29, gives an excellent summary of all the information extant when his work was published, regarding this interesting substance. He adduces as synonyms, for it, Kookool, *Tam.* Googooloo, *Tel.* Goo-gula, *Cin.* Aflatoon, *Arab.* Mukul, *Pers.* Goo-gul, *Hind.* known as bdelium. He describes the gum resin as semi-pellucid, yellowish, or brown, inodorous and brittle, softening between the fingers, in appearance not unlike myrrh, of bitterish taste, and rather strong smell. He states however that it is all brought from Arabia and Persia, where the tree is called *Durukht-i-mukul*. In the Bazzars of India it is said that the googul "comes from the hills." (*Royle.* p. 177.)

The medicinal properties of Bdelium are exactly like those of myrrh, and as it is much cheaper, it may be preferred for dispensary practice.—*O' Shaughnessy, page 237.*

## CONCHOLOGY OF SINGAPORE.

### (630) COMPASS.

Padoman, MALAY.

The Malay Compass is divided into sixteen parts, twelve of which are multiples of the four cardinal points. For the cardinal points the different nations have native terms; but for nautical purposes, those of the Malay language are used throughout, as in the case of the nations of Celebes, the most expert native navigators of the present day.—*Crawford's Des. Dic. of the Indian Islands*, p. 116.

(631) CONCHOLOGY OF SINGAPORE, being a few remarks on Conchology and Malachology comprising brief Notices of some of the more remarkable "Testacea" in Singapore and its neighbourhood; with an appended catalogue of Singapore shells arranged in conformity with "Lamarck's system."—By William Traill, M.D.

The author writes as follows: The shells of Singapore are found in three principal localities, in the sea, in fresh water, and on the land; the sea shells as might be anticipated, are most numerous, the list of fresh water shells is scanty, as there are here no natural sheets of water, no river entirely of fresh water, nor even a running stream deserving the name of a rivulet, so that, with exception of springs, the only water that has not a brackish taint, is that which accumulates in artificial drains, some of them of considerable extent, and intersecting the country in various directions. A considerable number of shells which are commonly described as inhabiting fresh, are found here in brackish water, and several of them in places that are overflowed by the sea at high tides; indeed the only kind I have hitherto found exclusively in fresh water is a species of *Planorbis* which I shall presently describe.

The land shells of this place are not numerous so far as can be ascertained. I have not met with more than 23 species, though doubtless others might be added, were their localities more easy of access. Several kinds of *Helix* and *Cyclostoma* appear to inhabit the depths of the forest, from whence it is almost impossible to procure them, the jungle being, for the most part, guarded by an interwoven mass of brushwood and prickly shrubs; several species have only been discovered, after the ground has been cleared by burning the trees and thus disclosing the half calcined remains of the shells.

It cannot fail to strike any one who pursues the study of conchology in this neighbourhood, that there is a remarkable paucity of the larger and more gaily coloured shells, which does not seem easily accounted for; the coast is extensive and varied, and is, apparently well adapted to the habits of life of Molluscous animals, there are numerous sheltered bays and inlets, with large tracts of level sand, and in other places, shelving rocks clothed in part with a variety of *Algæ*. It may, however, be questioned whether the geological formation of the coast is such

## CONCHOLOGY OF SINGAPORE.

as favours the growth of shells; so far as I can ascertain from the perusal of such recent works as I have met with naturalists are but imperfectly acquainted with the primary formation of the calcareous coverings of these animals: it is known that the membrane which is called the mantle of the animal, secretes a fluid more or less tenaceous, which gradually hardens into the consistence of shell, and the manner in which it is deposited, layer by layer, has been minutely described by authors, yet it is not known from whence the mineral substance is derived, or what change it undergoes to convert it into the material forming shell. It appears probable, however, that soluble salts, or other combinations of lime existing in the water, are absorbed into the body of the animal, and from thence by the proper ducts conveyed to the surface for the formation and nourishment of the shell. Should this be the case it might, *cæteris paribus*, be expected that shells of the largest size would be found where calcareous rocks fringe the coast, and vice versa, here indeed an explanation of the difficulty seems at hand, for there are no rocks of a calcareous nature in this neighbourhood: on the other hand, it is difficult to account for the immense extent and rapid growth of the Corallines which line the coast for many miles, and in the elegance of their forms, and variety of their species, almost vie with our land forests.

This description of animal vegetation, if it may be so called, appears also to obtain its nourishment by absorption from the sea water; and I consider it not altogether unlikely, that this constant and active process maintained by the Corallines may interfere with the growth of shells in their immediate neighbourhood. One evident cause of the scarcity of many species, is, that the poor Malays and Chinese use most kinds of shell fish as food, and search the shores for them with such diligence, that they have caused a dearth of such as are common in less frequented parts of the coast. Among the group of small islands 30 or 40 miles south of Singapore, where a human habitation is rarely seen, the general character of the shells is similar to those of Singapore, but they are more abundant and of larger size, particularly the genera *Hippopus*, *Tridacna*, *Spondylus* and *Chama*, which, especially the two latter, are much used as food by the natives.

I had lately an opportunity of visiting these islands, and repeatedly explored the coral reefs at low water, and thereby had the means of observing the habits of some of the Testacea to great advantage; among others, the *Voluta undulata*, the inhabitant of which is spotted with blotches of bright red on a dark ground, and readily catches the eye, at a distance of some yards, as it moves like a huge snail through the coral foliage; the *Voluta melo* also

## CONCHOLOGY OF SINGAPORE.

inhabits these seas inferior to the former in the markings of the animal, but more than equal to it in the rich tints of the shells. Of the class of Conchifera numerous species covered the rocks or were firmly attached to branches of coral; in particular I may mention a species of *Chama* fantastically branched like coral, and in the brilliancy of its yellow colour more resembling a flower than a shell. In several of the shallow bays, I observed an abundance of a small species of *Meleagrina* or Mother of Pearl Oyster, few of the shells were larger than the palm of the hand, and of a dark slate colour. I am informed by those who are accustomed to trade in Mother of Pearl, that this kind never attains a large size. I was at first inclined to doubt the accuracy of the statement, as I do not find more than two described species, namely, the *M. margaritifera*, and *M. albina* which is also to be found here. What leads to the supposition of its being a distinct species is that the large kind has never been picked up here.

It is worthy of remark, that among the shells of these latitudes, in common with those of all tropical climates, it is rare to find a single species that is identical with any found in the north of Europe, and it is observable that the few such shells, that are found native here, are not of the more common kinds. On the contrary they are comparatively rare in both latitudes. The difference in the temperature of the seas does not seem sufficient to account for this disparity, nor does it seem probable that atmospheric vicissitudes would much affect creatures so independent of vital air: whether it may be owing to the want of some particular food, I am unable to determine. Of the species found in both latitudes may be mentioned *Chiton marginatus*, *Emarginula fissura*, *Fissurella graeca*, *Arca tetragona*, *Natica castanea*, and a species closely resembling *Trivia europaea*.

It has been already observed that the poorer natives have frequent recourse to shell fish as food, a few kinds however, are esteemed delicacies and are frequently exposed for sale in the market; of these may be enumerated *Arca granosa*, (the shell of which somewhat resembles our common cockle) *Corbicula regia* or *Cyrena* of Lamarck, *Gerithium lineolatum* of Gray, and *Voluta melo*, though the latter is not always procurable. Among the eatable shell fish, the Oyster must not be omitted, though it is for the most part lightly esteemed by the natives, who generally prefer such kinds as have stronger taste. A variety of Oysters may be found here but all are not eatable, two species in particular are of considerable size, and excellent flavour, though found in very different localities. The one kind is abundant at Pedro Branca, a large rock at the entrance to the China Seas, where they are exposed to rapid

## CONCHOLOGY OF SINGAPORE.

currents and stormy waves; here they are, invariably found strongly adherent to the rock by the surface of the lower valve. The other kind is procured from the mouth of the Moar river, between Malacca and Singapore. These being comparatively safe from the effects of storms and currents are never fixed to rocks but lie loose in the mud, in beds of considerable extent. Although Oysters are so numerous in both these places, it is rare to find any other species of shell in their immediate vicinity, a circumstance that has been remarked of Oyster beds in England and other places.

It must be allowed that discrimination between species and varieties among shells is extremely perplexing, the shades of difference between one species and another often appear less than between two varieties of the same species, the marks of distinction are often so modified by various causes, as difference in locality, change of food, &c., that uniformity of colour, size or even shape, when taken separately, are no safe guides, and unfortunately they are not always found combined. Blumenbach wisely observes that "no general rule can be laid down for determining the distinctness of species, as there is no particular class of characters which can serve as a criterion."

This variable tendency does not prevail in all shells, though some kinds are very liable to it, particularly the genus *Nassa*, many species of which are common here. In illustration of this property of change, I shall describe a species of *Nassa* found in the mud of salt swamps: it is in colour a dark brown or black, about an inch and a half in length, the outer whorl is smooth, those next the apex of the spire are furrowed longitudinally, and it possesses the usual generic mark of a prominent plait at the upper part of the aperture. Out of many specimens examined I have observed none to deviate from the above description. In the same localities may be found another shell quite similar to the other in form and colour, but not more than half its length, possessing however all the marks of a full grown shell, and as no shells of intermediate size are to be met with, there seems good reason to believe them two distinct species. The following instance is however more remarkable in connexion with the above. I lately found at Malacca a species of *Nassa* of a pale flesh colour, barred with brown, about a third of an inch in length, and little more than a grain in weight. In the same neighbourhood I met with another specimen, three quarters of an inch in length, and weighing between four and five grains. As in the former case, the two shells were exactly similar in shape and colour, though very different in size and weight, and as both had the marks of having attained their full size, was ready to believe that I had obtained two

new species; a further search however, put me in possession of fifteen additional specimens, similarly marked but all of them intermediate to the two first in size and weight; in fact the whole seventeen formed an almost imperceptible scale of gradation, sufficiently proving that they were so many varieties of one and the same species. I have observed several kinds of *Nassa* particularly abundant in the neighbourhood of the Fish Markets, where they may be seen in numbers feeding on dead fish and other animal food. This artificial mode of subsistence is possibly one cause of their variable form and size, as it is well known that domestic animals, and others that are more or less dependent on man of their support, are very apt to produce a progeny differing more or less from the parent stock. A good example of the propagation of an accidental variety, must be familiar to my readers in the instance of a well-known domestic animal of the feline genus, which in Singapore is rarely seen with a perfect tail. In the neighbourhood of Fish Markets may also be seen multitudes of dead shells of all sizes, some so minute as to be microscopic, and all tenanted by *Paguri* or Hermit crabs, as varied in size as the shells they inhabit, and like the *Nassa*, busily engaged in devouring fragments of dead fish, which is their principal food. I make mention of them here as a parallel instance of the effect of artificial life upon some of the lower animals, for these crabs are not, as might be supposed, one, or at most, two or three, species in different stages of growth. If an examination be made, it will be found that individuals of all sizes are laden with spawn, not excepting such as are so minute that their forms are not to be distinguished by the naked eye, it cannot be imagined that each of these is a different species, they are in fact an evident instance of the alteration of a species into an almost infinite number of varieties.

Of the various localities in which the Singapore shells are found, one remains to be mentioned, to describe which intelligibly, I must briefly advert to the general form of the island of Singapore. It consists of a cluster of low undulating hills based on an extensive plain having a uniform level surface, in some places not varying above two or three feet, in an area of several square miles. The whole of this valley ground is but little raised above the level of the sea, as is shewn by the salt water penetrating for miles into the interior of the island, and at spring tides, even overflowing cultivated fields. Over some parts of this low ground there is a layer of decomposed vegetable matter of variable depth, but for the most part the surface is sand, beneath which, at depths varying from 5 to 50 feet, there is a dark blue plastic clay abounding in shells, and these not of the kinds found in Mangrove swamps, but such as are common in open sandy bays or straits. After a careful ex-

amination, I cannot pronounce any to be different from those found in the adjacent seas; the forms of most of them are perfect, and in a few the colour is preserved, but they have for the most part lost their hardness, being readily crushed between the fingers. The kinds most abundant are as follows: *Placenta placuna*, *Strombus incisus*, *S. labiosus*, several species of *Nassa*, *Columbella*, *Trochus*, *Cerithium*, *Mitra*, *Turritella*, *Dentalium Aspergillum*, *Area*, *Venus*, *Corbula*, *Tellina* and others. I am informed by Mr. Thomson, the Government Surveyor, that wherever he has had occasion to make excavations in the low ground of Singapore, similar appearances present themselves, that in all the brick pits the clay is of the same description and also contains shells, moreover that in the Kallang valley, corals similar to existing species are to be found at the depth of six feet; add to this the fact that the growth of coral is early diminishing the depth of water in the neighbourhood, a good example of which is seen at the entrance to New Harbour where there is a small peaked island, between which and Singapore the coral has grown so rapidly that it is thought the island will in a very few years form a part of Singapore; taking therefore all these circumstances into consideration I conceive that the existence of shells in such situations may be rationally accounted for on the supposition that most of the valley ground of Singapore was originally sea, and has been altered and adapted to the use of man, chiefly, if not solely through the agency of coral.

Most of the shells in the annexed list may be found described in any work of reference on this subject. I shall therefore merely notice individually a few whose exterior forms, or the peculiar habits of their inhabitants, are not, so far as I am aware, very generally known.

The *Magilus antiquus* has lately been found north of Penang in the neighbourhood of Junk Ceylon, the natives set some value on them, and occasionally wear them as ornaments; the shell is singular and apt to be mistaken for a petrification, being dense in structure, diaphanous, and much like alabaster. It has been often figured and described by naturalists, but the animal inhabiting it is I believe unknown, unless described in some very recent publications: it is supposed to be a Gasteropod, though this is rather doubtful, as the shell is said to be generally found imbedded in coral or madreporæ: It is probable that this point might be satisfactorily settled by a careful examination of the above locality. Among other interesting discoveries lately made on that part of the coast, is a layer or stratum of grey limestone, of considerable extent, composed almost entirely of petrified shells. I have been fortunate enough to obtain a specimen for examination which contains three distinct species, apparently fresh

## CONCHOLOGY OF SINGAPORE.

water shells; two of them I have never seen recent here, but the third closely resembles a small *Melania* common here in stagnant ditches, their size, number of whorls, and general shape are the same, and they have both deep longitudinal striae or furrows; some of the shells were crystalline and amber coloured, though the material uniting them was of a uniform grey colour, both substances however were soluble in Hydrochloric acid.

Of the numerous class of shells inhabiting the interior of madrepores, wood, and stone, there is a species allied to "*Pholas*" which I cannot find described in any English work, though it seems to answer the description of the Genus *Jouannetia* of M. DesMoulins in a work entitled "*Manuel des Mollusques par M. Lander Range*" the shell is white, rather less than a musket ball, and nearly as globular in form, with a slight caudiform appendage at one end, striated obliquely and having accessory pieces, the consistence of the shell more resembles that of the bivalve of the "*Teredo*" than a *Pholas* and M. DesMoulins considers it to hold a place between these two genera. The specimens I have met with were in the interior of rolled masses of "madrapore" and were evidently old, as none contained the animal alive or dead. The "*Lima*" or the "file shell" of which several species are found in the straits, much resembles the genus "*Pecten*" or "scallop shell" which is well known to possess greater power of locomotion than most Bivalves. This power is possessed even in a greater degree by the *Lima*. When in the water its movements are graceful, the two valves being used as fins by means of which it swims with considerable rapidity guiding itself by its numerous tentacula which are frequently of an orange colour and arranged not unlike the petals of a flower, the shell is less curved than the scallop, and generally white, the valves do not entirely close.

The *Parmaphora* or Ducks bill Limpet is found here, though by no means a common shell, it is like a *Patella* flattened and elongated, the anterior edge always widely notched, apex slightly recurved, length from one to two inches, colour white; the body of the animal is much more bulky than the shell, and the mantle is so capacious that it covers the whole shell except the apex, which enables it in some degree to elude search, as it appears more like a pulpy or spongy mass than a shell; when touched, the mantle stains the hand a dark purple colour.

There is a species of *Planorbis* or shell allied to *Planorbis* found here in pools of fresh water, being the only species of Singapore shell that is found solely in fresh water; the outer whorl is little more than a quarter of an inch in diameter, aperture of the shell more diagonal than is usual in *Planorbis* so that when the animal moves on a plain surface the convex side of the

## CONCHOLOGY OF SINGAPORE.

shell is always uppermost whereas the animal of *Planorbis* is described as carrying its shell erect or with the diameter perpendicular; colour of the shell pale amber, no operculum, animal nearly black, mouth vertically cleft, no perceptible neck, (in the animal of *Planorbis*, the neck is said to be elongated) eyes at the base of two blunt tentacula in which also it differs from *Planorbis* which is commonly described and figured as having two subulate tentacula: the animal possesses in a considerable degree, the power of gliding through the water, apparently in search of food, with its shell entirely submerged and its smooth foot in close opposition with the surface of the water, locomotion being effected, by causing the flat part of the shell to act on the water in the manner of a fin, the head of the animal being at the same time, directed forward so as to regulate its movements; the animal does not occupy so much as half the shell, and the remaining space frequently contains air, which the inhabitant has the power of expelling at pleasure.

The Genus "*Natica*" of which there are several elegant species in Singapore, is known from the "*Nerita*" or "hoof shell" by being umbilicated, more rounded in form, and the interior not toothed, the shell has been also described as having no epidermis; to this rule however, there are marked exceptions, two of the species native here, having a strongly adherent epidermis.

In Swainson's Malacology there is a species figured as an extraordinary animal, much larger than the shell it is supposed to inhabit, one of the species found here presents the same appearance in a remarkable degree; and the phenomenon is caused in the following manner: the interior of the foot of the animal, is of a loose cellular texture, which it has the power of distending with water so as to be more than three times the bulk of the shell, but on the approach of danger it can instantly reject the water, assuming its natural size, and retreat into its shell closing after it the operculum which being of stony hardness, secures it from the attack of ordinary foes. This mechanism doubtless assists the progress of the animal through sand in which it frequently burrows.

The *Cerithium lineolatum* of "Gray" has been already alluded to, there are two shells of this Genus, neither of which I have seen described though I observed one of them named as above in a collection of the land and fresh water shells of Penang, made by Dr. Cantor, the shell so designated is about an inch and a half in length, thin and fragile, of a brown colour, with obscure transverse bands of a lighter hue, aperture more rounded than is usual in the Genus *Cerithium*, spire always truncated in the full grown shell, head and anterior part of the animal bright red like coral: the other species which I have more

## CONCHIOLOGY OF SINGAPORE.

particularly observed in Singapore, has rather a larger shell, thinner and more fragile than the other and of a darker colour, the animal is brown or nearly black and like the former, the spire of the full grown shell is always decollated; young specimens of the shell have perfect, sharp pointed spires, and the convoluted extremity of the animal then entirely fills the spiral part of the shell, but as the animal increases in size, its posterior extremity becomes more blunted and gradually retreats towards the anterior part of the shell, and as it successively abandons each turn of the spire, it throws out a viscid secretion which forms a hard shelly partition between its new situation and the disused extremity of the spire, which being deprived of its usual nourishment, soon becomes worn into holes and finally drops off: thus the shell when arrived at maturity has always the appearance of being imperfect. The habits of the animal are mixed and peculiar; sometimes it may be seen in a half torpid state, the operculum firmly closed suspended by a glistening thread, from the branch of a tree; when in motion it leaves behind it, a shining track like that of a snail; at the sides of an elongated proboscis are two tentacula, apparently short, blunt, and with eyes at their extremities: now as the Genus *Cerithium* is described as having the eyes at the base of the tentacula, this would appear a very remarkable deviation, and I was disposed to consider it as such until I had an opportunity of remarking the movements of the animal in water, where it is as often found as on land. When closely observed in that element, it is seen to expand two slender, pointed, tentacula of so delicate a structure that when out of the water they are lax, flaccid, and doubled under the protuberant eye, so as to be almost invisible. The shell has been found in running streams but more commonly in the brackish water of canals or ditches.

The very numerous genus of "*Cypræa*," or the "Cowry" shell is too well known to require a formal description, the largest species found here is the "*Cypræa tigris*" which is prettily spotted with black, it is frequently made into snuff boxes in England, the animals of several have been described and figured by authors. The mantle is so large as to cover all the shell, on the back of which there is often a longitudinal line which marks where its two folds meet: this membrane continually secretes an abundance of viscid fluid which lubricates the shell, and preserves the beautiful polish which has procured for them the name of porcelain shells. I shall only make particular mention of two kinds, the young or spawn of which I have been fortunate enough to obtain in their earliest stage of existence.

The "*Cypræa olivacea*" is the most abundant of the Singapore Cowries being found on most beaches under flat stones, it is of the size and

## CONCHIOLOGY OF SINGAPORE.

much the colour of an olive except that the back is generally mottled with brown and the mouth somewhat yellow; the specimen which I found with the young attached, was fixed in the usual manner, to the lower surface of a stone, on raising it there was found adhering to it, a flat circular membrane broader than the shell, transparent, and dotted with minute grey spots like grains of sand, on placing the substance in a glass of sea water, numbers of the grains dropped out of the membranous mass to the bottom of the glass and immediately assumed rapid and lively movements, some revolving in a rotatory manner, others alternately rising and sinking in the water or sporting over its surface. On a closer examination these grains were seen to be in reality shells, some hundreds in number, nearly transparent, having no perceptible columella and apparently consisting of a single coil or whorl, aperture round, breadth of the shell greater than the length, so that, when on a plain surface it rested on either end like a *Planorbis* or *Nautilus*, the animal effected these rapid movements by the alternate contraction and expansion of its foot which was broad and expanded and much larger than the shell, into which it seemed to have no power of withdrawing it.

There is another small Cowry occasionally found on the coast, resembling in colour the *C. adusta*, but not more than half the size and less cylindrical in shape: Captain Congalton, of the H. C. Steamer "Hooghly," sent me one that was lately fished up in "ten fathom" water near Sultan's Shoal to the westward of Singapore, that shell was partially imbedded in a species of sponge, on detaching it from which, I found the cavity of the spongy mass lined with the young fry of the *Cypræa*, differing however in several respects from that of the *C. olivacea*;—instead of being contained in one membranaceous envelope there were above two hundred transparent sacs not larger than grains of mustard seed and each containing about 30 shells so minute that they could not be distinguished without the aid of a microscope, at a moderate computation there could not have been less than six thousand young shells: the difference in size is remarkable, as the *Cypræa olivacea* which had the largest offspring is a much smaller shell than the one at present under consideration: in this case I had not an opportunity of studying their habits &c. as the animals were dead, having been many hours out of the water; when examined under a microscope the shape of the shell was found to resemble exactly that of the young *C. olivacea* above described.

On various parts of the coast, particularly on Coral banks, a considerable number of *Echini* may be observed, which (although Naturalists have separated them from the Testaceous Mollusca) it may not be out of place to mention here; one species in particular I cannot find to have

# CONCHIOLOGY OF SINGAPORE.

been hitherto described; the shell is spheroidal, flattened, not more than two inches in diameter and of a dark purple colour, the species are numerous, six or eight inches long, black, very slender and sharp pointed and somewhat elastic; the animal is found along the edges of Coral reefs, and moves with tolerable rapidity by means of its spines, when closely pursued it has the faculty of darting itself forward against its opponent and thereby inflicting considerable injury with its sharp spines, the points of which often break off and remain in the wound.

The foregoing remarks may in some measure suffice to shew what a wide field this country presents to those who have leisure or inclination to prosecute this branch of Natural History:

Catalogue of the shells of Singapore and its vicinity. The Genera arranged as nearly as possible in conformity with Lamarck's System.

N. B.—In addition to the Shells above enumerated there are ten or twelve kinds for which I cannot find a place among Lamarck's Genus.—*Journ. Ind. Arch. Vol. 1, No. 5. page from 227 to 241 Nov. 1847.*

## BIRMAH AND THE TENASSERIM PROVINCES.

*Notes on the distribution of some of the land and freshwater Shells of India: Part I.—By W. THEOBALD, Jun.*

Mr. Theobald remarks as follows: In the present paper it is my intention to give a sketch of the distribution of the land and fluviatile shells of certain portions of India, as far as they have been observed, in the hope that my notes may prove a not uninteresting addition to our previous knowledge of the subject, and shew by the great addition now made to the list of known species, how much yet remains to be done in this department of Natural History.

The names used are with scarcely an exception those furnished by Mr. Benson, who has described many of the new species in the *Annals and Magazine of Natural History* for 1857 though many still possess merely MSS. names, which, together with the new species described from specimens furnished by me, I have indicated in the following list, by asterisks (\*).

On my first communicating with Mr. Benson, he informed me that but twenty-three species of land shells were authentically known from the Tenasserim Provinces. Of these, four species,

# CONCHIOLOGY OF BIRMAH.

which escaped my notice, may here be mentioned to complete the list up to the present time, viz.

*Vitrina Birmanica*, Philippi.  
*Bulimus moniliferus*, Gould.  
*Cyclophorus perdix*, Sav.  
*Leptopoma Birmanum*, Pfr.

## CYCLOSTOMIDE.

### *Pterocyclos. Benson.*

- \* *P. pallatus*, B.—Akowtong (on the Irrawaddy R.) Not uncommon.
- \* *P. cetra*, B.—Maulmein and Phaiethan (on the Tenasserim R.) Not common.

### *Cyclophorus. Montfort.*

- C. aurantiacus*, Schum.—Tenasserim valley, not common.
- \* *C. Theobaldianus*, B.—Tenasserim valley, Maulmein, Thaitinio. This shell is nowhere common. In the Tenasserim valley it equals *C. aurantiacus* in size, but is easily distinguished by its more depressed form, colourless peristome, and flexuous striation. It has the greatest range of any Cyclostomatous shell of the provinces.
- \* *C. Haughtoni*, mihl.—n. s. Testa, simili *C. aurantiace*, solida nitidiuscula; carinata, superne saturate castanea; in decorticatis speciminibus, spira libris albidis zigzag variegata. Carina, catenata alternate albida et castanea. Periomphalo albido, fasciis nonnullis castaneis spiralisbus lineato. Peristomate vix pallidissime ochraceo, ore interiori caerulecente—Maulmein.

Size  $\frac{1.70 \text{ Major}}{1.35 \text{ Minor}}$  diameter in inches. This shell

I have much pleasure in naming after Captain Haughton, to whom I am indebted for some fine shells. It occurs abundantly at the "farm caves," and is at once distinguished from all other Tenasserim Cyclophori, by its parti-coloured funiculate keel, which is not the result of abrasion but is best seen in specimens covered by the epidermis.

- C. expansus*, Pfr.—Tenasserim valley. Not rare. This shell varies much in size, from  $\frac{1.70}{1.26}$  to  $\frac{0.80}{0.65}$

- \* *C. affinis*, mihl.—n. s. Testa, subglobosoturbinata, umbilicata, solidiuscula, castaneo-marmorata, haud nitida, vix carinata, peristomate reflexo, forti, expansiusculo-distorto, pallidissime flavescete, intus caerulecente  $\frac{1.60}{1.36}$  to  $\frac{1.40}{1.12}$

—Maulmein. This shell has no very marked character, unless a distortion in the peristome, one-third from its sutural margin, should prove constant. But two specimens were obtained, of which the measurements are given above.

- C. fulguratus*, Pfr.—Thaïet-mio, Rangoon, very common. This fine shell is not rare at Rangoon and becomes very abundant near Thaïet.

## CONCHOLOGY OF BIRMAH.

mio. It varies much in size and colour, some specimens are almost colourless  $\frac{1.80}{1.30}$  to  $\frac{1.03}{0.85}$

9.\* *C. cryptomphalus*, B.—Ava. Procured by Mr. Oldham, does not seem to be a plentiful species.

10.\* *C. scurra*, B.—Pegu (province).

11.\* *C. balteatus*, B.—Pegu (province).

12.\* *C. scissimargo*, B.—Pha'ethan. Not common.

13.\* *C. calyx*, B.—Akowtong, on the Irrawaddee: not common.

14.\* *C. cornu-venatorium*, Sav.—Ava. Procured by Mr. Oldham.

15.\* *C. perdis*, Sav. (Not obtained by me.)

### *Leptopoma. Pfeiffer.*

16.\* *L. aspirans*, B.—Tenasserim valley, very common.

17. *L. Birmanum*, Pfr. — (Not noticed by me.)

### *Alycaeus. Gray.*

18.\* *A. pyramidalis*, B.—Therabuin hill, near the Tenasserim river. This pretty little shell appears confined to Therabuin Hill, where it is not very common. It is of a delicate pink tint.

19.\* *A. amphora*, B.—Maulmein and Tenasserim valley. Rare.

20.\* *A. umbonalis*, B.—Akowtong. Not rare.

21.\* *A. sculptilis*, B.—Thaïet-mio. Rare.

22.\* *A. armillatus*, B.—Thaïet-mio. Rare.

### *Megalomastoma. Guilding.*

23.\* *M. gravidum*, B.—Maulmein. Very common.

24. *M. sectilabre*, Gould.—Yanglaw, on the Tenasserim. Very rare.

### *Rhaphaulus. Pfeiffer.*

25. *R. chrysalis*, Pfr.—Maulmein. Very rare.

### *Pupina. Vignard.*

26.\* *P. arula*, B.—Yanglaw, very rare. Among dead leaves.

27.\* *P. artata*, B.—Maulmein. Not uncommon, among dead leaves and rubbish at the foot of rocks. By the habitat "Maulmein" the "Farm caves" in limestone hills a few miles distant are intended.

### *Otopoma. Gray.*

28.\* *O. blennus*, B.—Maulmein. Rare.

### *Hydrocena. Parreyss.*

29.\* *H. illex*, B.—Pha'ethan. Not rare. On the bare face of limestone rocks.

30.\* *H. pyxis*, B.—Thaïet-mio. Not rare, under stones.

31.\* *H. frustrillum*, B.—Ava. Procured abundantly by Mr. Oldham.

### *Helix. L.*

1.\* *H. Oldhami*, B.—Ava. Procured by Mr. Oldham.

2.\* *H. sculpturita*, B.—Ava. What appears to be a small variety of the same shell occurs at Thaïet-mio, and nearly approaches *H. similis*, Fer. in aspect, though larger.

3.\* *H. bolus*, B.—Thaïet-mio. Very abundant at Thaïet-mio, Prome, Henzada, &c.

4.\* *H. paucillula*, B.—Thaïet-mio, where this minute helix is rare.

5.\* *H. mensula*, B.—Thaïet-mio. Rare.

6.\* *H. hariola*, B.—Thaïet-mio. Rather rare. Inhabits Acacia trees in jungle.

7.\* *H. petila*, B.—Thaïet-mio. Rare.

8.\* *H. refuga*, Gould.—Thaïet-mio and Akowtong. Not very rare.

9.\* *H. pausa*, B.—Akowtong. Not common. Found in gardens on Areca Palms, &c.

10. *H. rotatoria*, V. de Busch.—Akowtong. Very common, found in company with the last. This shell is rarely distinguishable from the Sylhet *H. tapeiria*, B. By the aid of a lens however the sculpture is found to be more ornate and flexuous, whilst in the latter it is simply striate.

11.\* *H. textrina*, B.—Henzada. Common in jungle. The adult shell has a very handsome pellucid appearance. In the rains the foot is too large for immediate retraction.

12.\* *H. molecula*, B.—Rangoon. This little species abounds on the Great Pagoda.

13. *H. achatina*, Gray.—Maulmein. Very abundant.

14.\* *H. bombax*, B.—Maulmein. Rather rare.

15. *H. honesta*, Gould.—Maulmein. Tenasserim valley. Rather common.

16. *H. Merguiensis*, Philippi.—Maulmein.

# CONCHOLOGY OF BIRMAH.

Tenasserim valley. Common. Seems a var. of the next species.

17. *H. Gabata*, Gould.—Maulmein. Mergui. Common.

18.\* *H. capessens*, B.—Maulmein. Not very rare.

19.\* *H. infrendens*, B.—Maulmein. Not very rare.

20.\* *H. Pylaica*, B.—Maulmein. Not uncommon. This curious little shell resembles the American *H. hirsuta*.

21.\* *H. catinus*, B.—Maulmein. Very rare.

22.\* *H. cassidula*, B.—Maulmein. Rare.

23. *H. delibrata*, B. (*H. procumbens*, Gould)—Maulmein. Tenasserim valley. Nowhere common. This species has a very wide range, being also found near Cherra.

24. *H. refuga* var. *dextrorsa*.—Phaiethan. This dextral var. was only met with at one spot in the Tenasserim valley, where it was not rare; it is curious that *H. refuga* does not occur in the valley, but was first seen at Akowtong.

25. *H. castra*, B.—Pija. Rare. A single specimen of this Darjiling shell was found at Pija between Tavoy and Mergui.

26.\* *H. ategia*, B.—Phaiethan. Not common.

27.\* *H. arx*, B.—Therabuin Hill. Rare. This hill has afforded many singular forms, nowhere else met with.

28.\* *H. convallata*, B.—Therabuin Hill. Rare. Another singular shell also met with near Pija on the coast between Mergui and Tavoy.

29.\* *H. biforcata*, B.—Therabuin Hill. A most singular shell, of which but one adult specimen was procured.

30.\* *H. ceryx*, B.—Phaiethan Hill. Rare.

31.\* *H. artificiosa*, B.—Phaiethan. Not rare, but nowhere else found.

32.\* *H. causia*, B.—Phaiethan. Rare.

33.\* *H. forabilis*, B.—Phaiethan. Very rare.

34.\* *H. perpaula*, B.—Phaiethan. Very rare.

35.\* *H. levicula*, B.—Phaiethan. Rare.

36.\* *H. petasus*, B.—Phaiethan. Not rare.

37.\* *H. precaria*, B.—Phaiethan. Very rare.

38. *H. Saturnia*, Gould.—Tenasserim valley. Rare.

39. *H. anceps*, Gould.—Tenasserim valley. Common.

40. *H. retrorsa*, Gould.—Tenasserim valley. Common.

41.\* *H. acerra*, B.—Mergui. Common.

42. *H. resplendens*, Philippi.—Tenasserim valley.

43. *H. Theodori*, Philippi.—Yanglaw. Very rare.

*Paludomus labiosa*. B. *Tavoy province*.  
*Paludomus stephanus* *Teria Ghat*.

## (632) CONDIMENTS GROWN IN TRAVANCORE.

### List of Condiments.

Botanical Names.	English Names.	Malayalim Synonyms.	Remarks.
<i>Areca catechu</i> , ... ..	Areca nut, ... ..	Caleepaecoo, ... ..	One of the staple products of Travancore: the nuts are cut into thin slices and prepared for exportation; the average annual amount exported is about 2,000 candies. A greater number is consumed in the country, as the tree is common in every district.
<i>Allium sativum</i> , ... ..	Garlic, ... ..	Vally poondoo, ...	
<i>Caryophyllus aromaticus</i> , ...	Cloves, ... ..	Keeramboo, ... ..	Clove trees. Succeed very well in General Cullen's garden, at an elevation about 1,800 feet. The products of these trees are excellent and may be reckoned among the finest specimens that may be seen any where.
<i>Coriandrum sativum</i> , ... ..	Coriander seed, ... ..	Kottamully, ... ..	
<i>Capsicum frutescens</i> , ... ..	Chillies, ... ..	Moolagoo vuttel, ...	
... ..	Bead Chillies, ... ..	Cantharee Molagoo	
<i>Coffea Arabica</i> , ... ..	Coffee, ... ..	Kappee, ... ..	Safflower. Of late years the exportation has fallen off. A great deal is consumed in the country.
<i>Carthamus tinctorius</i> , ... ..	Safflower, ... ..	Mungel, ... ..	
<i>Chavica Roxburghii</i> , ... ..	Long pepper <sup>Oh</sup> , ... ..	Thirpeeler, ... ..	
<i>Elettaria cardamomum</i> , ... ..	Cardamoms, ... ..	Yalum, ... ..	Plantations are in the North-East districts. The cardamoms are collected in November and December. They are only of the government monopoly, as the cultivators chiefly come from Madura and Dindigul and receive about two hundred Rs. for each candy delivered to the Circar. The average annual produce is 300 candies.
<i>Miristica moschata</i> , ... ..	Nutmeg, ... ..	Jathi-kaie, ... ..	
" ... ..	Mace, ... ..	Patheerce ... ..	Tapioca is extensively cultivated in gardens. Great care is requisite in the preparation of these roots, as they contain a poisonous principle, which is only got rid off by the application of strong heat. The poorer classes use the tapioca flour, but none is exported.
<i>Jatropha manihot</i> , ... ..	Tapioca, ... ..	Maracheence, ... ..	
<i>Laurus cinnamomum</i> , ... ..	Cinnamon, ... ..	Karoovay-putty, ...	Mustard. Cultivated in the Southern districts, but not to any great extent.
<i>Sinapis chinensis</i> , ... ..	Mustard, ... ..	Kadocoo, ... ..	
<i>Trigonella fœnum græcum</i> , ...	Fenugreek, ... ..	Venthayum, ... ..	It is largely cultivated and collected in the month of November and October: the average annual produce is about 2,000 candies.
<i>Zinziber officinalis</i> , ... ..	Dried ginger, ... ..	Sookoo, ... ..	

M. E. J. R.

(633) **COPPER ORES.** These of good quality occur in Guntoor, Nellore and Cuddapah; the samples however are small. Mineral samples of Copper are known to occur in 17 or 18 different localities of Southern India, in the forms of green carbonate and grey and liver colored ores, but the metal has never been traced to good veins or nests.

The green and liver colored oxides are said to occur in Kurnool, Cuddapah and Nellore. The specimens sent from the Copper Mountain Bellary as rich liver colored Copper ore, have been carefully tested and do not contain a trace of Copper. They are rich Iron ores (Hæmatitic).—  
M. E. J. R.

The mountainous parts of Nepaul are rich in mines of iron and copper. The produce of the former is smelted in other hills than those where the ore is found. The copper is of a very superior kind, and before the opening of a trade between England and India, was preferred for consumption in the territories of the King of Oude to that exported from Britain. Its supercession by the European produce, doubtless arose from the difficulty and expense of transportation through a mountainous tract, having no navigable rivers, and the ignorance of the Nepaulese in the arts of mineralogy and metallurgy. Lead mines, yielding also a proportion of silver, are to be found in Moukote and it is supposed that

## CRATŒVA TAPIA.

there are gold mines to the North, though as yet no traces of gold have been discovered excepting in the beds of the torrent which rush through Kachar to the eastward.—*Smith's Nepaul*.

(634) CORIANDRUM SATIVUM. Lin.

(635) CORONILLA GRANDIFLORA.

Buka, SANS.

Buka, also Augasta, BEN.

Basna, HIND. the red-

flowered variety, and

Sada Basna The white,

HIND.

Yerra avesi, TEL.

The name of the red flowered variety.

Tella avesi, TEL. The

white flowered.

A small, delicate tree from twenty to thirty feet high of only a few year's duration. It is generally found in the vicinity of villages, where the natives encourage its growth, for the sake of the leaves and tender pods which they use in their curries. It is in flower and fruit most part of the year.

The tender leaves and young legumes are much used in food, by all classes of the natives.

The tree is employed for training the *Betel* plant (*Piper Betel*) it admits the sun's beams, and the wind better than any other of its height, being thin of branches and leaves, particularly after it is more than one year old. It is of a very quick growth, which is another reason for employing it. The wood is only fit for fuel. Cattle eat the leaves and tender parts.—*Roxburgh's Flora Indica*, p. 331-2.

Natives commonly plant this about their houses at Bombay. It has large showy flowers and is of very quick growth.—*Graham (Thomson's Records of General Science)*, Vol. IV. p. 115.

(636) CORONILLA PICTA, is the Krishna rajam of Bengal, a plant highly esteemed for the beauty of its purple flowers, and the emollient qualities of its leaves. These are applied as a cataplasin to suppurating tumors.—*O'Shaughnessy*, pages 316-17.

(637) CORYPHA GEBANGA; GEBANG PALM. The *Corypha gebanga*, Blume, is a useful tree, in Java, thousands of boys and girls are employed in fabricating its leaves into baskets and bags: thatch, and broad brimmed hats are made of them; and fishing nets are woven from their fibre and ropes manufactured from their stalks.—*Seeman*

(638) CRATŒVA TAPIA. Lin. POLYANDRIA MONOGYNIA.

Smooth Cratœva tree. | Garlic Pear, ENG.

Mavilunghum, TAM. | Burua, HIND.

This is a common tree on the horublende schist rocks of Ajmeer. In May the tree is in profuse blossom and presents a splendid appearance, the flowers being blue and buff. The foliage is very ornamental, and the wood is used to make necklaces of. This hardy tree would be a great desideration in compounds.—*Genl. Med. Top.* p. 182. It grows to a very large size,

## CUCUMIS UTILISSIMUS.

and is used by the Natives for many common purposes.—*Ainslie's Mat. Med.* p. 211. Dr. Honigberger, tells us that the Cratœva Tapia grows in the gardens at Lahore, and that the fruit is said to be beneficial in that strange malady called serpent love.—p. 263 Vol. 1. p. 140.

(639) CRESSES, GARDEN. SISYMBRIUM NASTURTIUM, Lin.

Haleem, DUK. and HIND. | Tureh teyzuc, PERS.

Reshad, ARAB.

Cresson, FR.

In India, these are sometimes cultivated by Europeans and occasionally by Mahomedans. Water cresses are called in Dukhanie, Loot putiah.—*Ainslie's Mat. Med.* p. 12.

Among the dried seeds sold in Tenasserim bazars, for medicinal purposes, are the seeds of the common garden cress, *Lepidum sativum*.—*Mason*.

(640) CRINUM TOXICARIUM.

Bura-kanoor, HIND.

This is cultivated in gardens in Ajmere, and is very ornamental.—*Genl. Med. Top.* p. 188.

(641) CROTALARIA JUNCIA.

Sana also Senma, SANS.

Sun, BENG.

Chanamoo, TEL.

Henna, or Hane, CING.

Katou tandale cotte, REED.

*Mal. IX. t. 26.*

(642) CROTON VARIEGATUM. This has obtained the name of laurel, and is very commonly grown in pots at Bombay. The temporary bungalows on the Esplanade are surrounded with it to keep out the glare of the sun.—*Graham. (Thomson's Records of General Science)*, Vol. IV. p. 114

(643) CRYPTOMERIA JAPONICA succeeds admirably in China.—*Fortune's Tea districts*, page 16.

(644) CUCUMIS SATIVUS. Lin.

*The Oil.*

Kunkureike beenge ka

tail, DUK.

Vulleriverci ummay, TAM.

Oil of Cucumber seed.

This oil is used in cookery and for burning in lamps.—*Ainslie's Mat. Med.* p. 269.

(645) CUCUMIS UTILISSIMUS.

Dosray, TEL.

Gurke Ell lange, GER.

Kiza ul taail, ARAB.

Khyari badreng, PERS.

Kakree, HIND. and KASH-

MIR.

This is the Cucumber most used, as a vegetable, at Lahore, where it is met with half a yard in length, and is commonly eaten raw by the natives. The powder of the roasted seeds is described as a powerful diuretic, and serviceable in promoting the passage of sand or gravel.—(B. Disp.) *Honigberger*, Vol. 2 p. 265.

This is an annual, a native of the higher cultivated lands, but generally found in a cultivated state; the cold season is the most favorable.

This appears to me to be by far the most useful species of Cucumis that I know; when little more than half grown, they are oblong and a little downy, in this state they are pickled: when ripe they are about as large as an ostrich's egg, smooth and yellow, when cut they have much

## CURRENCY.

the flavour of the melon and will keep good for several months, if carefully gathered without being bruised and hung up; they are also in this stage eaten raw and much used in curries, by the natives.

The seeds like those of the other *Cucurbitace-ous* fruits contain much farinaceous matter blended with a large portion of mild oil; the natives dry and grind them into a meal, which they employ as an article of diet; they also express a mild oil from them, which they use in food and to burn in their lamps. Experience as well as analogy prove these seeds to be highly nourishing and well deserving of a more extensive culture than is bestowed on them at present.

The powder of the toasted seeds mixed with sugar is said to be a powerful diuretic, and serviceable in promoting the passage of sand or gravel. In Roxburgh's time, this agriculture was chiefly confined to the Guntoor Circar, where these seeds formed a considerable branch of commerce.

The fruit keeps well for several months if carefully gathered and suspended. This circumstance will render them a very excellent article to carry during long voyages.—*Roxburgh's Flora Indica*, Vol III. p.p. 721-22.

(646) CUCURBITACEÆ, the Cucumber and Melon tribe of plants, much employed as vegetable food, are said by Dr. Hunter, to abound in fibres of great length. Amongst these may be named;

(647) CIRCUBITA MAXIMA, "Squash-Gourd" Poosheenay kaya; Keeray: C. Citrullus, Petchay kaya, Watermelon, C. Onifera, Shoemay Poosheenay kaya, vegetable marrow, Cucumis usitata, Vellaree kai, Cucumber.

(648) CUMINUM CYMINUM, Var.  
Nutsiragum, TAM. | Coomunie siah, ARAB.  
Shazira, DUK. | Sajira seed. ENG.

Cumin seeds *Cuminum cyminum*, are a common article in the Pegu markets, and the plant, in Tenasserim is occasionally cultivated.—*Mason*.

(649) CURMBOLE, is the Malayala name of a wood from the forests in Canara. It grows to about twelve or eighteen inches in diameter, and from fifteen to thirty feet high; it is used by the natives for house-work, and is considered a useful and durable wood.—*Eclje, M. and C.*

(650) CURRENCY. The Currency of India is in the form of rupees, annas, and pice. The rupee is a silver coin, weighing three drams or a tola of 180 grains, and its rate of exchange varies about 2 shillings. It is current all over British India, on the coast line of the Southern Shores of Persia, Turkish Arabia, Arabia and Egypt, Arracan, Pegu, and Tenasserim, and Southwards towards the Mauritius.

The dollar is current from Singapore, through the Archipelago of Asia, in Borneo, Celebes, China, Cochin China, Java, Malay Peninsula, Moluccas, Sumatra, &c.

## CYORNIS BANYUMAS.

(651) CUTLERY. The rude and simple implements and tools, which ordinarily supply the wants of the natives of India, the little requirement for cutting instruments as articles for domestic use, and the cheap and abundant imports of the several articles included in this class, all tend most materially to depress the local manufacture; yet Salem and Trichinopoly afford abundant evidence of the skill with which this description of manufacture can be carried on. At the Madras Exhibition of 1855, the knives exhibited (or more strictly Daggers) from the Northern Division were excellent both as to the great excellence displayed in the workmanship, and as to the beauty and delicacy of the damasked surfaces between the highly polished and keen edges of the blade. They exhibited in a high degree the proficiency of the operatives in that part of the Madras Presidency.

Of the articles of cutlery exhibited by Arnachellum Achary, a well known Cutler at Salem, as regards manufacture, these articles may probably compete with those of Europe, though the prices are considered comparatively high, and the spear heads by the same maker were neatly executed and finished far superior to articles of this description ordinarily obtainable in this country.

The articles sent to the Exhibition from Austin, a cutler of Trichinopoly, although exhibiting considerable skill in manufacture, were inferior in workmanship to those from Salem. They are however much more moderately priced. The silver ornamental handled knives especially, are considered cheap and very good specimens of an art peculiarly Indian.—*M.E.J.R.*

(652) CUTTLE FISH BONE.  
Kadalnoora, TAM. | Sorupenka, TEL.

(653) CYCAS CIRCINALIS.  
Kabong, MALAY.

(654) CYCAS. There is a very ornamental species of cycas in the Karen forests resembling a low palm, but which has never yet been introduced around European seats.—*Mason*.

(655) CYNOMETRA.—(*The Mein-ga*, Bur.) is a small tree and makes good small posts, &c., but is chiefly used for fuel. It is abundant in the lower provinces, but grows in the upper when planted, which is sometimes done for fuel.—*Malcolm's Travels in South Eastern Asia*. V. 1. p. 191.

(656) CYORNIS BANYUMAS. In the beginning of April 1856 an author procured a fresh specimen (from the vicinity of Calcutta) of Cyornis banyumas, (Horsfield) a well known Javanese bird, only once known to have been procured before in India—viz. by Mr. Jerdon in the Nilgeris, his specimen being also now in the Bengal Society's collection. The Calcutta specimen is a young male, that had just assumed the plumage of maturity but still retaining some of the first or nestling wing coverts.—*Cal. Rev.*

## DALBERGIA.

(657) DADUGA TREE. NAUCLEA CORDIFOLIA.—*Roxb.*

Daduga, TEL.

Daduga is the Telugoo name of a large tree common in the mountainous parts of the Coromandel coast. The wood is extremely beautiful resembling that of the Box tree but lighter.—*Ainslie's Mat. Med.* p. 213.

(658) DAE JUNNAEE.

Dae junnaee, HIND.

An Accouchense.

(659) DÆMIA EXTENSA. OOTRUM FIBRE. is a promising substitute for fax. The plant grows in the Madras Presidency.

(660) DAH. The Tartar dah is made use of, not only as a sword in war, but also in peace for felling trees or cutting up firewood; consequently the friction on the handle is very great. Notwithstanding, the gum which fastens it adheres for years, except on the edge or end of the handle, where the wood itself becomes less or more worn.—*Bonyuge, America*, page 158.

(661) DALBERGIA HIRSUTA: COROMANDEL OR CALAMANDER WOOD. This is a Ceylon tree of great size, the wood having a dingy ground, and sometimes running into white streaks. It is used in cabinet work, like zebra and rose wood, to which it has some resemblance.—*Faulkner*. Tredgold mentions that the figure is between that of rose-wood and zebra-wood; the colour of the ground is usually of a red hazel brown, described also as chocolate brown, with black stripes and marks. It is said to be so hard as almost to require grinding rather than cutting, this is not exactly true, as the veneer saws cut it without particular difficulty: it is a very handsome furniture wood and turns well; it is considered to be a variety of ebony. Mr. Laird says there are three varieties of Coromandel; the Calamander or Coromandel, which is the darkest, and that most commonly seen in England, the Calamberri, which is lighter coloured and striped, and the Omander, the ground of which is as light as English yew, but of a redder cast, with a few slight veins and marks of darker tints. He says, the wood is scarce and almost or quite limited to Ceylon; that it grows between the clefts of rocks, this renders it difficult to extract the roots, which are the most beautiful parts of the trees. The Calamander wood tree is *Diospyros hirsuta*, and Kadum Berry is *C. Ebenaster*, according to Moore's Catalogue of Ceylon Plants, and therefore of the same genus as the true Ebony.—*Holtzapffel*.

(662) DALBERGIA? *Species*; LANCEWOOD OF MAULMAIN. There is a tree found all over

## DAMMER.

the Provinces which yields a wood that the residents at Maulmain sometimes call lance-wood. The Karens make bows of it, but prefer *Cassia fistula*. Mason never met with the tree in flower, but thinks it a species of Dalbergia, though it may possibly be a Cassia.

(663) DALBERGIA LATIFOLIA? This furnishes one of the Black woods of Tenasserim. Under the Burman name of yendaik, the wood of two different trees is sometimes seen; one a species of ebony, and the other a leguminous tree which, according to the descriptions of the Karens, is a species of Dalbergia, and the wood resembles the black wood of Hindustan.—*Mason*.

(664) DALBERGIA SISSOO. Sissoo is one of the most valuable of the timber-trees of India, and with the saul, is more extensively employed than any other in north-west India. The ship-builders in Bengal select it for their crooked timbers and knees; it is remarkably strong, its colour is a light greyish brown, with darker coloured veins. "In structure it somewhat resembles the finer species of teak, but it is tougher and more elastic." There are two kinds used respectively in Bengal and Bombay, the latter is much darker in colour. The Indian black rose-wood, (*Dalbergia latifolia*), is a superior species of sissoo from the Malabar coast.

(665) DAMMER. Country Rosin or Dammer.

Coongilim, TAM.

Googilum, TEL.

Raul, DUK. and HIND.

Dammer batoo, MALAY.

Chloroxylon Dupada, Buch. Ainslie says, that of the substance usually termed Dammer by the English in India, there are three sorts to be met with in the bazars called, in Tamool, vullay Coongillium, carpoo Coongillium, and noray Coongillium; in other words white, black, and coarse Dammer. It much resembles the rosin obtained from the pine both in appearance and natural qualities and would seem to be common in many Asiatic countries, being found in great abundance in Sumatra, and in Java, on several of the Sooloo islands and in the Malayan peninsula. There are no doubt different kinds of it, some of which may be the produce of a species of pinus. But what is usually exposed for sale in the lower provinces of Hindoostan, is got amongst the mountains which separate Travancore from the Madras district. Dr. Buchanan first bestowed upon the tree the scientific appellation of *Chloroxylon dupada*, an account of which may be seen in his Journey through Mysore, Canara and Malabar. It is not known whether this tree bears any resemblance to that which produces Dammer on Amboyna. The reader may find a minute description of the last mentioned by

## DAMMER.

referring to Rumphius Tom. 2nd, Lib. 3rd, cap. 9th. I shall only further observe that the Tamool name of the Indian Dammer tree is chaducula. The Malayalam appellation is payana. The black and white both grow in the district of Coimbatore at a short distance from the town i. e. about 15 miles at a place called Motaman-spettaimulay.—*Ainslie*.

*Dammer* in India supplies the place of pitch and rosin, and in the Tenasserim Provinces is the product of three different genera, belonging to the wood oil tree family—the *shorea*, the *hopea*, and the *dipterocarpus*.—*Mason*.

*Dammer*, Pwai-ngyet, *Burm.*, is found in the bazars throughout Pegu. It is yielded by the *Shorea robusta* or the Saul-tree of India, which occurs plentifully in the Forests on the Shan side of the Sitang, east of Toungho, and also, but to less extent, in the forests of the Prome district. An observer had not found however that the dammer is obtained from these forests, as none of the trees appear to have been perforated for it, so that the supplies of this article are probably brought down to Pegu from forests beyond the frontier.—*McClelland*.

*Dummar* of Bengal is the Resin of *Shorea robusta*—*Ben. Phar.* 204.

*Dammar*, *White*, occurs in fragments of variable size, marked with reddish streaks, transparent, amber-like, brittle, with brilliant fracture, very inflammable, inodorous, and tasteless. This resin flows from the *Pinus dammara*, which grows on the lofty mountains of Amboyna. It hangs from the branches, and resembles stalactites, the pieces being sometimes as large as the hand, and 4 to 8 inches long; some pieces are like *animi* resin. The dammar of the Bengal bazars is usually the produce of the *Shorea robusta*.—*O'Shaughnessy*, p. 617.

### *Dammers of the Northern and Eastern Districts.*

Saul tree dammer. (*Shorea robusta* and other species). The *Vatica tumbagaia* grows also to a limited extent on the West coast, but yields little if any of the dammer collected there.

Occurs in sticks much resembling in shape the black dammer but differing widely in colour and consistency.

In color it varies from a light yellow to a dark brown. The two colours being very frequently found in the same lump and giving it the appearance of having a regular "grain" visible and differs from the white Dammer of the western coast in its inferior hardness, opacity and its peculiar form, and from the black dammer in its color.

An intelligent native correspondent writing from Gopalpore says, There are extensive tracts of Googulam (*Vatica*) jungles in Goomsur and Cuttack provinces. The Khoonds and Woodias living in and near these jungles, wound trees in several places. The resin is used and is collected

## DARJELING IN SIKKIM.

when sufficiently solid. The Dammer collected from the decayed parts of the tree is of a dark color: the tree is called Guggilam in Telugu and tala gotso in Urya. The Khoonds and Myras make the leaves into the plates from which they eat their food and also roll up tobacco in them to smoke like a cheroot. In time of famine the above tribes live on broth made from the fruit of this tree.

(666) DAMASONIUM INDICUM. See MACASSAR.

(667) DAPHNE CANNABINA, Lourc. Wall. in As. Res. xiii p. 385 c tab: Sikkim, Nepal, Kemaon &c. 5,000 to 9,000 feet elevation. It is from this shrub that the Nepal paper is derived. The bark is boiled in a metallic pot, with oak ashes, which are highly alkaline. The softened bark is then pounded with a mallet in a stone mortar, till reduced to a pulp like dough. This pulp is churned with water into a very thin paste, until it loses all trace of fibre, and will diffuse and settle smoothly. In this state it is poured into a coarse sieve placed over a frame, with a cloth bottom floating on water. The sieve stops the coarse pieces, allows the fine emulsion to pass through, and then by agitation this is smoothly deposited over the cloth. Removing the frame, the water filters away and the pulp dries rapidly by placing the frame before a fire.

The paper is subsequently polished by friction, with a shell or piece of hard wood, sheets have been made many yards square: it may be purchased at Katmandhu for 17 annas sicca for 3 seers. Bricks of the pulp are sold from 8 to 10 annas for 3 seers. The greater part of the paper is made by cis-Himalayan Bhotecahs, east of the Kali river. The manufacture seems to have been introduced from China, about 500 years ago.—*O'Shaughnessy*, p. 531.

(668) DARJELING IN SIKKIM. Sikkim, in which Darjeling is situated, from no mountains intervening directly between it and the sea, is fully exposed to the moist south winds bringing up vapour from the bay of Bengal. These, striking against the outer portion of the Sikkim range, deposit their moisture as rain, and suspend it as mists, clouding the sun for nearly the entire year. As Dr. Hooker says, "Sikkim is hence the dampest region of the whole Himalaya."

These moist winds, which give the damp character to the climate, also contribute chiefly to render the temperature equable. During the day, the moisture laden atmosphere precludes the entrance of the sun's rays to the deep and wet valleys, and the same cause acting by night, prevents terrestrial radiation going on to any extent. Nor is this dampness of the climate confined to the rainy season alone; in the rest of the year, the heavy moist air of Bengal is attracted by the rarified atmosphere of the

mountains of Sikkim, and still blows as a moist southerly wind; while the other parts of India are under the influence of the dry north-west monsoon of the winter season.

Darjeeling, at the height of 7,430 feet above the sea, has a mean annual temperature of 50° Fah. and a remarkably equable climate, the difference between the hottest and coldest months being 22°. Allowing one degree of mean temperature for every degree of latitude north of Calcutta, whose mean annual temperature, according to the latest accounts is 78° (Humboldt gives 82°), and one degree for every 300 feet of ascent, up to a certain altitude, we have the following scale of mean annual temperature for the various heights. Of course they are theoretical, and must vary according to the northern or southern exposure, and the clearing of ground from forest, &c. still they approximate nearly the truth.

Feet.	Mean Annual Temp. Fah.	Feet.	Mean Annual Temp. Fah.
600	72°	3600	62°
1200	70°	4200	60°
1800	68°	4800	58°
2400	66°	5400	56°
3000	64°	6000	54°

The mean temperature of the Cinchona forests is from 59° to 65°; according to this table then the region of the Sikkim Himalaya, where a climate much resembling this is found, will be between 2,400 and 4,800 feet, but 500 feet or more may be allowed both above and below those limits. The botany of these portions of the Himalaya, near Darjeeling, is peculiarly interesting. In the plains below, the usual features of a tropical vegetation are observed, especially in the Terais or bands of jungle which skirts the base of the mountains, where however forms from the high land begin to appear. About 2,000 feet of elevation forests of gigantic trees of Magnolia, Cedrela, subtropical Oaks, mingled with Acanthaceæ, Melastomaceæ, &c., occur here. Dr. Hooker says, "the gullies are choked with vegetation, and bridged by fallen trees, whose trunks are richly clothed with Dendrobium Pierardi, and other Epiphytical Orchids, with pendulous Lycopodia, and many Ferns, Hoya, Scitamineæ, and similar types of the hottest and dampest climates." Convolvuli and Vixies are very common, and those rope-like plants, which form a remarkable feature in the forests of the Andes, are here observed in great abundance, throwing their cable-like stems from branch to branch; they belong chiefly to the genera Bauhinia and Robinia, among the Leguminosæ. The adversity of this aspect of the Flora is increased by scandent trumpet flowered Bignonia-

ceæ, and slender Araliaceæ (Ivies) and Dioscoreas nearly allied to the Smilaceneæ, Peppers, Wild Plantains and many species of Bamboo are common, the latter a useful article to the ingenious Lepchas. There is no climbing Bamboo among them analogous to the Chisnea scandens, the climbing Bamboo of Humboldt and Roupelaud, its place is however supplied by climbing Palms of the Genera Calamus and Plectocomia, which are found in this Zone of the Sikkim Flora, along with the Phoenix acaulis, a variety of Date Palm. The other Palms of the Sikkim mountains are Wallichia oblongifolia, Areca gracilis, Caryota urens, and Licuala pellata. Here too grows the tree fern, Alsophila gigantea, extending from 2,000 to in some cases 6,500 feet of elevation on the mountains near Darjeeling, and probably indicating here, as its congener in the Andes does, the upper limits to which the cultivation of Cinchona might be carried with success. To these may be added the Cinchona gratissima and C. Pinceana of Wallich, now made by some botanists a separate Genus, under the name of Luculia, true natives of these mountains, whose forests are enlivened by the gorgeous colors of their flowers. Above Darjeeling, Oaks and Chesnuts occur abundantly, with Rhododendrons, and the English Yew; pines, however, from the humidity of the atmosphere, are rare on the outer range, English fruits, grains and potatoes are cultivated near Darjeeling; and, in the valleys below, many varieties of rice, with Indian corn. The geological structure of the mountains of Sikkim is very uniform, the rocks being principally varieties of micaceous shale and gneiss. The soil is generally formed by the disintegration of these rocks, and is covered in some places with vegetable mould.—*Indi. Anna. Medi. Science*, page 264.

(669) DAVALLIA. Davallia is an elegant fern characterised by the fructifications being "in roundish separate spots, near the margin," and is very plentiful in the neighbourhood of Maulmain. —*Mason*.

(670) DAWUT OR EXORCISM, practised by the Mahomedans in India to command the presence of genii and demons,—for the protection from evil, casting out of devils, to create enmities, friendships or love between people, to destroy or injure enemies, detecting crimes. These are effected by philters, puleetals or lamp charms, smoke charms, amulets.—*Herkl*.

(671) DAY. Mahomedans in India reckon part of a day for the whole; thus what they mean by three days, is the day on which an event happens and the two following. The Mahomedans reckon the sidereal day, in their time, from sunset to sunset, differing thus from the European civil day, midnight to midnight, or solar day, midday to midday.

## DEYRA DOON.

(672) *DECASCHISTA CROTONIFOLIA*, appears to yield a good fibre.

(673) DEYRA DOON, is situated in latitude  $30^{\circ}18'$  north, and in longitude  $78^{\circ}$  east; it is about 60 miles in length from east to west, and 16 miles broad at its widest part. It is bounded on the south by the Sewalick range of hills, and on the north by the Himalayas proper, which are here nearly 8,000 feet above the level of the sea. On the west it is open to the river Jumna, and on the east to the Ganges, the distance between these rivers being about 60 miles."

"In the centre of this flat valley the Koolagirta plantation has been formed. Eight acres were under cultivation in 1847. There were 300 acres planted with tea in 1851 and about 90 more taken in and ready, for many thousands of young Tea plants lately raised from seeds in the plantation.

Mr. Fortune (in 1851) had the same objections to its site as to that of the Anoo and Kooasur Tea Plantations, in the Bheem Tal.

*Guddowli Tea plantation* near Paorie is situated in the province of Eastern Gurhwal, in latitude  $30^{\circ}8'$  north and in longitude  $78^{\circ}45'$  east. It consists of a large tract of terraced land, extending from the bottom of a valley or ravine to more than 1000 feet up the sides of the mountain. Its lowest portion is about 4,300 feet, and its highest 5,300 feet, about the level of the sea; the surrounding mountains appear to be from 7,000 to 8,000 feet high. The plantation has not been measured, but there are, apparently, fully one hundred acres under cultivation. In 1851, there were about 500,000 plants, about 3,400 of which were planted in 1844 and were then in full bearing; the greater portion of the others were much younger, having been planted out only one, two, or three years.

*Hawulbaugh plantation or tea farm* is situated on the banks of the river Kosilla, about six miles north-west from Almorah, the capital of Kumaon. It is about 4,500 feet above the level of the sea. The land is of an undulating character, consisting of gentle slopes and terraces, and reminded Mr. Fortune of some of the best tea-districts in China. Indeed, the hills themselves, in this part of the Himalayas, are very much like those of China, being barren near their summit and fertile on their lower sides. In 1851 thirty-four acres of land were under tea-cultivation here including the adjoining farm of Chullar. Some of the plants appeared to have been planted in 1844; but, as at Paorie, the greater number are only from one to three years old.

The first of these is at a place named Lohba, which is situated in eastern Gurhwal, about fifty miles to the westward of Almorah, and is at an elevation of 5,000 feet above the level of the sea. It is one of the most beautiful spots in this part of the Himalayas.

## DHUNCHEE.

In 1851 a Zemindarge Tea plantation was at *Kutoor*. This is the name of a large district thirty or forty miles northward from Almorah, in the centre of which the old town or village of Byznath stands. It is a fine undulating country consisting of wide valleys, gentle slopes, and little hills, while the whole is intersected by numerous streams.

*The Bhurtpoor Tea Plantation*, in the Bhem Tal in 1851, covered about four and a half acres of terraced land on the hill-side, a little to the eastward of those last noticed. The soil is composed of a light loam, much mixed with small pieces of clay-slate and trap or greenstone of which the adjacent rocks are composed.

*The Russia Tea Plantation*, also in the Bhem Tal in 1851 extended over seventy-five acres, and was formed on sloping land.—*Fortune's Report*, page 383.

(674) DEEN.

Deen, ABAB.

Applied to Mahomedanism, the term Muzhab, relating to the sectarian parts of the Deen.—*Herk*.

(675) DEVEDAH, is the Portuguese, Tamil, and Malayala name of a wood, known to Europeans by that of Cedar of Libanus, or Spanish cedar. This tree is to be found from Cape Comorin, in the south of Malabar, to the north part of Canara. It grows to a large size, from eighteen inches to two feet and a half in diameter, and from thirty to forty feet high. This may be considered a good wood, and might be found useful with the heavy woods in ship-building. The texture of some trees is hard, and might be converted into good plank. It is much used by the natives for house-work and furniture. It is imported into Ceylon, and to the coast of Coromandel, from Pegu and Rangoon, and named Chittagong wood. I need not enter into any further detail of its qualities, as cedar is a common and well-known wood to all Europeans. There is also the Vela Devedah, or white cedar, which grows in the forests of Cochin and Travancore. It may be had in great quantities, and is said to be useful and durable. I know it to be a tough wood for boards, and planks for boats and vessels, for which purpose it is generally used, as well as for house-work. It grows to about two feet in diameter, and from thirty to thirty-five feet high: its grain resembles the red cedar, but it is closer grained and heavier.—*Edye, Mal. and Can.*

(676) DIHOBIES EARTH, is found at Poodoo cottah, Hyderabad, Bellary and Mysore.—*Cat. M. E. of 1857*.

(677) DHUNCHEE; Dhunicha, or Dhunsha. *Sesbania aculeata*; Persoon: is a fibre in high esteem among the natives of Bengal. It seems to be the same as *Aeschynomene cannabina* of Konig; and the *S. Cochinchinensis* from China, and called *Juganti* in Bengal. The plant is hardy,

## DIALS.

growing rapidly from six to ten feet high ; and is considered an ameliorating crop. About thirty pounds of seed is allowed to the acre. It may be sown in poor, low, wet soil, without preparation. The price of Dhunicha in the interior is about Rs. 1-8 per maund. The fibres are from six to seven feet long : but unless cut at a very early period, they are coarser and more harsh than hemp. In Bengal, the fishermen make drag-ropes for their nets, on account of its strength and durability in water. It was valued in England at £35, and would probably always fetch £30 to £35. It is an excellent fibre for common chord and twine purposes and certainly superior to Jute in strength and durability.

*Dhanchi* fibre of Bengal *Sesbania cannabina*, is found wild, but is cultivated in northern India, on account of the fibres of its bark, which are coarse, but more durable than some other substitutes for hemp, especially when exposed to wet, and are therefore employed for the drag ropes and other cordage about fishing nets. The *Sesbania* is a genus of plants of the natural order of Leguminosæ and derives its name from the Arabic name of a species which is indigenous in Egypt ; viz : *S. Egyptiaca* ; this occurs also in India, and is a small but elegant tree : its wood is employed for making the best charcoal, for gun-powder.

(678) *DATURA FASTUOSA* AND *METEL*, &c. Dhatura (white) Kanak (black), Kanak bij (the seed) The seed only used by the natives eaten as a stimulant or given as a narcotic in medicine, or with the intention of robbing or murdering the individual who has taken it ; in the latter case it is given in sweetmeats. The natives do not smoke the plant ; the greatest benefit is however derived from smoking the whole plant in asthma as an antispasmodic and anodyne in other affections of the natives.—*Gen. Med. Top. p. 133.*

(679) DIALS.

### THE FLOWER DIAL.

"T was a lovely thought to mark the hours,  
As they floated in light away,  
By the opening and the folding flowers,  
That laugh to the summer's day.  
Thus had each moment its own rich hue,  
And its graceful cup and bell,  
In whose coloured vase might sleep the dew,  
Like a pearl in an ocean shell.  
To such sweet signs might the time have flowed,  
In a golden current on,  
Ere from the garden, man's first abode,  
The glorious guests were gone.  
So might the days have been brightly told,  
Those days of song and dream,  
When shepherds gathered their flocks of old,  
By the blue Arcadian streams.  
So in those isles of delight, that rest  
Far off in a breezeless main,  
Which many a bark, with a weary guest,  
Has sought, but still in vain,  
Yet is not life, in its real flight,

## DIPTEROCARPEÆ.

Marked thus, even thus, on earth,  
By the closing of one hopes delight,  
And another's gentle birth ?  
Oh ! let us live so that flower by flower,  
Shutting in turn, may leave  
A lingering still for the sunset hour,  
A charm for the shaded eve.

*Mrs. Hemans.*

(680) *DIOSPYROS CORDIFOLIA*. EBENACEÆ, *Roxb. c. 50, Ill. 148.*

Vuckana marum, TAM.

A hard heavy wood, colour brown, said to be very strong, but difficult to work.

(681) *DIOSPYROS EBENASTER*. KÆNIG : EBONY.

Toomoka chava, TEL.  
Abnoos, HIND.  
Atcha wood, ENG.

Kakataetee or Autcha  
marum, TAM.

This very heavy black wood grows in abundance in the Ganjam Circars, and in Berar ; also in Ceylon, where it is called Nuga gaha.—*Ainslie's Mat. Med. p. 206*

Ebony of very superior quality is procurable in these districts as well as the Northern Circars. Mr. Rohde has received 16 inch planks of a fine uniform black. Ebony is much affected by the weather, on which account European cabinet makers seldom use it except in veneer.

The tree bearing the name " Achay " at Madras is *Bauhinia tomentosa*.—*M. E. J. R.*

(682) *DIOSPYROS GLUTINOSA*. EBENACEÆ.

Gaub, HIND. | Panichakai, TAM.

A small tree, bearing a rusty coloured fruit abounding in a glutinous astringent juice, obnoxious to insects and used by book binders, and also for soaking fishing nets in.

(683) *DYOSPYROS EBENUM*, (*Tay, Bur.*) is plentiful in the upper provinces of Birman, growing generally in the neighbourhood of teak : leaf very small. Towards the close of the dry season, the leaves are annually shed, like those of the teak, at a particular season, which distinguishes it prominently, in a country where almost every tree is ever-green. Little use is made of the timber. The specimens brought were black, and of a fine grain, but inferior to that used by our cabinet makers.—*Malcolm's Travels in South Eastern Asia, Vol. I, p. 186.*

(684) *DIOSPYROS MOLLIS*.

Ma-kleu, BURM.

The celebrated vegetable dye, the Shan black dye, is made from the fruit of this species of ebony, which is said to grow on the mountains that separate the Province of Tavoy from the Siamese territories. Isolated plants may be seen in the gardens of Tavoy, and Maulmañ.—*Mason.*

(685) *DIPTEROCARPEÆ*. Dr. Wight gives descriptions of the resiniferous and balsamiferous trees of India. Under the head *Dipterocarpeæ*

## DIVORCE.

he observes—The trees of this order growing in Madras are all natives of the hilly tracts of the Balaghaut. In Sylhet, Chittagong and Pegu where they abound, they occupy the plains. In Java one species *Dipterocarpus (littoralis)* is found on the sea shore.

(686) DIPTEROCARPUS. Two species (*Kunnen-ben* and the *Kun-nyin-se*, Bur.) are two Burmese trees of the same kind, one bearing a white fruit, and the other red. Both are very large trees, and excellent for planks, boats, &c. The boiled sap is a very beautiful varnish. Torches are often dipped in it, to increase their brilliancy, and sometimes made of it, mixed with saw dust. The varnish at Rangoon costs, at retail, four annas a viss, or about 6d. sterling for four pounds.—*Malcolm's South Eastern Asia*, Vol. I, p. 188.

(687) DIPTEROCARPUS GRANDIFLORA. Grows tall and slender, to a prodigious height, throwing out branches only towards the summit. It yields a valuable resin, used in torches, and for paying boats. The timber is excellent, and is used for masts, bridges, and long reaches.—*Malcolm's Travels in South Eastern Asia*, Vol. I, p. 188.

(688) DITA. The sap of this tree is used by the wild tribes of Mindoro, to poison their arrows.

(689) DIVINATION. This is a regular science among Malays who resort to diviners on all occasions of importance—as for instance the almost universal custom in all nations of fixing on a propitious day to commence a journey or any undertaking. The commonest system is analogous to the Roman sortes—a Koran is used for this purpose, they have also books filled with sentences and words, the person consulting them cuts in with a Kris and the sentence marked by the Kris point is interpreted to suit the wants and wishes of all parties.—*Journal of Indian Archipelago*, No. 8, Vol. V, August, 1851.

(690) DIVORCE. Mahomedans in India follow the Koran and Shurra, and marry up to four wives, though some take into their households a far greater number of women, under different designations. Mrs. Meer Hoossain Ally had heard of princes in Hindustan possessing seven or eight hundred, and Tippee Sultau had no less than nine hundred women. In Madras some of these are known as the "*Harm*" which term is there applied to purchased women associating with their lord, but in Hindustan such are termed "*Doolee*" wives. These are not the "*Kuneez*" or slave girls, who are servants. There are three forms of "*Tulaq*" Repudiation or Divorce, amongst Mahomedans in India, 1st. *Tulaq-i-byn*, which consists in the husband only once saying to his wife "I have divorced" you; 2nd. "*Tulaq-i; rujaee*" in repeating the same twice, and 3d. "*Tulaq-i-mootuluqa*" in three similar repetitions.

## DOG. CANIS.

(691) DOG. CANIS. The dog, which is known in Bengal by the name of the Nepal dog, is, properly speaking, a native of the upper and lower Thibets, whence it is usually brought to Nepal. It is a fierce and surly creature, about the size of an English Newfoundland, and covered with thick long hair. It is reckoned to be a good watch-dog, and never to sleep at night. Another animal to be found in the Nepal hills of worthy description is the Dhole or wild-dog. These animals are found in packs varying from fifty to two hundred, and the havoc committed by them among the flocks of sheep and hill cattle is incredible. Their destruction of deer also is immense, and their mode of doing so may be worthy of mention. In size the wild-dog is little larger than the common jackal of India, but longer in the body and possessing much greater power, with a very formidable set of jaws: colour, a rich reddish-brown, with scenting qualities of the highest order.

Soon after nightfall the pack assemble at a given cry, when they disperse in threes and fours in search of game. The first party that hit off the trail, open, when the whole pack rush to them, and when all are assembled fasten to the trail and off they go. The deer soon become alarmed and double, when the pack immediately tell off in parties, each one rushing to the different passes for which deer are known to make, and on the deer attempting to pass either, he is immediately seized by the party, who utter a simultaneous cry, and the whole pack then rush in and the deer is at once devoured. Fresh game is next sought, and in the same way destroyed, and this species of hunting is continued according to the size of pack, till all their appetites are appeased, when they retire to their almost inaccessible fastnesses in the rocks, and remain for three or four days, until hunger again drives them forth on another excursion.

From their destructive qualities, the wild-dogs hardly ever remain longer than a month in the same locality, having in that time effectually scared away all the deer for miles round. Captain Smith never knew them to attack man, and even when severely wounded they will only snap after the manner of a wounded jackal. When deer are not procurable, they will attack even bears.—*Smith's Nepal*. Arthur Grote, Esq., C. S., sent to the Bengal Asiatic Society, the skins and skeletons of a mature female, and male  $\frac{1}{3}$  grown, of the ordinary wild dog so called, of this country, from Chalbasa, Central India. These animals are specifically identical with a particularly fine living adult male sent down from Upper Assam; and this appears to be the ordinary species alike of the Himalaya and of Central and S. India. *Canis Dakhnensis*, Sykes, and *C. Primævus*, Hodgson; and a Malayan specimen in that museum, which is taken to be *C. sumatrensis*, Hardwicke, would appear to

differ only in the considerably deeper tint of its rufous colouring. — *Jour. Asia, Soci. of Beng.* Nov. 1856, p. 440.

(692) DEO-DHUNGA. In a report of the late meeting of the Bengal Asiatic Society, it was announced that a peak situated North East of Kathmandu, and in East Longitude 87° had at length been definitely ascertained by the Surveyor General, Colonel Waugh, to be upwards of 29,000 feet high, and consequently to be the loftiest yet known peak of the Himalaya. That name is Dēva-dhūṅgā, or holy hill. Thus Dēodhūṅgā and Mount Everest are both "about 100 miles N. E. of Kathmandu;" both are midway between Gosainthān and Kaugchun. — *Beng. As. Soc. Jour.* No. V. of 1856.

(693) DHOURAH WOOD.

Dhowra, TEL.

(694) DOLICHOS CATIANY. Red gram. Carramoodloo, TEL. | Kauramanyapayaroo, Bullar, HIND. | TAM.

(695) DOLICHOS CULTRATUS. Red gram. Karamannic, TAM. | Bullar, HIND. Karamoodloo, TEL. |

(696) DOLICHOS CULTRATUS, var, white gram.

Chaday Karamanec, | Kara moodloo, TEL. TAM. | Safaid Bullar HIND.

(697) DOLICHOS FALCATUS.

Itoo mungee tiga, TEL.

Root tuberous. Stems twining, smooth; Leaflets somewhat three-lobed, smooth. Racemes short, few flowered; Legumes linear.

It is common in hedges, thickets, &c., where the soil is rich and moist. Flowers during the cold season. The tuberous roots are cut by the natives into the form of beads, and strung and worn round the neck to cure purging in children. — *Roxb. Flora Indica*, Vol. 3, p. 311.

(698) DOLICHOS GLADIATUS, JACQ.

Coli-averay Kai, TAM. | Chotie sayme ke pullie, DUK.

This valuable legume differs little from the Segapoo averay kai, but in general, does not grow to so large a size. — *Ainslie*, p. 233.

(699) DOLICHOS LABLAB, Lin. DOLICHOS SPICATUS, *Roxb.*

Avery kai, TAM. | Chickoodie kaia, TEL. Saym ke pullie, DUK. |

This pulse the Natives eat as we do French beans (pod and all); it is reckoned excellent in curries and other dishes. — *Ainslie*.

(700) Chotie Sayme ke Pullie, Hind. Dolichos Lablab. — Native Bean. This is a small species of the Dolichos lablab; the legume and seeds are both eaten; it is sown in the rains and sells from one pice or two a seer. — *Riddell*.

(701) DOLICHOS UNIFLORUS, Cooltee, Madras gram.

Woolavaloo, TEL. | Kolloo, TAM. Cooltee, HIND. |

(702) DOMNEEAN, HIND. Female musicians. •

(703) DOONA ZEYLANICA, produces the gum-resin, called by the Cingalese, doon-doo-male.

(704) DOOP or DUP-MARAM, in Malayala and Tamil; it is also named Nadenara, and is to be found in the forests of the coast from north to south. It grows from sixty to eighty feet high, and from two to three feet in diameter. It is a light sort of wood, similar to the white American fir of New England. This is the tree which produces the best description of country dammar, or resin; but it is not so valuable as the dammar from the island of Sumatra. The natives use the large trees as rafts, and as catamarans, and for house-building, and the small spars to make sheds and yards for the native vessels. So long as the moisture of the wood remains, it may be considered to answer these purposes, but when it becomes dry, it is very brittle and of no use.

At Cochin, Edye found the rafters and uprights of the roofs over the ships of war at that port, of this wood, with the purlings of split bamboo over them, and cadjans (cocoa-nut leaves platted), all of which were lashed together by coir yarns. The amount of expense for a roof with sheds was about 350 rupees, or £44 sterling.

One sort of the Dup-maram is named Macdenar, which means long-stringed Dup-maram. It grows to about sixteen inches in diameter, and sixty feet in height. It is not of much use or value.

There is another sort named Paini Dup-maram, which produces a sort of resinous gum. This tree is found in the Cochin and Travancore forests, but is rarely cut down, as the dammar taken from it is valuable, and when mixed with the wood-oil makes the Paini Varnish. This is an article of export to China from Sumatra, where this tree also grows from thirty to fifty feet high, and from two to four feet in diameter, and in greater abundance than on the coast of Malabar. — *Edye, M. and C.*

(705) DRACENA DRACO of Linnæus, affords a similar secretion to that of Calamus draco. A tree of this kind at Teneriffe measures 17 feet in diameter, and is on strong reasons estimated to be 1500 years old. — *O'Shaughnessy*, page 643.

(706) DRAGON BOATS, the name given to the long narrow boats, capable of holding forty to eighty men. These are employed by the Chinese on the festival held on the fifth day of the fifth month usually falling in June, for boat races or rowing matches.

(707) DRAVIDA, or Dravira or Tamul, is the name given to the people and their language occupying the plains of the Carnatic.

(708) DREDGING. "Hints in regard to Dredging observations." The numbers of species, the kinds usually found associating together. The number of living specimens of each. The number of dead. The average

## DRUGS OF TRAVACORE.

## DRUGS OF TRAVANCORE.

age of the specimens, that is, whether young or adult. The general state of the animals and particularly as to the maturity of the eggs or if they have been recently shed. The kind of ground. The depth. The distance from land. The zone whether the (1) Littoral, (2) Laminarian, (3) Coralline, or (4) the Coral. These terms were proposed by the late Professor Edward Forbes, and are fully explained in his writings. 1, the Littoral zone includes the space between high and low water marks: 2, the Laminarian zone is that in which the large tangles or sea weeds flourish and extends from low water mark to a depth of about 15 fathoms. 3, the Coralline zone extends from the depth of 15 to 50 fathoms; sea weeds are scarce, but Corallines abound in this region. 4, the Coral zone is that in which deep sea corals are found and where the depth is beyond 50 fathoms. Any particular currents. What are the mollusca found between tide marks on the neighbouring coast? Is mud present, and if present of what kind? Are any dead shells common of which no living examples occur? What sea-weeds are found? Do the different specimens of the same species vary much in size, form, or colour?

Dredging Paper (partly filled up as a specimen).  
Date ..... October 29, 1859.  
Locality..... Ballaugh, Isle of Man.  
Depth..... Twenty-five fathoms.  
Distance from shore.... Five Miles.

Grounid..... Shelly and gravelly, gravel small.  
Region..... Of Corallines.

SPECIMENS.	No. of living Specimens.	No. of dead Specimens.	OBSERVATIONS.
Nucula-nucleus.....	15	0	In cavities of old shells buried in mud.
Lima hians .....	1	0	In its nest.
Lima Loscombii.....	3	2	Free dead valves thickened.
Pectunculus glycymeris.....	6	7	Young shells common of this species.
Pecten distortus.....	20	6	Both free and fixed; also same with a Byssus.
Psammobia tellinella.....	1	7	Dead shells perforated generally double.
Trochus magus .....	0	2	Much worn.
Trochus Zizyphinus.....	4	0	In gravelly places.

—*Edinburgh New Philosophical Journal*, p. from 206 to 207, New Series, No. 7, Vol. IV. No. July 1856.

(709) DRUGS. Statement showing the Drugs exported from the Madras Territories by Sea for the year 1854.

	Quantity.	Rupees.
Catechu.....	Cwts. 1,369	6,984
Kino.....	66	1,031
Gamboge.....	None.	
Country Sarsaparilla...	269	1,699
Senna.....	404	2,917
Fish oil.....	Gs. 7,21,095	2,06,863
Lemon Grass oil.....	None.	

## (710) DRUGS AND MEDICINAL PRODUCTS OF TRAVANCORE.

Botanical Names.	Malayalim Synonyms.	Parts used.	Abstract of the Diseases in which these drugs are chiefly used.
<i>Abrus precatorius</i> , ... ..	Koonee vayr, ... ..	Seeds and Roots,	Opthalmia. Root a substitute for liquorice. Plentiful.
<i>Acacia arabica</i> , ... ..	Karoovalumputtay, ... ..	Roots and Bark,	Astringent and tonic. Ulcers and cancerous affections.
<i>ferruginea</i> , ... ..	Velvalum pesin, ... ..	Gum, ... ..	
<i>speciosa</i> , ... ..	Vagay puttay, ... ..	Bark, ... ..	Astringent.
<i>Acalypha indica</i> , ... ..	Kooppamunny, ... ..	Whole plant, ... ..	Root cathartic. Leaves used in scabies and cutaneous affections.
<i>Alpinia galanga</i> , ... ..	Kuscholum, ... ..	Roots, ... ..	Substitute for ginger. Used in Fevers, Catarrh and Rheumatism.
<i>racemosa</i> , ... ..	Chittarathay, ... ..	Roots, ... ..	Do.
<i>Anamirta cocculus</i> , ... ..	Poollacorovoo, ... ..	Seeds, ... ..	Poisonous Ointment for cutaneous diseases.
<i>Andropogon muricatum</i> , ... ..	Vettie vayr, ... ..	Roots, ... ..	Stimulant. fevers, bilious affections. Infusion of and oil in gout or rheumatism.
<i>Azadirachta Indica</i> , ... ..	Vapum puttay, ... ..	Bark and Gum, ... ..	Tonic. Fevers. and rheumatism. Leaves in psora. Oil in leprosy. stimulant and anthelmintic.
<i>Acorus calamus aromaticus</i> , ... ..	Vassumboo, ... ..	Roots, ... ..	Aromatic. tonic and purgative. Asthma. dyspepsia, and intermittent fevers.
<i>Adenanthera pavonina</i> , ... ..	Munjadiecooroo, ... ..	Seeds, ... ..	Pulp of seeds in boils and abscesses.
<i>Areca catechu</i> , ... ..	Cash eutty, ... ..	Catechu, ... ..	Astringent, fluxes and ulcers. Nuts astringent and tonic.
<i>Agrostis linearis</i> , ... ..	Arugum kelengoo, ... ..	Roots, ... ..	
<i>Andropogon citratus</i> , ... ..	Ranichum, ... ..	Roots, ... ..	Leaves aromatic. In infusion diaphoretic, used in ring-worm. An essential oil in rheumatism.
<i>Boerhavia diffusa</i> , ... ..	Charcena vayr, ... ..	Roots, ... ..	Laxative. Anthelmintic in infusion.
<i>Barringtonia racemosa</i> , ... ..	Somutrapullum, ... ..	Fruit, ... ..	Sternutatory. Cutaneous complaints.
<i>Butea frondosa</i> , ... ..	Porasum verie, ... ..	Seeds, ... ..	Anthelmintic in tape worms.
<i>Cinnamomum iners</i> , ... ..	Vyana, ... ..	Bark, ... ..	Condiment. Seeds in dysentery and fevers.
<i>Calophyllum inophyllum</i> , ... ..	Pinnaypoo, ... ..	Flowers, ... ..	
<i>Clerodendron serratum</i> , ... ..	Tsjeroothakoo, ... ..	Stem, ... ..	Cephalalgia and opthalmia.
<i>Chavica Roxburghii</i> , ... ..	Thirpeleemoolum, ... ..	Stem, ... ..	Febrifuge. Antispasmodic, in asthma &c.
<i>Coccineum jenesstratum</i> , ... ..	Maramunjel, ... ..	Bark, ... ..	Tonic.
<i>Croton tiglium</i> , ... ..	Naroovallum, ... ..	Seeds, ... ..	Purgative. Apoplexy. Paralysis, dropsy.
<i>Cucumis colocynthis</i> , ... ..	Koomutti kai, ... ..	Fruit, ... ..	
<i>Cathartocarpus fistula</i> , ... ..	Konnay kai, ... ..	Pods, ... ..	Laxative. Roots febrifuge.
<i>Cocos nucifera</i> , ... ..	Thennumpisin, ... ..	Gum, ... ..	
<i>Cassia</i> , ... ..	Teromallay konnay, ... ..	Bark, ... ..	

Botanical Names.	Malaylim Synonyms.	Parts used.	Abstract of the diseases in which these drugs are chiefly used.
<i>Cassia sappan</i> ,...	Chuppangoo,	Stem,	Emmenagogue.
<i>Cassia auriculata</i> ,...	Avery verie,	Seeds,	Pulverised in ophthalmia. Bark astringent.
<i>Cassia sophera</i> ,...	Ponnaverie,	...	Bark in infusion in diabetes. Leaves and Bark in ring-worm
<i>Cocculus cordifolius</i> ,...	Seendie kody,	Root and Stem,	Fever and rheumatism. Ulcers. Jaundice.
<i>Calotropis gigantea</i> ,...	Eriedo vayr,	Root,	Leprosy, cutaneous affections. Alterative and purgative
<i>Cyperus juncifolius</i> ,...	Koren-kelengoo,	Root,	...
<i>Plectranthus cardamomum</i> ,...	Thuckollum,	Seeds Husks,	Cordial, stimulant.
<i>Embellica officinalis</i> ,...	Nellikai,	Fruits,	Infusion in fevers and diabetes. Bark astringent, Diarrhoea.
<i>Flacourtia cataphracta</i> ,...	Talishaputree,	Root,	Astringent. Diarrhoea, dysentery and fevers.
<i>Gaillardina Bonducella</i> ,...	Kalichikai,	Nuts,	Tonic and anthelmintic. Fevers.
<i>Gynandropsis pentaphylla</i> ,...	Thyvala vayr,	Roots,	Leprosy and cutaneous diseases.
<i>Garcinia affinis</i> ,...	Koodoooy pully,	Fruits,	Laxative.
<i>Hydnocarpus inebrians</i> ,...	Marotticooroo,	Seeds,	Oil for Rheumatism.
<i>Hemidesmus indicus</i> ,...	Nanoori vayr,	Roots,	Substitute for Sarsaparilla.
<i>Isora corylifolia</i> ,...	Valambere kai,	Fruit,	Bilious affections: in combination
<i>Indigofera emeaphylla</i> ,...	Chemboo neringie,	Whole plant	Antiscorbutic, diuretic, alterative.
„ aul,	Neelum,	...	Alterative. Hepatitis. Calculus. Powdered in epilepsy and erysipelas.
<i>Ixora coccinea</i> ,...	Sentheythy vayr,	Buds,	Diseases of the kidneys. Externally in cutaneous diseases.
<i>Michellia Rheedii</i> ,...	Chembuga mottoo,	Gum,	Cephalagia Ophthalmia.
<i>Moringa pterygosperma</i> ,...	Moomgo pissin,	...	Cephalalgia, Local to buboes.
<i>Macaranga indica</i> ,...	Vuttathamara pissin,	Bark,	...
<i>Morinda tomentosa</i> ,...	Mungenatee puttay,	...	...
<i>Mimosa abstergens</i> ,...	Cheeya kai,	Pods,	Detergent.
<i>Oldenlandia umbellata</i> ,...	Chaya vayr,	Roots,	Asthma. Cutaneous diseases. Poisonous bites.
<i>Pterocarpus santalinus</i> ,...	Shenchundanum,	Stem,	Hemorrhoids in powder, Externally in scabies and ophthalmia.
<i>Piper nigrum</i> ,...	Chevicum,	Roots,	onic stimulant and cordial.
<i>Pothos officinalis</i> ,...	Athithripelec,	...	Pericarp in leprosy. In infusion in coughs and rheumatism.
<i>Physalis sonnifera</i> ,...	Amookoorum,	Root,	Deobstruent and diuretic, powerfully narcotic.
<i>Pterocarpus marsupium</i> ,...	Oothinvaynga pissin,	Gum,	Tonic
<i>Pavetta indica</i> ,...	Pavetta vayr,	Roots,	Aperient.
<i>Plumbago zeylanica</i> ,...	Kodoovay vayr,	Roots,	...
<i>Pongamia glabra</i> ,...	Pongum,	Roots,	Oil of the seeds in cutaneous eruptions.
<i>Quercus infectoria</i> ,...	Maya kai,	Fruits,	...
<i>Ricinus communis</i> ,...	Amumakooareesee,	Seeds,	Purgative.
<i>Santalum album</i> ,...	Cunthamum,	Stem,	Sedative and cooling. Fevers. Bilious affections.
<i>Strychnos nux vomica</i> ,...	Canjeram vayr,	Roots and Nuts,	Bitter. Intermittent fevers. Paralysis.
<i>Sida retusa</i> ,...	Coorronthotty vayr,	Roots,	Rheumatism.
<i>Sapindus emarginatus</i> ,...	Naey kutton kai,	Fruits,	Expectorant, Epilepsy.
<i>Semecarpus anacardium</i> ,...	Chrancotta,	Nuts,	Rheumatism. Leprosy, and Scrophula.
<i>Strychnos potatorum</i> ,...	Tettan kottay,	Nuts,	Emetic.
<i>Samadera Indica</i> ,...	Karingotta cooroo,	Seeds,	Oil in rheumatism.
<i>Solanum Jacquini</i> ,...	Kunden kutheree,	Whole Plant.	Fruit bitter, expectorant. Consumption and asthma.
„ trilobatum,	Thoothoovay,	...	Consumption.
<i>Tephrosia purpurea</i> ,...	Kolungy vayr,	Roots,	In infusion for checking vomiting; dyspepsia.
<i>Terminalia bellerica</i> ,...	Konica,	...	Intoxicating. Ophthalmia.
<i>Thespesia populnea</i> ,...	Chelanthe puttay,	Bark.	Astringent. Externally in cutaneous complaints.
<i>Terminalia chebula</i> ,...	Kurkada sengoo,	...	Purgative. Ophthalmia. Dropsy, and diabetes.
<i>Tribulus lanuginosus</i> ,...	Naungel,	Whole Plant.	Diuretic. Dropsy and Gonorrhoea.
<i>Vitex negundo</i> ,...	Notely vayr,	Roots,	Intermittent and typhus fevers.
<i>Vernonia anthelmintica</i> ,...	Caatoo seeragum,	Seeds,	Fevers and asthma. Anthelmintic.

(711) DRYABALANOPS CAMPHORA Colebr.

Syn. *Shorea camphorifera*. Roxb. (see *Colebrooke, As. Researches*, vol. xii. p. 535.)

A very large tree, a native of Borneo and Sumatra, where it is sometimes found six to seven feet in diameter.

In the cavities of the trunk there occur collections of solid camphor, and of a light fluid called camphor oil. The solid camphor is often deposited in long pieces, weighing over ten pounds. This camphor is highly prized by the Chinese and Japanese, and so rarely finds its way to Europe that it is seldom found even in the richest collections of *Materia Medica*. Mr. Pereira informs us that he has only met with it twice. Dr. Duncan had specimens, of which he published a detailed and interesting account.

It occurred in tabular plates, readily reduced to powder, compact, ringing when shaken in a bottle; it sinks in water, and does not sublime spontaneously. In these characters it differs from common camphor. (See *Laurus camphora*). The fluid camphor is transparent, pale yellow, bitter, slightly viscid, Sp. Gr. 887. On distillation, it yields a volatile oil, and a camphor-like white substance remains in the retort.—*O'Shaughnessy*, page 220.

(712) DUBDUBEA. The Dubdubea is a Nepaul Wood, abounding in the Terai, which is a powerful astringent, and constitutes an article of trade—*Smith's Five Years*, p. 67.

(713) DUGGY. Round timber in Madras from 20 to 40 feet long 1-to-2½ feet square.

(714) DURGAH, a tomb or shrine. There are two noted ones of this kind near and at

six or ten of their *mōoreeds* (or disciples) on such occasions numerous *fuqeers* are likewise present. The four peers having come to an unanimous conclusion, appoint either one of their disciples, or the son of the deceased, if he be found duly qualified. The days of the Sooltan (Tippoo), the individual in charge of this *durgah* used to receive (by order of the Sooltan) rupees corresponding to the number of masts of the vessels that entered the roads or harbour; for every ship three rupees, patamars, &c. two rupees, *munjee*, &c., one rupee: this rule has been abolished since the place has fallen into the hands of the British. There is likewise a pagoda (or Hindoo place of worship) where a grand annual festival takes place, on which occasion an immense concourse of people assemble.

The second *durgah* is situated at Mangalore, on the banks of the river, and consists of a large long tomb with minarets at each extremity. *Low Lungur Shah* (a *fuqeer*) is buried here, whose name it bears. Lamps are burned here every night, and it is chiefly visited by Malabars (a Hindoo caste), but also by Moosulmans and other Hindoos. Most Hindoos, however, frequent *Sheikh Furreed's durgah*. These *durgahs* are resorted to when people are desirous of being freed from any distemper, misfortune, &c. If the individual who is enshrined in the *durgah* have been wealthy, large dinners are provided, *fatecha* offered, and the food distributed to any who choose to partake of it; there being sometimes *Kunchnee ka taefn* (bands of dancing girls) to entertain the guests. Among the great this takes place on every night of the year (and is never observed in the day time); but among the poorer classes of people, every Monday and Thursday or once a week or month.—*Herklots*.

It is said that Java and its dependencies reckons 16,000 of chiefs of villages. We have not been able to verify the calculation. We judge it below the effective number.

We learn the following from the Count de Hogendrop relative to the fertility of Java, and to the resources which it offers. Coup-d'œil sur l'isle de Java, published at Brussels in 1830.

"The soil of Java does not present any products which are exclusively proper to it, but such is its happy fecundity, such is the goodness of its climate that all the productions which Providence has granted to other countries situated between the tropics, can be transplanted there and cultivated with success. If the imperfect knowledge and limited means of the Javanese have only until now permitted them to cultivate rice, coffee, tobacco, sirc, katchany, maize and a little cotton, we may reasonably hope that a gentle and enlightened persuasion, will easily lead them also to cultivate pepper, gambier, cardamums, and the many kinds of tobacco and cotton on procuring for this purpose seeds from Virginia and Brazil; whilst the culture and the manufacture of indigo, sugar, the extensive culture of cotton, coffee, tobacco, the manufacture

## DYAKS.

of potass, of rum, &c, may furnish to European industry powerful means of augmenting products suited to exterior commerce and immense sources of riches and prosperity."

We further add what the same author tells us, "That in 1830, we could calculate that only two-ninths of Java were cultivated, and that the other seven-ninths still presented a vast field for improvement;" which this judicious observer is of opinion "should be introduced with discernment, and without hurting or shackling the system of duties followed in this country."

(716) DYAKS. The people thus denominated must not be confounded with the Daya of the west coast. They inhabit the borders of the river of Banjermassing and some of the other southern rivers, and their proper designation is Ngajur or Blaju. They are also called Kahayan from the great river of that name.

The notions of the Dyaks respecting the spiritual world are in general much confused and at variance with each other. They agree however in the belief in good and evil spirits. The good spirits are divided into two classes, viz. spirits of the world above or of the higher regions, who are comprised under the collective denomination of "Lengiang," and spirits of the lower regions, or more properly such as have their dominion in the waters, in great rivers, and those are called "Jata." The collective name of the evil spirits is "Talepapa," which word signifies in general all bad things.

It is to be observed here that the Dyaks describe the aspect of the regions above as similar to the terrestrial world. Mountains, valleys, streams, lakes &c., &c, are found there as well as here beneath, and the dominions of various spirits are bounded by the different streams and branches of the rivers.—*The Mythology of the Dyaks. By the Rev. T. T. Beeker, Missionary on the South Coast of Borneo.—Journ. of the Ind. Arch. Vol. III, No. 2 of Feb. 1849, page 102.*

(717) **DYEING WITH CHAY-ROOT.** The following is an extract from Dr. Heyne's description of dyeing cotton yarn with chay-root.

The yarn being washed and untwisted that it may not become entangled and being so separated that every part may be equally penetrated by the colouring matter, is divided into bundles of thirty or forty threads, through each of which at the middle and extremities a cotton thread is loosely sewed but so as to allow of every thread being exposed to the sun's rays when hung up and the threads spread out on a bamboo.

The yarn is washed and cleansed in cold water aided by half an hour's manipulation, it is then kept in water in covered vessels till it acquires a putrid smell which takes place in from twenty-four to thirty-six hours, during which it is occasionally pressed and worked for a quarter of an hour together, it is then to be washed as clean as possible, beaten on a stone or earthen pot and then hung up to dry.

While this process is going on a lye is prepared of the ashes of the plantain or other tree in cold water, it is an object to have this lye of sufficient strength which is determined by adding to a small quantity about half as much gingilie oil and giving to it a gentle motion: should it turn immediately white having no visible globules of oil swimming on the surface it is good.

The quantity required of clean lye being poured off and strained, sheep dung in the proportion of three ounces to a pint of lye is dissolved in one half of it and this solution is again strained. The other half of the lye is mixed with half its bulk of gingilie oil and half as much tsiky (the saponaceous water procured during and retained from former process being in fact a solution of soap in water) the two liquors are then mixed together and if things are favorable a milky scum arises.

The proportions required for say half a pound of a yarn would be gingilie oil half a pint by two pints, tsiky, (soapy liquor from former process) a quarter of a pint, sheep dung two or three ounces.

The yarn having been thoroughly imbued with this mordant is dried in the sun for some hours, it is then again soaked and dried as before. The same night it is treated with an additional portion of mordant; is put into covered vessels and allowed to remain till morning. If any mordant remain the same process is again repeated.

The yarn is at night moistened with the lye first prepared diluted with one-third of its bulk of water and put into covered vessels. The yarn in drying, it should be remarked, should have the position constantly changed to prevent the mordants or lye from accumulating in the lower part.

Next day the yarn is spread out to dry on the bamboo, it is taken in at night and treated with lye, this alternate soaking or thorough moisten-

ing with lye at night and exposure during the day are continued without intermission till the yarn appears saturated with lye, or in fact till the oil is converted into soap, this if the lye is sufficiently strong may occupy five days. This is ascertained by washing a few inches from off the bundle in water holding some astringent in solution a whitish scum will arise, and it is from the feeling of this scum when worked between the hands, and the appearance of it afterwards that they determine the state, the workman being satisfied of the completion of this process, the yarn is again moistened for one day, morning and evening, with much diluted lye or plain water. The yarn may be immediately washed but the process is much improved by retaining it for some weeks probably to allow the anamalizing matter to get fixed.

Before washing it thoroughly the yarn is washed in a small quantity of water which receiving the soapy particles in solution is retained by the dyer under the denomination of tsiky, it gradually acquires some consistence and a disagreeable smell.

The yarn is then washed in a tank till nothing of the mordant seemingly remains, but the smell and a certain softness to the touch.

Occasionally the whole process is again repeated.

The yarn being thus thoroughly impregnated with the mordant, a cold infusion of cassah leaves in water is made, and after some hours the yarn is put into it and handled in such a manner as to expose every thread to its action, it is allowed to remain therein all night, the quantity of leaf used in the infusion is so great that it resembles a paste.

Next morning the water is wrung out from the yarn, the adhering leaves are shaken off and fresh ones with an equal quantity of chay-root substituted for half a pound of yarn, a handful of each is sufficient: after two hours the yarn is laid in the liquor.

The same process is repeated on the third day; by this time the yarn usually changes to a reddish yellow colour with occasional red spots, a liquor in which to soak the yarn is now prepared of a handful of chayroot in water.

On the fourth day the yarn will appear in the evening of a light red colour, it is to be treated in the same manner as on preceding days and a similar liquor to the last named is prepared for soaking it in at night.

On the fifth day the yarn is washed in a tank and afterwards dried in the sun: as usual for soaking it in at night, a liquor is prepared of pounded cassah leaves mixed with gingilie oil sufficient to form a dry paste of which about half an ounce is mixed in the usual portion of water after standing two hours a handful of chayroot is added and the yarn immediately immersed for the night.

## DYEING.

The mode of proceeding on the sixth day is precisely similar, but the liquor for the night is prepared wholly of chayroot.

On the seventh day the yarn is again washed, dried, &c. on this and the next day it is immersed in a liquor composed of equal parts of cassah leaves and chayroot in water.

The yarn is now boiled in a liquor composed of that strained from it at the last night's process with the addition of chay-root a handful for half a pound of yarn and sufficient water to give room to agitate the yarn freely. The pot containing the liquor is placed on the fire which is kept up briskly till it begins to boil, it is then kept simmering till a rose colored froth rises and covers the surface when the fire is withdrawn and the pot with its contents allowed to cool gradually; during the boiling, the contents of the pot is stirred quickly so as to expose the yarn as little as possible to the action of the air, when cold the yarn is taken out and washed in a tank beaten as usual and dried in the sun; its colour should be a bright and lively red, if it fails it is occasionally brightened by steeping once more in a liquor composed with cassah leaves and chayroot, the former being mixed first with a little gingilie oil, a temporary brilliancy is further given by putting it in a cold infusion of safar wood.

The process appears to have been introduced for nearly eighty years into Europe: of late, improvements have been made but the process is still a tedious one: in Ure's Dictionary of Arts under "Madder," several processes are described with minuteness: the following is one in which the several processes in use at Elberfoia are enumerated.

1. Cleaning the cotton by boiling in a weak alkaline bath for four hours; cooling and rinsing.

2. Working it thoroughly four times over in a steep consisting of 300 lbs. of water, 15 lbs. of potash, 1 pailful of sheep's dung, and 12½ lbs. olive oil, in which it should remain during night. Next day it is drained for an hour, wrung out and dried, this treatment with the dung steep and drying is repeated three times.

3. It is now worked in a bath containing 120 quarts of water, 18 lbs. of potash and six quarts of olive oil, then wrung out and dried, this steep is repeated four times.

4. Steeping for a night in the river is the next process; a slight rinsing wringing and drying in the air.

## DYEING.

5. Bath made of a decoction at 100° F. of semul and not galls in which the goods remain during the night, they are then strongly wrung and dried in the air.

6. Aluming with the addition of potash and chalk; wringing, working it well through this bath where it is left during the night.

7. Draining, and strong rinsing, the following day piling up in a water cistern.

8. Rinsing repeated next day and steeping in water to remove any excess of alum from the fibres, the goods continue in the water till taken to the dyeing bath.

9. The maddering is made with addition of blood, sumach and nut galls, the bath is brought to the boil in 1¼ hour and kept boiling for an half an hour.

10. The yarn is rinsed, dried, boiled from 24 to 36 hours in a covered copper, with an oily alkaline liquid; then rinsed twice, laid two days in clean water and dried.

11. Finally the greatest brightness is attained by boiling for three or four hours in a soap bath containing muriate of tin, after which the yarn is rinsed twice, over steeped, and dried.—*Ure's Dictionary of Arts.*

This is an instance of the very little progress that art has made in simplifying a process which at first sight seems unnecessarily tedious, the superiority in the result is I think chiefly to be attributed to the solution of salts of tin used to brighten the colours.

In many parts the roots of the morinda umbellata are employed instead of chay-root in dyeing cotton yarn red, the colour is neither so bright or so durable. Dr. Heyne describes the process. Take 3½ lbs. of white cotton yarn and soak it in 1½ lb. of gingilie oil: a strong lye made of the ashes of the milk hedge, and the yarn steeped in it for four nights being dried in the sun during the day, it is then washed in brackish water and dried in the sun.

Five seers (kutchu 13¼ lb. ?) of togara root finely powdered are put into a pot of water together with the yarn and kept all night over a fire of cowdung, in the morning it is taken out and dried in the sun, the same process is repeated for two successive days and nights which completes the process. It is probable that a superior dye might be obtained if the same nicities were observed as in dyeing with chay-root.—*Rhode, M.S.S.*

E

(718) EARTHQUAKE. A severe Earthquake was experienced in Batavia, and over an extensive region in Java, on the 16th of November 1847.—*Journ. of the Indi. Archipelago*, December, 1857, page 361.

(719) EDANAH the Tamil name of a Malabar tree that grows to about forty feet in height, and two and a half in diameter. It is very soft, and not durable: it produces a sort of gum, or resin, like the Payane. The wood is used for catamarans, rafts for heavy timber, canoes, spars for sheds, and other purposes.—*Edge, M. and C.*

(720) EDELLAH, the Malayala name of a tree which grows to about thirty feet high, and twelve inches in diameter. It is used in boats and country vessels; and is designated jungle wood. In consequence of its scarcity it is not much known or used.—*Edge, M. and C.*

(721) EED: ARAB. There are five Eeds, or feasts, held annually by Mahomedans. The two principal ones are the Rumzan feast or Eed-ool-fitr and the Buqr-eed; which are Furz and Soonnut, i. e. commanded to be observed both by God and Mahomed. The other three are, Mohurram, Akhree-char shumbah and Shab-i-burat, which are only soonnut, or commanded by Mahomed.—*Herkl.*

(722) EED-GAH or NUMAZ-GAH, lit: a place of festival or of prayer: a building generally situated without the walls of a town (often amidst gardens), erected on a platform or a pediment three or four feet above the level of the ground, and on an eminence, consisting of a square wall with two or more minarets, and having in the centre, on a level with the ground, three steps, which forms the *mimbar* (or pulpit), from which the *khootba* (or sermon) is read on particular occasions, or on particular feast days, such as those of *buqr-eed* and *rumzan kee eed*, which occupies from an hour and a half to two hours. It is said that the Arabian Prophet, in addressing the congregation, stood on the uppermost step; *Abu Bakur* (his successor) on the second; *Oomur* on the third or lowest; but *Oosman*, observing that at this rate we might descend to the bowels of the earth, fixed upon the middle as the one from which to deliver the sermon; since then it has continued so. This building is merely intended as a signal post for people to assemble at to hear the *Khootba* read. A bamboo, or any other post might answer the same purpose, but a brick building is usually preferred, as being more durable, and affording individuals an opportunity of handing down their names to posterity, by being at the expence of erecting them. It is by no means a sacred edifice.—*Herkl.*

(723) EED-OOI-FIFTR, or Rumzan kee Eed, a mahomedan festival, held on the first day of the tenth month Shuwal.

(724) EEDFEE, Hind, School Holiday.

(725) EHRETIA BUXIFOLIA. ROXB. Root of the Box leaved Ehretia.

Cooroovingie vayr, TAM. | Pale ke jurr, DUK.

This root has, in its more succulent state, a sweetish and somewhat warm taste; and is reckoned by the Vyteans amongst those medicines which assist in altering and purifying the habit in cases of cachexia, and venereal affections of long standing. It is commonly prescribed in decoction. The Hakeems consider it as an antidote to vegetable poisons.—*Ain's Mat. Med.* p. 77.

(726) EHRETIA ARENARIA, Sand Ehretia; Griffith, which is found between 12° and 28° N. L. binds together loose sand, in a minor degree. It may be the same as Ehretia (X) cuneata? Wight Icon. Vol. IV. t. 1385 which grows on sand banks in the beds of all our rivers. *Cleghorn.*

(727) ELÆOCOCCA VERNICIA. Dryandra Vernicia, CORR. The varnish tree of China.

(728) ELAVUM, the Tamil name of the wild cotton tree, which grows to sixty or eighty feet high, and from four to six feet in diameter. It is a very soft, light wood, and used by the natives for catamarans and canoes; and also for rafting the heavy timber from the forests: it is not durable or of much value.—*Edge, M. and C.*

(729) ELEPHANTS. The catching and taming of wild elephants furnish a large source of revenue to the Nepaul government. In taking them, the taroos or elephant catchers, having marked down a wild herd of three hundred or four hundred elephants, the following preparations are made. About two hundred taroos collect together, mounted upon elephants, and accompanied by two large "taking elephants," highly fed, and thereby kept always must (sensual.) The herd of wild elephants having been started, they get away trumpeting and whistling into the thickest part of the forest, hotly pursued by the mounted taroos, each of whom is provided with three or more nooses, called the moosack, which is made of very strong ran hide, well soaked in oil, and so ingeniously contrived, that when once attached to the elephant, the hind legs are gradually drawn together at every step he takes, until he is brought to a complete standstill. The chase continues frequently for twenty miles at full speed, until in fact, the wild herd becomes blown and is brought to a stand. The danger then commences, from the wild ones dashing at their pursuers, in their turn causing the

## EMBROIDERY.

most intense excitement during half an hour, until the arrival of the two must elephants whose bulk prevents their keeping up with the more active ones, ridden by the taroos. These two elephants, each having three keepers upon their backs, dash into the herd. Their appearance, accompanied by the powerful nauseous odour emitted by must elephants, creates an immediate panic among the wild ones and soon paralyzes their efforts of resistance. The active little taroos now slide down from their steeds, and under cover of one of the must elephants, who pushes himself forcibly against the wild one selected from the herd, they, in a most dexterous and daring manner, slip the moosack on to each of the hind legs, which performance occupies about three minutes. The noosed elephant is then allowed to depart, and he goes off evidently delighted; but as the noose becomes contracted at every stride, he finds his intended flight brought to a close, at a distance of sixty or seventy yards. After operating upon about fifty wild Elephants in a similar manner, the Taroos permit the remainder of the herd to abscond, and employ themselves in fastening the noosed elephants to separate trees, where they are detained from two to three weeks under the careful charge of the takers. If any of the captured show symptoms of violence, they are immediately punished most severely by two of the large tame elephants, who belabour them unmercifully with their trunks. Two such thrashings effectually cure the most insubordinate, and at the expiration of six weeks, the once free and independant denizen of the forest has a keeper on his back, and becomes as quiet as if he had been in a state of subjection all his life.

As Chittagong is renowned for the beauty and size of its elephants, so is Nepaul celebrated for the hardness and ugliness of her produce: a fatal peculiarity extending to the Nepaulese themselves. The full-grown female elephants seldom exceed seven feet and a half in height, but the males of forty years old, at which age they are considered to be full-grown, are fine fellows, averaging from nine to eleven feet. One elephant was eleven feet four inches in stature.—*Smith's Nepaul.*

(730) **ELOOPIE** OR **ELUPE MARAM.** The Malayala name of a tree which grows to fifty feet in height, and two and a half feet in diameter. It is said to be a useful timber, and is found to be durable in native vessels for planks, beams, &c. It produces a fruit from which an oil is extracted, which is used for lamps and other purposes.—*Edye, M. and C.*

(731) **EMBROIDERY.** In Southern India this art is practiced, chiefly, at the towns of Tanjore, Madras, and Secunderabad. The Tanjore, and Madras works are of very superior in quality. Under this head may be classed a variety of fancy articles of great merit particularly pocket handkerchiefs, and worked muslin dresses,

## ENTOMOLOGY.

scarfs which show great taste in the patterns and beautiful finish.

*Embroidery in Gold.*—This art furnishes some of the most gorgeous and expensive manufactures for which India has been long celebrated. The taste and judgment evinced in the blending of brilliant colors and contrasting them with gold and silver on grounds of velvet, satin, silk, or muslin, proves that in this manufacture, India stands unrivalled. Some are very gorgeous Shaminahs and Elephant saddle cloths.

*Embroidery in Silver.* The *Gold and Silver Fancy Fringes of Hyderabad* are deserving of mention. Small samples of *Solid Silver wire Fringes and Ornaments* from Madura deserve notice, but they are surpassed by the silver thread of Hyderabad.

(732) **ENGELHARDTIA LESCHEN.** This plant grows well in the plains of the North West Provinces but does not fruit.

(733) **ENTOMOLOGY** of the Himalayas and India.

*Influence of Temperature and of Moisture.*—In those regions of the world where we find a multiplicity of genera of animals, united with a prolificness of species, we may naturally imagine that circumstances are admirably suited to their existence; and, on the contrary, where we find a small number of genera, and in many instances a diminutive form, and a paucity of individuals, we arrive at an opposite conclusion. Now, if we search for the cause of these discrepancies, we shall find it to depend in a great measure on the influence of temperature. Let us examine, then, in what portion of the globe a superfecundity of organized life exists. Certainly not at the poles, or even in the temperate zones; to the tropical and equatorial regions we must next proceed, and it is there, in those warmer districts of the earth that we find the energies of life more early developed, and vigour and productiveness seem the characteristics of the clime. These remarks apply not less to animal than to vegetable life, for no where do the Herbivora abound more than in warm regions, and no where do we meet with more luxuriance of foliage, or a greater exuberance of arboreal vegetation, than within the tropics. As we recede from the equator, and approximate to the poles, temperature gradually diminishes; and probably nearly in the same proportion as heat decreases, so shall we find the decrease of animal and vegetable species, till we arrive at that degree of cold where vegetation is stunted, circulation languid, animation becomes suspended, and existence is scarcely tenable, if not actually destroyed.

To obviate the effects occasioned by a low temperature, some animals burrow in the earth, and pass the winter in inactivity and torpor; others again, gifted with extraordinary locomotive powers, migrate into milder regions in quest of

food, which the rigour of a brumal season and a northern climate has rendered precarious. It appears an observation worthy of attention, that at the very period the migratory birds visit the south. Insects are already teeming into life, while vegetation has arrived at a state of forwardness sufficient to support, as it were, the expected increase of animal beings. We infer, then, that as vegetation is apparently regulated and influenced by temperature, so animalization is in a measure dependent on vegetation as a secondary cause. It may naturally be expected, in a gigantic country like India, whose superficial area is nearly one million and a half of miles in extent, that great diversities of climate will be found; and when we take into our consideration the altitude of its mountains, surpassing in grandeur the Andes of the American world, we may expect every gradation of temperature which can occur, from the intense cold of the eternally snow-capped height, to the baneful heat of the tropical valley. The elevation of the land above the ocean, the height and direction of its mountain ranges promoting or checking radiation, its mighty rivers and interminable jungles, its soil, strata, and arid deserts, absorbing and radiating heat, exert their varied influences, and modify the temperature of that extensive Continent; and yet, admitting thus much, I cannot help stating an opinion, that according to the extent of the country, no other portion of the globe enjoys a more general and equable uniformity of temperature than India. This may satisfactorily be proved, provided we take as the basis of our argument the wide range of region, over which not individual species, but whole genera of Insects extend, and the general uniformity of oriental vegetation. Before dismissing the important subject of temperature, it is necessary to offer a few remarks on the variation of heat and cold throughout the summers and winters in the Himalayas and in India. In the former Dr. Royle states, in his admirable pages, that the Flora of the Himalayas in the spring and summer of the year resembles that of Europe, while in the rainy season it becomes intermixed with tropic-like vegetation; and hence there is a certain admixture of genera belonging to temperate and tropical climes. The change of temperature and of moisture producing a new vegetation, exercises a corresponding influence over the distribution of Insects throughout the same country; and consequently we have reason to expect, as will afterwards appear in these remarks, that its entomological character is also twofold, uniting in itself that of both zones. This intermingling of genera of tropical and temperate regions will ever probably be found more perceptible in the rainy season, in advancing from the valley to the mountain height; and perhaps we ought to know the results of the following researches, before we attempt to arrive at any conclusion respecting the distribution of

animal groups in the Himalayas or in India. It was therefore suggested to future travellers in these magnificent regions, first, to endeavour to ascertain the differences of climate, and the causes which affect its temperature; secondly, to find out the average limit to which tropical forms extend, to state where they most abound, where begin to lessen, and finally terminate; thirdly, to note in what proportions the genera of tropical and temperate climes are intermingled; fourthly, at what altitude temperate forms predominate over tropical; and, lastly, to mention as nearly as it is possible the range of any group of animals in preference to that of any individual species: both objects, however, are desirable. In addition to the above desiderata, it will be necessary to note the seasons of Insects and times of their appearance, the soil in which they are found, and the vegetation upon which they live; since the distribution of animals in general is greatly dependent on food, which food will abound, or be found deficient, according to the richness or poverty of the soil, or according as the degrees of heat and moisture influence the same. It appears to me, that it is chiefly in swamps, and in low and marshy lands acted on by the rays of the sun, where there is a union of heat and moisture, that the major part of Insects seem particularly to flourish. In such localities we find genera more abundant, a great increase of species, the number of individuals prodigiously augmented, and the energies of life more rapidly developed. Animals appear more than usually productive, either in the alluvium of mighty rivers, or in the tropical jungle. It was on the banks of the Nile, amid its slime, acted on by the influence of the sun, that the doctrine of spontaneous generation originated, and we are told also entertained by the ancient Brahmaus on the banks of the Ganges, as seen in *Susruta*. It is in like situations, where heat and moisture predominate, that nature still exhibits her surpassing and inexhaustible fecundity.

If we next turn our attention to the tropical jungle, we meet there with nearly an equally teeming exuberance and productiveness of species. The heavy tropical rains saturating the accumulated mass of heated leaves, and vegetable matter, considerable vapour is produced peculiarly adapted to increase insect life; and it is not a little singular, that as soon as the first showers fall in these regions, all nature becomes reanimate; and as the rains increase, so do the Insects in proportion more and more, till the rainy season fairly sets in, at which period the jungle and the forest literally teem with myriads of insect population, more numerous than the stars of heaven, and as countless as the sands of the sea-shore. In concluding this part of my subject, I need only repeat shortly, that heat and moisture combined, exercise a powerful control over the geographi-

cal distribution of insect life, and that this distribution is also influenced in a greater or less degree by vegetation, as well as by the soil of a country; but these are subjects which require further elucidation.

*Influence of vegetation.*—The entomologist who wishes for accurate information respecting the geographical distribution of Insects over the wide extent of our globe, must take into his consideration not only the influence of temperature, but that of vegetation; nor should he omit to note the varieties of soil which materially influence it. The dependence of this distribution of animals, although greatly swayed by temperature, is no less so by the supply of food and nourishment they can obtain. Insects are designated according to the kind of food they consume, as carnivorous or phytyvorous; and in proportion as food is ample or deficient, so probably they abound in numbers, or decrease and vary in magnitude and form. To its abundance we may in some measure attribute size, to its deficiency the frequency of dwarfishness of stature, immaturity, and many of the numerous crippled specimens, as also some of the monstrosities found in our collections. The great Latreille has justly observed, that where the empire of Flora ends, there also terminates that of Zoology; and there is little doubt, that where vegetation is richest, there animal groups also will be found most abundant in genera, species, and individuals, not only those which are herbivorous, but those also which are carnivorous.

It is not the intention here to enter into any details respecting the Himalayan or Indian Flora. If the reader requires information on these points, we refer him at once to the accurate and invaluable pages of Dr. Wallich and Dr. Royle; and as we at present look merely to the vegetation, as influencing in a great measure the character of the entomology of the country, a concise outline of the leading features of the Botany of those regions is all that is here requisite. Throughout India, according to the above authorities, there appears to be an uniformity of vegetation, tropical species greatly predominating over those of the temperate zones; there occurs also a considerable admixture of genera belonging to temperate climes, and at a high elevation plants abound, which are indicative of Alpine regions. Several genera appear common to Europe, North America, and India; and in some instances identical species have been recognized as existing in Europe and in Asia, as well as in the New World. It still remains, however, with the botanist to determine the similarity of vegetation in Western India and Africa, a similarity which it is anticipated will be eventually found to exist, if not at present actually known—a similarity this writer is led to suspect solely from observing a great resemblance in the character of the

entomology of Western India and Eastern Africa. Vide p. 159 of the "Illustrations," where the similarity of vegetation in parts of India and in Western Africa is referred to, as originally remarked by Mr. Brown, and which has been confirmed by subsequent discoveries.—*J. F. R.* In many instances cognate species of Insects appear both in Africa and Asia, which, by a careless observer, might be considered only as varieties; they are, however, on examination, sufficiently distinct, and he therefore thinks himself justified in esteeming them the representatives of their respective countries, as undoubtedly they fulfil the same offices and functions in both. In several cases we meet with identity of species in Asia and Africa; and there is an observation he has made, worthy of still further investigation, that most of the Insects which are identical in both countries, are either coprophagous or phytyphagous; in short, vegetable feeders, which circumstance would lead one to suppose a similarity of vegetation in the different regions.

The writer thus continues: It may here be expected, perhaps, that I should state the relative proportions of the carnivorous and phytyvorous Insects; and I cannot but regret that I have not as yet followed up my investigations sufficiently to enable me to draw a satisfactory conclusion. Messrs. Kirby and Spence, in their interesting work, speaking of our British Fauna, esteem these groups as nearly equal in number. I must confess my own observation induces me to believe, that the latter greatly exceed the former in our own country. With respect to the phytyvorous group in tropical climates, they certainly greatly out-number the carnivorous; and were it not so, the air in those regions would scarcely be habitable, considering the nauseating effluvia arising from excrementous matter, which the Copridæ in particular tend to neutralise, by consuming, decomposing, and burying in the earth, all that is obnoxious and liable to putrify. In proof of this assertion, I will only here add, that five of the greatest groups with which we are acquainted, namely, the Lamellicornes, the Sternoxes, and the Longicornes, the Curculionidæ and Chrysomelidæ, are almost entirely phytyvorous or xylobious; and it may also be naturally inferred from the superabundance of animal life of all classes within the tropics, particularly the Ruminantia, that there also vegetation will be found most luxuriant; yet, looking to Insects only, we find they are scarcely sufficient to keep in check its excessive exuberance. In addition to multiplied forms of genera, we have an extraordinary increase of species and of individuals. It is in these same prolific regions also, that the mighty Goliath and gigantic Prioidæ abound, where they perforate the trunks of the proudest monarchs of the forest, and hasten them onward to decay; and, by means apparently inefficient, check vegetation. It is time,

however, to add a remark on the carnivorous Insects, which, although inferior in numbers to the phytivorous, are still an important group; and in northern regions, by removing the decomposing matter from the decaying and putrifying carcass, fulfil the functions assigned to them by Providence. In tropical regions they are certainly not always so abundant, as a dead body, from the natural dryness of the air, and intense heat of the sun, is frequently dried up before putridity has made much progress; at least such is the case in the Pampas. I cannot help thinking, however, although our cabinets contain but few species from equinoctial and tropical latitudes that eventually they will be found more numerous, and that in these regions we shall still find them more proportioned to the excess of animal life than appears to be the case at present. Religious prejudice, and the filthy and disgusting habits of these Insects, may be the causes why they have been neglected. In India, if the Necrophaga are not so numerous as elsewhere, yet the numbers of some particular species being excessive beyond measure, are sufficient, perhaps, to compensate for want of variety.

*Range.*—In the consideration of the geographical distribution of Insects, especial notice should be taken of the range over which genera and families extend. From want of attention to this subject, entomologists have not sufficient data to form any just views respecting it. Every naturalist who has studied animals, must be aware that certain tribes, genera, and species are peculiar to particular regions of the globe. On the contrary, in various countries of the earth the Botanist meets with genera of plants which are common to Europe, and the other quarters of the globe, to the Old World as well as to the New. In some instances, identity of species has been recognized in countries remotely situated, between which seas and oceans intervene. It becomes, then, a question of considerable importance to determine if any species of plants have an unlimited or universal range, as probably all those insect races which feed on vegetables are regulated in their distribution by the same laws which govern the distribution of the plants themselves. It must be evident even to the most careless observer, that where the climate is materially changed in temperature, that there vegetation will be proportionately altered, and I imagine that eventually the entomological character of a country will be found much more dependent upon vegetation than has hitherto been allowed. It is true, indeed, that although two countries may agree in temperature and botanical character, the Insects may be totally different in form and appearance; but, in looking to their functions, if we find them the same, or nearly the same, we at once acknowledge the resemblance, and imagine they take the place of other known and existing groups elsewhere; a resemblance

of character, which Messrs. Kirby and Spence have very properly denominated representation, which representation will even be more perceptible as the soil and general characters of the countries accord.

*Influence of Soil.*—Having already seen that both temperature and vegetation exercise a powerful control over the geographical distribution of insect races, there still remains a third subject of inquiry, namely, the influence of soil over the same groups. If we find that in particular rich soils various genera of Insects abound, and that in others of an inferior quality scarcely a species can be met with, may we not naturally infer that there must be some peculiarity in it, and that the animal groups are influenced by their attachment to the same? The Botanist readily admits that vegetation is materially influenced by it, but as yet the Zoologist has made little inquiry respecting this subject, replete as it ever must be with high interest, and well worth most serious attention. Without entering deeply into the geology of India, I may state, on the authority of Colonel Sykes, that the character of the geology of great part of the Peninsula, like that of its vegetation, presents considerable uniformity: unacquainted with its leading features, I can derive my observations respecting it solely from the examination of the genera before me. I will, therefore, merely give concisely what groups attach themselves to particular soils in different countries, and hope that the attempt, imperfect as it is, may induce other naturalists to undertake an inquiry which must lead to very important results. As the mountain, the valley, and the plain, have their own peculiar temperature, vegetation, and soil, they have also particular groups of animals attached to them; and if we look more closely, we shall find that particular families and genera are always to be met with in certain strata and soils, evincing, as it were, a partiality and adaptation, by frequenting and thriving in them.

It may here be worth while to specify some of the genera of Insects attendant on the difference of soil. It is in the sandy districts of our own country that the few species of *Cicindela*, peculiar to our island, occur. *Cicindela maritima*, however, prefers the vicinity of the sea-shore, while several Oriental species, remarkable for their beauty and colouring, delight more in the alluvial soil of rivers. Frequenting the sandy heath are found the splendid *Chlorion*, the fetid *Sphex*, and restless *Ammophilus*, associated with numerous species of *Andrena* and *Nomada*. In the sand, washed from the mountain height, at the sources of our European rivers, some species of *Nebria* and *Psammodytes* are exceedingly abundant. If we visit the parched and burning sands of Africa, we there meet with the rapacious *Anthia*, the desert-loving *Graphiptera*, the burrowing *Scarites*, and countless species of *Heteromera*

and Tetramera. In the same soil also, on the banks of rivers, the genera Epaphius and Trechus, Clivina and Dyschirius, are not unfrequent. On the sand of the sea-shore, Broschus, Bradytus, Pedinus, and Egialia, occur in extraordinary numbers; and where it is habitually covered with salt water at the departure of the tide, we capture Cilleum, Pogonus, Hesperophilus, and Heterocerus, the singularly-formed Bledius, and wonderfully-abundant Ophonus pubescens, all of which I have reason to believe can live submerged beneath the sea a considerable period. Of all other soils, *clay*, (Mr. Shuckhard informs me, that *Andrena labialis* seems peculiarly attached to the London clay,) being naturally cold, attracts fewer Insects, excepting the widely-disseminated Harpali. In gravel, occur the genera Opatrum, Halictus, Cerceris, with numerous colonies of Ants. To a chalky soil are attached the Ophoni, Licini, Chætophora, and various species of Polyommata, *Osmia spinulosa*, and *Andrena hæmorrhoidalis*. When collecting in the mud of the fresh-water marsh, we capture Blethisa, Chlenius, Omaseus, and Agonum, and several Carabidæ. In the slime of brackish waters, several Notaphi are exceedingly abundant, though rare elsewhere; and in company with them we find the subaquatics Elopheorus, Parnus, and springing Salda. It has also been observed, that *Pimelia* is only to be met with where the plants of the genus *Salsola* abound. *Catascopus* and *Elaphrus* frequent the alluvium of rivers. In the mud of lakes and pools various genera of Eupodina, Nothophilus, Bembidiadæ, and Trechidæ occur; and in vegetable mould, where the grass is luxuriant, numerous Diptera, and Larvæ of Lepidoptera, abound. Even in this short and imperfect account of different genera attached to varieties of soil, sufficient has already been stated to prove that it exerts an important control over the range and distribution of Insect races: however, to give the naturalist a better insight into Indian groups, I shall here add an analysis of the leading families and genera which have fallen under my observation, and then conclude with an abstract describing the leading characters of Himalyan and Indian Entomology.

From what has already been written, it will appear that Insects, in their geographical distribution, are influenced by various causes; by temperature, by excess or deficiency of moisture, by the influence of vegetation, and by soil. There is yet, however, another, which materially affects, in some instances, particular groups, namely, the peculiarity of the organization of the Insects themselves. Should any genera of Insects occur which are deficient in the organs of locomotion, they would naturally be restricted to certain localities. How many genera of the Coleoptera and other orders are apterous, and are only found in particular situations; and they

have necessarily particular functions to perform in their restricted limits, and also particular organs adapted to the work assigned them by the Creator. It is to the study then of the differences of organization adapted to differences of situation, and other external circumstances wherever we find Insects, that the entomologist should direct his attention. Contemplating all these instances of adaptation, we reverence the wisdom of a creative and the beneficence of a superintending Providence, that prevents diminution and increase, both extremes of which would prove injurious; for without these "armies of the living God," to keep in check the fecundity of nature, plague and pestilence would walk abroad, and depopulate not a single country, or one quarter of the globe, but the whole earth itself. In concluding my observations on the geographical distribution of Insects, I think it may be stated, that naturalists on this subject have almost exclusively directed their attention to temperature. Where temperature fails, we may turn to vegetation; and if the latter is not sufficient, then to the soil and strata of a country, and even to the organization of the Insects themselves, as well as other causes. No one by itself is sufficient to unravel the difficulties which arise; by uniting all, however, we may in a great measure account for the various discrepancies that occur.

In connexion with the foregoing, the following *Desiderata in the Entomology of India*, by the Rev. F. W. HOPE, are republished from the *Calcutta Journal of Natural History*. No. 1.

1.—Parasites of Birds, Lice, (*Nirmî*). Parasites of *Reptilia* (*Acari*) the name of the genus and species should be given on which they are found. Parasites of Quadrupeds, Ticks, &c.

2.—Endeavour to ascertain if the larger Beetles of India live more than one year; it is important also to ascertain the sexes of the *Atlas Beetles*, and the uses to which their horns are applied.

3.—Ascertain the names of the trees which yield *Resin Anime*; and if any other resins in India contain insects.

4.—Among *Coleoptera*, attend chiefly to the *Lamellicorn Beetles*, *Cetonia*, *Copris*, *Scarabæus*, and *Euprestidæ*.

5.—Ascertain by dissection of gigantic *Coleoptera* if the organs of hearing are in the basis of the antennæ as in *Crustacea*; collect the larvæ of all large *Beetles*, and try if they have the power of hearing.

6.—Send me an account of the habits of *Pausus*, and all the species you can obtain.

7.—Any species of insects infested with worms should be noticed. The worms should have drawings made of them before put into spirits.

8.—All hermaphrodite insects to be noticed, as well as irregular copulation of different genera.

9.—All *Carrion Beetles* to be attended to. They are supposed to be scarce in India. The

prejudice of caste and of religion will not allow many of the natives to touch a dead body of any animal.

10.—All species of silk-bearing insects used in commerce, with their local names and larva, eggs, &c. It is probable we may breed the Atlas Moths in England. Send Larvæ of any, placed in mould, when an opportunity occurs. Colonel Withill introduced alive into England *Bombyx Selene*. Any reports of the annual produce of silk useful.

11.—*Cochineal*. new species; intelligence wanted about its range. How many species in commerce in India. *Lac insect* also.

12.—*Bees*. All species of Bees to be collected. Any accounts of the produce of honey. The *Native names* of Bees much wanted; any thing remarkable in the combs to be figured. All *parasite beetles* found in Bees' nests much wanted. Imports and exports of honey and wax. What are the Bees which produce the wax of the Chinese candles? there are several sorts.

13.—*Ants*. Collect all species of Ants—males, females, and neuters. Ascertain if they *lay up* stores of grain, seeds, &c.; be careful in marking the species. What Ants will drive out the White-Ants? Are the different kinds employed by the natives, to drive out those which annoy them? Experiment on the formic acid. If the White-Ants' nests are ever used as ovens.

14.—*White-Ants*. Collect all species; attend to their parasites, particularly the *Beetles*, which attack them, and are found in their nests.

15.—What insects are eaten as food? Their Indian names. What *Locusts* are eaten, &c.?

16.—Mark those insects which cause any particular destruction of crops, and if the destruction is periodical.

17.—Mark all *luminous* insects. Ascertain if the *Lantern Fly* is *luminous*: it is disputed.

18.—What species of *Mygale* are in India? Their habits. What spiders yield silks, such as are found in commerce?

19.—What species of vesicatory insects are used in India? If any besides *Lytta* and *Mylabris*. If any insects are used medicinally. Their names.

20.—Record any instance of death occasioned by insects, by Bees, Wasps, Hornets, or by Flyblowing, &c. Any ailments produced by insects swallowed in the larva state, &c.

21.—Is *Resine Anime* a preservative against the attacks of insects? Said to be used in corking bottles. Is cloth coloured by *Indigo* ever attacked by the White-Ants and other insects?

22.—Any native remedies against Cockroaches? Collect all species of, and particularly all sorts of *Earwigs*.

23.—Native remedies used after the stings of insects, and the attacks of Gnats, Scorpions, Centipedes, &c.

24.—Note all insects infesting houses. Does any true *Plinius* occur in the East Indies?

25.—Species of *Astrus* attacking quadrupeds; collect them. Do any attack man in the East?

26.—Collect all Aquatic Beetles. Do the *Cyrene* of India emit a peculiar smell? Do the *Carabei* emit an ammoniacal odour?

27.—Collect all Land-Crabs and inland *Crustacea*.

28.—Observe particularly the insects which destroy corn, rice, and all stores. What checks are in use?

29.—Note any extraordinary migration of Caterpillars, and indeed of all other insects.

30.—The *Mole Cricket* of the East Indies. What are its habits?

31.—Note the appearance of the clouds of Locusts.

32.—What are the preservatives used by the Indians in guarding their feathers and shawls? *Colocynth* supposed to be used.

33.—What genera and species of insects are used by the natives, in necklaces and ornaments, &c.?

34.—The habits of the large *Stag Beetles*. Do they destroy leaves?

35.—Note all odorous smelling insects.

36.—Are Beehives in use in India? Send specimens of domestic Bees, if they are domesticated.

37.—Is the *Sherifah*, or Custard-Apple seed, injurious to vermin? Flies are reported never to settle on the tree or its fruits. Ants will attack both.

38.—From what quarters do clouds of Locusts come?—*Madras Lit. Soc. Jour.* quoting "The Entomology of the Himalayas and of India, has been noticed by the Rev. F. W. Hope, F.R.S., F.L.S., &c., President of the Entomological Society of London. (Dr. Royle apologized to the Rev. Mr. Hope and to his readers for the long delay which had occurred in the publishing of this valuable Paper, written for him in 1834, and which had been in type for a considerable time. The Insects of this Author's collection which Mr. Hope described, were collected in the neighbourhood of Saharunpore, in the valleys of the Himalayas, and on the mountains in the neighbourhood of Mussooree, at 6,500 feet of an elevation in 30° of N. latitude, many of the desiderata required by Mr. H. on temperature and vegetation, are detailed throughout Dr. Royle's "Illustrations," and there is a remarkable coincidence in opinion, respecting the distribution of Insects as given by Mr. Hope, with that of Dr. Royle on the geographical distribution of the Flora of the plains and mountains of India.—J. F. R.)

It may by some be considered, he remarks, a proof of presumption, that any individual should undertake to describe the entomo-geographical character of a country which he has never visited; and bold, I am willing to allow, is the attempt to embrace, in my views, not only the

tribution of Insects in the Himalayas, but those also of the whole Continent of India and its adjacent islands. Possessing, however, one of the richest Cabinets of Oriental Entomology to be found in this or any other country, the major part of the species collected at Calcutta, Madras, Poona, and Singapore, and in the islands of Java and Ceylon; and through the kindness of my friends, the late lamented General Hardwicke, Colonels Sykes and Whitehill, Captains Law, Smee, and Smith, having access to their rich and extensive collections from Nepal, Bombay, and the Deccan; I may be enabled, perhaps, from such a mass of materials, to offer some new facts respecting the geographical distribution of Insects, a subject apparently little studied, and certainly not sufficiently appreciated. It is, indeed, with diffidence that I undertake a task beset on all sides with difficulties; and before I enter on it, I claim the indulgence of my readers, and solicit them to regard the present attempt merely as an outline sketch, which can afterwards be filled up with greater accuracy, as our acquaintance with the nature of the soil, and the forms of animal and vegetable life belonging to the East, become better known.

*Analysis.*—Of the Entomology of the Himalayas and of India.

*Cicindelidæ.*—The following genera belonging to this family are not uncommon in India, viz. *Therates*, *Tricondyla*, and *Colliuris*: the two former are characteristic of a southern range, while the latter is abundant throughout the eastern continent. Of Indian *Cicindelidæ*, more than sixty species have fallen under my notice: the most splendid of the race abound in Nepal. Among various species, however, peculiar to the Himalayas, only one approaches the form of our European *Germanica*.

*Dryptidæ.*—As I am only acquainted with a single species of Indian *Casnonia*, I pass on to *Drypta*, a Nepalese individual of this family belonging to the genus *Desera*, Leach, which is described in General Hardwicke's collection. Five others are also recorded as inhabiting India.

*Lebiadæ.*—*Cymindis* has not yet been discovered in India; eventually it may occur in the Himalayas: it is difficult to imagine what genus takes its place. *Lebia* is of rare occurrence in the East; a nondescript, named *unicolor*, in my collection, is from the Himalayas. *Aploa* is found at Poona. *Orthogonius* is common to Africa and Asia: the gigantic species, however, predominate in the latter country.

*Brachinidæ.*—The French writers appear unacquainted with the true type of *Helluo*, exclusively belonging to New Holland: the genus denominated *Omphra* by Dr. Leach, applies solely to the Indian *Helluones*. *Ozaena* and *Pseudo-zaena* inhabit Calcutta and Cayenne; while *Trigonodactyla* appears in Africa and Asia. The *Graphipteræ* of the sandy deserts have no

representative in the East. This genus appears to unite *Brachinus* and *Anthia*: the latter is found throughout the continent of India. Some of the specimens from Nepal, however, are very diminutive. *Aptinus* is partly confined to Northern Europe and America; while true *Brachinus* enjoys the unlimited range of the world. *Catascopus* is found in Nepal, and resembles in its habits *Elaphrus* of Europe, and probably occupies its place. *Dyscolus*, *Promecoptera*, and *Thyreopterus*, prefer the southern tropical regions, and are not found to range as far north as the Himalayas.—*Hope, M. L. J. July 1840, p. 115.*

*Scaritidæ.*—*Siagona atrata* is met with in Nepal and various parts of India: a specimen lately received from Egypt, if not the self-same, is so exceedingly alike in size and sculpture, that it is very difficult to distinguish. The *Scaritidæ* abound in both hemispheres. *Scapterus* of India is represented by *Oxystomus* in the Brazils, and in Africa by *Acanthoscelis*. *Morio* and *Clivina* will, perhaps, be found in both the Old and New World; the latter, indeed, is common to all temperatures; the former may eventually occur in Europe, perhaps in Sicily.—*Hope, M. L. J. July 1840, p. 115.*

*Harpalidæ.*—*Harpali* are found dispersed nearly in all the countries of the globe: they abound more in the arctic than antartic regions. The following genera are recorded as belonging to India, viz. *Harpalus*, *Platymetopus*, *Selenophorus*, *Cyclosomus*, and many others. Some species of *Ophonus* from Bengal and Poona, closely resemble British species.—*Hope, M. L. J. July 1840, p. 115.*

*Pogonidæ.*—Some of the genera of this family are not confined to the temperate zones; the major part of them prefer the polar regions. *Pogonus* and *Cardiaderus* are met with in Asia and Africa; while *Patrobus* is apparently peculiar to Northern Europe and America.—*Hope, M. L. J. July 1840, p. 115.*

*Calathidæ.*—*Dolichus* has not yet been discovered in India: it is probable, however, that it will occur there. *Pristonychus* inhabits Nepal and Europe; while *Calathus* prefers a northern more than a southern climate.—*Hope, M. L. J. July 1840, p. 116.*

*Feroniadæ.*—Instead of finding *Pœcilus* in India we meet with *Trigonotoma*, *Catadromus*, *Lesticus*, and *Distrigus*: most of them peculiar to that continent. *Argutor antiqua* occurs in the East; *Omasus* and *Platysma* in Nepal; and *Steropus* in the vicinity of Poona. It is by mistake that *Percus* has been introduced among oriental genera. *Cephalotes* is found in Nepal and Australia; *Stomis*, *Zabrus*, and *Pelorus* prefer the temperature of Southern Europe. They may, however, be expected to appear in the Himalayas. *Amara* is captured in Japan; *Antaretia* and *Masoreus* are equally natives of

Europe, Africa and Asia. Several nondescript species from the East of the latter genus, are to be found in our English cabinets.—*Hope, M. L. J. July 1840, p. 116.*

*Sphodrindæ*.—The genus *Sphodrus* occurs in Nepal, and the anomalous form of *Mormolyce* in Java and Singapore; which last has been ranged with this family, but appears to be sadly out of place, as it is most likely a subcortical feeder.—*Hope, M. L. J. July 1840, p. 116.*

*Anchomenidæ*.—I am not aware that *Platynus*, *Agonum*, or *Olistophus*, have yet been discovered in India: the two former will no doubt be found in the Himalayas, when the Insects of that country are better known.—*Hope, M. L. J. July 1840, p. 116.*

*Callistidæ*.—*Eponis* and *Chelanius* abound in the tropics: the maculated set appear common to Asia and Africa, each country possessing species almost exact representatives of each other. *Chelanius nepalensis* approaches in form to *Licinus*; and although *Oodes* is widely dispersed over India, no Nepalese examples have yet come under my notice. *Callistus* occurs in the Mysore.—*Hope, M. L. J. July 1840, p. 116.*

*Dicelidæ*.—*Rembus* is found on the Malabar and Coromandel coasts, at Calcutta, and in Nepal: its allied genus, *Licinus*, may be expected to occur, as some Asiatic species have already been described. *Panagæus* has its metropolis in India.—*Hope, M. L. J. July 1840, p. 115.*

*Proceridæ*.—Among the Insects collected by Dr. Wallich, there were four or five species of true *Carabus*, only one of which I was enabled to describe. Several may occur in the colder mountain temperature, and it is probable they will resemble Siberian forms. Wherever the oak grows, there *Calosoma* will be found. Seven eastern species are known to me. *C. indicum* inhabits Nepal. If caterpillars are necessary to keep in check the luxuriance of tropical vegetation, surely the *Calosomata* are equally necessary to keep within bounds these Insects, which sometimes destroy, in northern climes, nearly the foliage of the year.—*Hope, M. L. J. July 1840, p. 117.*

*Nebriidæ*.—This family may be considered as belonging to a Northern and Alpine range. Should it occur in Nepal, it will be found at a considerable elevation, possibly amid the Himalayan snows. As to *Elaphrus*, I have already stated an opinion that *Catascopus* represents it in India.—*Hope, M. L. J. July 1840, p. 117.*

*Bembidiidæ and Trichidæ*.—Of the former family, several genera will no doubt eventually be found in Nepal: a single species of *Tachys* is the only example I am able to record at present. Of the latter, *Stenolophus*, *Acupalpus* and *Tetragonoderus* have occurred: the last of which may take the place of *Bembidium*.—*Hope, M. L. J. July 1840, p. 117.*

*Dyticidæ*.—Aquatic *Colcontera* are apparently

not much influenced by climate: the temperature of water not varying like that of the earth or air, is the reason we meet with the self-same species in the interior of India and the south of France. *Dytiscus* appears confined to Northern Europe or America, while *Cybister* is dispersed throughout the world. *Eunectes* and *Hydaites* belong to Nepal and India, and to the latter country we may add also the following genera, viz. *Colymbetes*, *Laccophilus*, *Noterus*, *Hyphydrus* and *Hydroporus*.—*Hope, M. L. J. July 1840, p. 117.*

*Gyrinidæ*.—Many gigantic species of *Gyrinidæ* abound in India. *Dineutus nepalensis*, *politus*, and *spinosus*, have been found within the Himalayan districts.—*Hope, M. L. J. July 1840, p. 117.*

*Hydrophilidæ*.—Several genera of this family are as widely distributed as the *Dyticidæ*; and most of those found in India inhabit Nepal.—*Hope, M. L. J. July 1840, p. 117.*

*Necrophagæ*.—Differing with most entomologists, I am inclined to believe that the carrion feeders abound more in warm countries than is generally believed. The religious prejudices of the Indians not allowing them to touch a dead body, may account for the few species which have hitherto reached Europe from the East. *Necrophorus*, *Necrodes*, *Silpha*, and *Oiceoptoma*, are met with in India and Nepal. It is probable that *Necrophorus* is more peculiarly adapted to Northern climates, while the remaining genera affect those of tropical regions.—*Hope, M. L. J. July 1840, p. 118.*

*Erotylidæ*.—Passing *Nitidulidæ*, which have been captured in India, we arrive at *Eugidæ* and *Erotylidæ*. In the former family, we find *Triplax*, *Ips*, and *Dacne*; in the latter, *Erotylus*; and next to this group, *Languria* and *Eumorphus* should be placed; genera abounding in species in Nepal and India.—*Hope, M. L. J. July 1840, p. 118.*

*Dermestidæ*.—In General Hardwicke's collection, there is a Nepalese specimen of *Dermestes*, similar in every respect to *D. lardarius* of Europe: a second species is closely allied to *D. vulpinus* of Africa. It is scarcely possible that either of them can have been imported into the Himalayas by commerce. This genus, and its congeners, is apparently a predominant group throughout the world.—*Hope, M. L. J. July 1840, p. 118.*

*Byrrhidæ*.—The foreign *Helocerata* require attentive examination. Among the drawings of the Nepal collection, made purposely for General Hardwicke, two species of *Anthrenus* are figured; they appear novel in form.—*Hope, M. L. J. July 1840, p. 118.*

*Histeridæ*.—This family abounds in India. I am acquainted with more than fifty species from the East: some of the Nepalese specimens are in too mutilated a state to describe.—*Hope, M. L. J. July 1840, p. 118.*

*Lucanidæ*.—I formerly described six species from Nepal: two more from the Himalayas are undescribed in Dr. Royle's collection. In no country is there a greater admixture of temperate and tropical forms than in India; some of the Lucanidæ resemble our British species very closely, while others are the same as those in Java and Singapore. Forty species have been submitted to my inspection. Passalidæ are not equally abundant in the Old as in the New World.—*Hope, M. L. J. July 1840, p. 118.*

*Lamellicornes*.—The celebrated *Ateuchus Ægyptiorum*, or Sacred Beetle, has almost an exact representative in India. *Gymnopleurus capicola*, Hope, and *azureus*, Jab. both of them African species, are replaced in the East by *G. sinuatus*, Jab. and *splendens*, Hope. *Sisyphus* is met with in both hemispheres. *Epirinus* is an African, as well as an oriental form. Several Indian Copridæ resemble those of Egypt. *Copris Midas* of India and Nepal, exactly corresponds with *C. Isidis* of Africa. *C. Sabæus* and *Pithecius* appear common to both continents, and are equally abundant in Ceylon; and several smaller species of *Copris*, from the eastern part of Africa, if not the same, approach so closely to those of Western Asia, as to induce a belief that they are the same Insects, only modified by climate. *Onitis* and *Oniticellus* have also several representatives in both regions, if not in some instances the self-same species. *Onthophagus* abounds more in India than any other country; some of them unrivalled in size, splendour, and variety of form. More than 120 oriental species may be seen in European cabinets; five only now are described from Nepal; double that number, however, are in too mutilated a state to be characterized. *Pactolus* of Nepal and India, is represented in Senegal by *Harpax*, Jab. *Aphodius*, compared with *Onthophagus*, as an Indian group, is quite insignificant; scarcely twenty species are recorded, including those of Manilla and the Eastern Isles: a nondescript from Nepal will appear in the Appendix. There was only a single specimen of *Trox* in General Hardwicke's collection.—*Hope, M. L. J. July 1840, p. 119.*

*Geotrupidæ*.—*Geotrupes* has been denied by Latraille to exist in India; the Baron de Jean also makes no mention of any Eastern species from that country in his last catalogue. Two species are in my recollection; one from Delhi, and a second from Japan; a third also, unique, is among Dr. Royle's Insects from the Himalayas. It is probable that this genus, when found in India, appears on mountains at a considerable elevation: the species also may be the common food of the Shrikes of that country, as they are in Europe, should those birds be found there. *Orphnus*, *Athyreus*, and *Hybosorus*, occur in India. *Bolboceas* appears in some measure to supply the place of *Geotrupes*, which last is not

so important a group in the East, as in a northern region.—*Hope, M. L. J. July 1840, p. 119.*

*Scarabæus*.—Under this term, the gigantic and most remarkable Insects of the Old World are ranged. Four species, allied to *S. Atlas*, Jab. are indigenous to Nepal, a convincing proof that equatorial forms extend beyond the tropics, and that they are found in much colder temperature than is generally believed. There are several genera of *Scarabæidæ*, besides *Oryctes*, found on the Himalayas as yet uncharacterized; some of them approaching African types.—*Hope, M. L. J. July 1840, p. 120.*

*Melolonthidæ*.—Some of the *Melolonthæ* of Nepal are closely allied to the British *M. vulgaris*; others again, with the margins of the thorax serrated, evince their affinity to tropical species. *Geniates*, *Apogonia*, &c. are common to the Himalayas, the whole continent of India, and the Southern Isles.—*Hope, M. L. J. July 1840, p. 120.*

*Mimelæ and Euchlora*.—These genera appear peculiar to the East: in a monograph, read before the Entomological Society, there are thirteen *Mimelæ* described; several from Nepal. *Euchlora* appears wherever *Mimela* ranges, and is more abundant in species.—*Hope, M. L. J. July 1840, p. 120.*

*Popillia*.—This genus appears nearly equally abundant in Asia and Africa, and is common to the Old and New World. Fourteen species have been collected in Nepal. The following genera of *Melolonthidæ*, also, *viz.* *Anomala*, *Hoplia*, *Apogonia*, and *Adoretus*, occur in the same territories.—*Hope, M. L. J. July 1840, p. 120.*

*Trichiidæ*.—*Acanthurus*, *Trichius*, and *Dicro-nosephalus*, inhabit the Himalayas. The first of these forms approaches our European type, the latter is the representative in India of what *Goliathus* is in Africa, and *Incas* in Southern America. *Goliathidæ* is a conspicuous family, and may justly be ranked among the most extraordinary forms of the Insect world.—*Hope, M. L. J. July 1840, p. 120.*

*Cetoniadæ*.—Although I described seventeen species from Nepal, Dr. Royle's collection appears to contain at least six more, entirely new. *Campsiura xanthorhina*, Hope, is represented in Africa by *Cetonia scutellata*, Jab. *C. cornuta*, Jab. is found in Africa, as well as Asia. I am acquainted with more than 111 species from India, and from this surprising number still likely to be greatly increased, it is evident that the metropolis of *Cetoniadæ* is situated in the tropical regions.—*Hope, M. L. J. July 1840, p. 120.*

*Buprestidæ*.—Of this superb and extensive family, comprising at present more than one thousand species, existing in the cabinets of Europe, the most magnificent inhabit India; the splendid *Sternocera* and giant *Catoxantha* range the Equator and the tropics. Ninety species belong to the continent of India, many

to Nepal, the isles of Java and Sumatra: among them are forms of temperate as well as of northern climes.—*Hope, M. L. J. July 1840, p. 121.*

*Elatridæ*.—This family presents us with types of form belonging both to the tropical and temperate regions: the former, however, are few in number, when compared with the latter. Several of the Nepalese *Elatridæ* resemble British species, some so closely as to induce one to imagine that difference of climate is the cause of variety of the species. *Elater murinus*, Fab. of England, is well represented in Nepal by *Elater cœnosus*, Hope; and various species, which in Europe frequent the oak, alder, and willow, have Nepalese species nearly resembling them, and we have stated that there is a correspondence of vegetation between Europe and the Himalayas.—*Hope, M. L. J. July 1840, p. 121.*

*Lampyridæ*.—Passing the *Cebionidæ*, few examples of which occur in India, we arrive at the *Lampyridæ*; and justly may the East boast of its numerous and fine species, unsurpassed probably by those of South America. The warm damp of the jungle is peculiarly adapted to the habits of this family. *Lycus* and *Omalysus*, as well as *Lampyrus* abound in the Himalayan range.—*Hope, M. L. J. July 1840, p. 121.*

*Malacodermata*.—By some writers, the families composing this group are considered rare within the Tropics, and they certainly are more abundant in Nepal than Central India; and yet they are not of rare occurrence. *Anisotelus*, Hope, appears to be peculiar to the East. Several species of *Malachius* and *Melyris* enjoy an Asiatic and African clime.—*Hope, M. L. J. July 1840, p. 121.*

*Cleridæ*.—By the family *Cleridæ* abounding in the East, we arrive at the *Ptinidæ*; they, the latter probably, exist in Nepal; none, however, I believe, have yet been discovered in India, the nearest locality where they are found being the Mauritius. The *Bostrichidæ* are, however, abundant, and it is not unlikely that the *Paussidæ* commence where the *Ptinidæ* terminate.—*Hope, M. L. J. July 1840, p. 121.*

*Curculionidæ*.—Without entering at large into the geographical range of the numerous genera of this family, I briefly state, that Nepal contains many tropical forms, as well as others, which are peculiar to temperate climes, some of them extending from the Himalayas, even to New Holland, particularly *Sipalus*.—*Hope, M. L. J. July 1840, p. 122.*

*Prionidæ*.—By the *Cucujidæ* (common to India and Nepal) we arrive at the *Longicornes*. *Prionus* loves the torrid and tropical zones; some of the Himalayan species indicate an alliance to European types.—*Hope, M. R. J. July 1840, p. 122.*

*Lamiadæ*.—The largest, as well as the most beautiful species of this family, are found in Nepal. *Lamia Roylei*, Hope, is unrivalled in size;

and *L. Wallichii* surpasses all other in beauty and colouring; it is found in Nepal, Japan, at Singapore, and the Isle of Java. *Cerambyx*, *Callidium*, *Clytus*, and *Saperda*, are predominant groups, and are found in all countries and climates. Many Nepalese species exactly represent our European types.—*Hope, M. L. J. July 1840, p. 122.*

*Sagridæ*.—Omitting *Lepturidæ*, confined almost entirely to Northern Europe and America, we arrive at *Sagridæ*. *Donacia* occurs in Java, and we may expect to meet with it in Nepal, and other parts of India; if not, it is probable that *Sagra* takes the place which *Donacia* does in northern regions. Several species of this genus are found on the *Nympheacæ*. I am doubtful if *Sagra* attaches itself to peculiar water-plants, or frequents the same as the former genus. *Megalopus* is found in Nepal, in Africa, as well as South America. *Crioceris* also appears to be a predominant group, while *Adorium* is confined more to Asia than Africa.—*Hope, M. L. J. July 1840, p. 122.*

*Gallerucidæ*.—*Galleruca* and *Auchenia* abound in Nepal, *Halticæ* are found throughout the world, and are intended probably to keep in check particular vegetation. In Europe, the genera *Brassica* and *Sinapis* almost annually suffer from their depredations; they appear to abound more in light and sandy soils; and where lime is used instead of animal manure, the crops are less attacked.—*Hope, M. L. J. July 1840, p. 122.*

*Chrysomelidæ*.—Many of the Nepalese species resemble those of Siberia; others approximate closely to European forms, so much so, that in many instances they appear like one and the self-same insect; and if not the same, they are certainly similar representatives of their respective countries, and probably fulfil the same offices and functions. *Podontia* and *Phyllocharris* seem peculiar to Asia and New Holland.—*Hope, M. L. J. July 1840, p. 123.*

*Eumolpidæ*.—The *Eumolpidæ* of India are not surpassed in beauty or splendour by those of South America: they seldom, however, equal the latter in size. *Clythra* and *Cryptocephalus* occur in the East, both of them abounding more in temperate than tropical countries; in Dr. Royle's collection there were found several undescribed species from the Himalayas.—*Hope, M. L. J. July 1840, p. 123.*

*Cassididæ*.—About fifty species of Indian *Cassida* have come under notice; some of the Nepalese species resemble English specimens, and may be parasitic on the thistle, as they are with us.—*Hope, M. L. J. July 1840, p. 123.*

*Coccinellidæ*.—Although I described twenty new species from General Hardwicke's collection of Nepal Insects, I find five others undescribed in Dr. Royle's collection from the Himalayas. *Coccinella 7-punctata*, Fab. appears common to Eu-

rope and Asia; at least the specimens agree so exactly in every respect, that after a very accurate examination, no important difference can be found; and believing them to be the same, I still cannot imagine that they have been imported into India by commerce. *Endomychus* may eventually be expected to occur in Nepal.—*Hope, M. L. J. July 1840, p. 123.*

*Hispidæ*.—*Hispa erinacea* is abundant in Nepal; and two undescribed species are in Dr. Royle's collection from the same country.—*Hope, M. L. J. July 1840, p. 123.*

*Tenebrionidæ*.—The transition from *Hispidæ* to the present family by means of *Sarrotrium* is rendered easy. *Hegeter* and *Tagenia*, common to India, appear to follow in successive order. Both *Upis* and *Tenebris* are found in the Himalayas, and are abundant in the Tropics.—*Hope, M. L. J. July 1840, p. 123.*

*Pimeliariæ*.—*Pimelia* has not yet been described as existing in India; last year I received two species from the vicinity of Poona. *Sepidium*, *Blaps*, *Eurynotus*, and *Opatrum*, occur in the East; the first prefers the Southern Tropic; the two next appear at Bombay, Calcutta, and Nepal; and the last is widely dispersed throughout the East. Passing *Diaperidæ* and *Cossyphus*, both of them common to Asia and Africa, we next meet with *Cistela* and *Lagria*: the latter apparently a predominant group. *Pyrochroa*, also has been discovered in Java.—*Hope, M. L. J. July 1840, p. 124.*

*Helopidæ*.—This family is the grand receptacle for the various forms of the *Heteromera*. Among the Indian genera we find *Amarygmus*, *Onodulon*, and *Platycrepis*, with several true *Helopidæ*, rivalling in splendour and magnitude those of the South American Continent.—*Hope, M. L. J. July 1840, p. 124.*

*Mordellidæ*.—Most of these Insects are parasites of the *Hymenoptera*, and abound in tropical climates. Their office is probably to keep in check, and prevent the too rapid increase of *Vespidæ* and *Bombidæ*: they are common to the Old and New World.—*Hope, M. L. J. July 1840, p. 124.*

*Cantharidæ*.—The geographical distribution of this family is particularly interesting, as it contains those Insects which are used in Medicine, and denominated Blister Flies. *Lytta gigas*, Fab., is found abundantly in India, and also in Senegal; and there is little doubt that several species of *Mylabris* will be found common to both continents. These vesicatory Insects of the Old World are replaced in the New by the genus *Tetraonyx*.—*Hope, M. L. J. July 1840, p. 124.*

*Staphilinidæ*.—By the families *Notoxidæ* and *Scydmænidæ*, we arrive at the *Pselaphidæ*, and afterwards at the *Brachelytra*, which terminate the *Coleoptera*. *Anthilephila* and *Notoxus* occur in Nepal, and *Scydmænus* in Java; while various other genera of *Staphilinidæ*

are widely dispersed throughout the East.—*Hope, M. L. J. July 1840, p. 124.*

*On the remaining orders*—Having entered fully into the consideration of Eastern *Coleoptera*, it is not my intention at present to go into lengthened details of the remaining Orders. It is sufficient to state, that in all of them there will be found similar and corresponding characters as in the *Coleoptera*. With regard to identity of species, I cannot help remarking, that of *Lepidoptera*, there appear to be a much greater number of species, widely disseminated throughout the world, than of any other Order. In Asia and Europe we meet with *Papilio Machaon*, *Gonepteryx Rhamni*; with some species of *Colias* and *Pontia*, with *Vanessa Atalanta*, and *Cynthia Cardui*; and to these might be added, several identical *Sphingidæ*, particularly *Acherontia*, *Atropos*, *Deilephila*, *Celerio*, and *Sphinx*. Among the *Noctuidæ*, *Geometridæ*, *Totricidæ*, and *Tineidæ*, many species will also be found inhabitants of both continents. In the *Orthoptera*, some *Gryllidæ* are common to countries remotely situated, which may partly be accounted for by the migratory habits of these Insects; and the same remarks may be applied to the *Sphingidæ*. Among the *Blattidæ*, several tropical species range widely; some of them have become naturalized even in a northern climate; and it is no uncommon occurrence to find Indian, Brazilian, and New Holland, species in a high state of perfection alive in the houses of London; and among the Eastern *Neuroptera*, there occur various *Libellulinæ* and *Hemerobidæ*, closely resembling English species.

Among the *Hymenoptera*, may be noticed the universal ranger, *Evania appendigaster*, ever attendant on *Blatta*; some *Ichneumonidæ*, *Crabronidæ*, *Apidæ*, and *Vespidæ*, all of them presenting identical species with those of Great Britain. In referring to the *Diptera*, I need only mention the wide range of the Orange Fly, the same in England, India, and America; the Gnats and Mosquitoes, common to the four quarters of the globe, alike the pest of the Indian and Laplander; and, lastly, various species of *Musca*, as widely dispersed as the half-domesticated sparrow of Great Britain. Passing by the *Aptera*, and the various parasites of birds, quadrupeds, and of man himself, we shall find also among the *Hemiptera*, several identical species of *Pentatoma*, *Reduvius*, *Tetyra*, besides *Cimex lectularius*, the scourge of all countries and climates. It does appear, then, from the above Analysis, that Asia and Europe have many Insects in common, and probably other parts of the world will eventually be found to present not only similar genera and representatives, but also the same identical species, subject to the modifications of climate, and other external circumstances.—*Hope, M. L. J. July 1840, p. 125.*

*Character of Himalayan Entomology.*—The character of Himalayan Entomology is twofold, Asiatic and European; and the intermingling of forms of temperate and tropical climes is one of its most distinguishing peculiarities. In its valleys (probably influenced by the heat and moisture of the jungle) southern forms predominate over northern; and it is not unlikely, that to the uninterrupted belts of jungle stretching along the mountain ranges, we may partly trace several tropical phytivorous genera far beyond their apparent natural limits. Some carnivorous Insects are also found ranging far to the north in the Himalayas; an example of which is *Anthia 6-guttata*, a well-known native of the tropics: the specimens, however, are mere dwarfs, compared with those of Peninsular India, a fact which may be regarded as a proof, that *Anthia* has here reached its extreme limits, and consequently will soon disappear (as is the case) and be represented by another type, fulfilling the same functions, only under a difference of form. The following genera of Himalayan Insects, selected from many others, will evince their tropical relationship. Among the Cicindelidæ, *Colliuris* appears; among the Carabidæ, we find *Desera*, *Omphra*, and *Cyclosomus*; among the Lamellicornes, *Eucolora*, *Mimela*, and *Dicronocephalus*; and to these may be added, *Anisotelus* belonging to Telephoridæ, and *Podontia* and *Phyllocharis* to the Chrysomelidæ: all of them attached to warm countries, and some, indeed, are seldom found but within the Torrid Zone. It is needless to state many genera from the Himalayas evincing an affinity to European types; I may here add, that various Himalayan genera closely approximate Siberian forms, and that some of the species described by Dr. Gebler from the Altaic chain of mountains, particularly some Chrysomelidæ, I believe to be indigenous in both regions, some few, however, are worth noticing, such as *Broschus* and true *Carabus*, *Geotrupes* and *Pimelia*: the two last have been declared by high authority never to be found in India. Regarding identity of Insects occurring in the Himalayas, as well as in Europe, there are several species of the following genera of Coleoptera, namely, *Elatér*, *Melolontha*, *Chrysomela*, *Cassida*, and *Coccinella*, which I cannot help thinking are the same as those of England; particularly as the vegetation of the two countries greatly coincide, for in very many cases, genera, and in some instances the self-same species of plants have been recognized. Among the carnivorous Insects, I believe that *Dermestes lardarius*, and *vulpinus*, *Corynetes violaceus*, and *rufipes*, and some of the Staphilinidæ, are essentially the same in Europe and the Himalayas. Of Lepidoptera, I figure *Papilio Machaon*, because it is evidently the same as what we meet with in England; the same remark will apply to *Vanessa Atalanta*,

and *Cynthia Cardui*. The French entomologists are inclined to regard the Insects of widely separated countries as distinct species; I wish to esteem them as varieties, and I cannot help thinking, that as identity of Plants has been satisfactorily proved by Dr. Boyle, so also we may believe in the identity of Insects in regions widely removed from each other. At any rate, should these varieties eventually prove distinct (which may be ascertained, I think, in the Lepidoptera order, when we become better acquainted with the oval, larval, and chrysalidous stages), yet the differences will ever be so slight, that we cannot separate or distinguish them in the imago state with any degree of certainty. But whether they be accounted species, or only varieties, we see the grand object of their creation, in their fitness for performing certain functions which are assigned them; one of these is, to keep in check the luxuriance of vegetation and to restrain it within due limits; another may be, that these puny agents may fecundate the flowers, by carrying the fertilizing pollen from tree to tree, and thus be the means, in one case, of promoting vegetation, as in another they are the agents of its destruction.—*Hope, M. L. J. July 1840, p. 127.*

*Entomological Character of India.*—From the foregoing Analysis, I have no hesitation in asserting that the pervading character of Indian Entomology is uniformity. It is true that we meet with numerous genera, both of tropical and temperate climes, associated together; the former more abundant, the latter less frequent (as we might naturally expect) than in the Himalayas. There is, however, a greater intermingling of forms than at first sight would be readily imagined; but when we take into our consideration, that many of the species resembling those of Europe may have been captured on the mountain ranges, at a considerable elevation, we may partly account for it. This attempted explanation, however, is not always available or satisfactory; for in the heated valleys of the East, we find many European types and species, in numbers sufficient to excite our astonishment. It will appear, then, that many species taken in temperate and northern climes, are not confined to them, and that the range they enjoy is very considerable, extending not only over the Old World, but also to the New. As we advance from the Poles to the Equator, vegetation is more luxuriant, in proportion as heat increases, and the quality of work assigned to the Insect races is proportionately increased. It is not natural to imagine that the functions performed by them in a colder climate, would in a warmer one require increased exertion and capabilities? It does not follow, because we find new types of form in tropical countries, and new genera of superior bulk and power, and more abundant in individuals, that therefore they necessarily replace the old ones, and are to perform

the duties peculiar to both regions; both may live and thrive together, and abound in the same countries, and will eventually be found to do so. When the genera of temperate climes appear within the Tropics, I see no reason why they may not have the same functions assigned them there, as in colder latitudes; but when we find new types of form, and a more powerful organization, with the size of the Insects greatly increased (as is the case in tropical regions), does it not almost naturally follow that they are intended solely for those regions, and for the increase of work they are there destined to perform? To return, however, to the subject of uniformity of entomological character throughout the Peninsula and the East, I think it probable that it is in a great measure to be accounted for by the general uniformity of its temperature, vegetation, and soil; there may, indeed, be other causes, which particularly influence it, but these may be esteemed the most essential. When we look to the range which genera here enjoy, it is very considerable: in part of the Himalayas, at the extreme southern points of India, in the West, and even in its Eastern Isles, there is one prevailing character, evincing every where the prevalence of tropical genera. To speak more specifically, in Nepal and the southernmost extremity of the Mysore, and in Ceylon, at Bombay, and at Madras, at Calcutta and Singapore, in Japan and Java, with the rest of the Polynesian Isles, the majority of the same types abound; and what is of more consequence, a great majority of the same species also occur in most of the above-mentioned regions. Having noticed the intermingling of genera belonging to Europe and Asia, we may probably find a slight accordance elsewhere. Now if we turn our eyes to Africa, we shall there find a considerable similarity in the entomology of this quarter of the globe with that of Asia; and this resemblance between the two countries will be readily seen by the short annexed list of some of the more particular genera, which are common to both of them. Among the Carabidæ occur *Anthia*, *Orthogonius*, *Trigonodactyla*, and *Siagona*. Among the Lamellicornes, *Epirinus* and *Popillia*, the conical Buprestidæ and the extraordinary Paussidæ, which last are chiefly found only in these regions; and to these may be added, as well as many more, the genera *Melyris*, *Megalopus*, *Sagra*, and *Adorium*; *Dorylus*, among the Hymenoptera, and *Diopsis* among the Diptera. Passing from genera to species, we shall find that precisely the same occur in both continents; among the most conspicuous, I shall mention but a few, namely, *Copris Midas*, *Sabæus*, and *Pithecus*, *Cetonia cornuta*, and *Lytta gigas*. Even supposing that no identical species occurred, which were common to Asia and Africa, yet we could not help observing the very remarkable similarity in the representa-

tives of each; one example of which is, *Ateuchus sanctus*, which very closely resembles the celebrated Sacred Beetle of the Egyptians, the object of their worship, by some regarded as an emblem of fertility, but I think more probably that of eternity. Before concluding my remarks on the similarity of Insects found in Asia and Africa, I cannot help expressing a wish that some individual may be induced to develop the character of the entomology of these gigantic regions more thoroughly than has yet been attempted; or there is an ample field for research and speculation. We shall feel much indebted to him, if he will explain how the Copridæ were transported from one country to another, and how they reached the island of Ceylon; how also *Cetonia cornuta*, which is taken on the banks of the Gambia, became an inhabitant of India. *Lytta gigas* may have travelled by land, and perhaps the Copridæ following the tracks and droppings of the camel, may have pursued the same route. Let him describe the sands of the desert and those in the vicinity of the Indus, give us a comparative Fauna of the Ganges and the Nile, record the varieties of temperature, the character of vegetation, and the genera peculiar to the different soils. Let him do this, following the steps of the celebrated Forskal, and he indeed will advance the objects of science, deserve the thanks of the present generation, and command the respect of posterity. By pursuing the course recommended by Mr. Hope, a naturalist would be enabled, not only to display the connection between soil, temperature, and vegetation, as well as the animal forms which the latter supports, but also prove the advantages of studying the natural sciences in connection with each other, and be enabled to explain something of the laws which influence the geographical distribution of plants and animals.—J. F. R.—*Hope, M. L. J. July 1840, p. 129.*

*Descriptions of Insects, by J. O. WESTWOOD, Esq., F.L.S.*

## ORDER DERMAPTERA, LEACH.

### FAMILY FORFICULIDÆ.

#### FORFICULA MACROPYGA, Westw.

*Piceo-nigra, punctata, abdomine æneo submicante, marginibus thoracis, tegminibusque rufescentibus, forcipe (♂) longissimo valde curvato, et gracili; (♀) fere recto tenuissimo.*

*Long. Corp. (forcipe excluso) ♂ lin. 6 ♀ lin. 5.*

*Ad genus Forficulam (stricte sic dictum Servilleo) appertinet, statura fere Forficulæ auriculariæ et paullo robustior, caput nigrum punctatum, impressionibus duabus anticis inter oculos. Antennæ ♀ (♂ mutilatæ) 13-articulatæ graciles rufescentes, articulis basalibus obscurioribus. —Prothorax planus antice vix emarginatus, lateribus antice rectis, postice rotundatis, niger punctatus, margine tenui rufescenti; soveolis du-*

## ENTOMOLOGY.

abus rotundatis antice impressus.—*Tegmina* piceo-refescentia, punctata portio alarum detecta concolor. *Abdomen* nigro-piceum punctatum æneo submicans; segmento penultimo lateraliter et angulariter producto (♂) aut simplici (♀). Forceps (♂) niger valde elongatus, gracilis ad basin, valde externè curvatus, in medio, dentibus duobus parvis internis instructus, apice sursum et exterius producto, acuto (♀) elongatus multo gracilior, rufescens fere rectus et inermis.—*Westwood, M. L. J. July 1840, p. 130.*

### ORDER LEPIDOPTERA, LINN.

#### DIURNA. FAMILY PAPILIONIDÆ.

##### PAPILIO MACHAON, Linn.

This handsome butterfly, like *Vanessæ Antiopa*, and *Atalanta*, *Cynthia Cardui*, and some others, affords an instance of wide geographical range, (Messrs. Godart and Latreille, in the *Encyclopédie Méthodique* (vol. IX., Art. Papillon) state, that *Pap. Machaon* is found in Syria and Egypt.) rather than of representative structure, since the individual figured cannot be regarded as specifically distinct from the European specimens, which differ amongst themselves in various slight particulars, as the size of the dark bars, and spots, &c. It may, however, be noticed, that the specimen figured has the small oval black spot near the extremity of the anterior wings almost entirely isolated, the large basal black portion of the same wings is very strongly covered with yellow powder, whilst the black lunules of the posterior wings are not nearly so much powdered with blue bloom, as in the ordinary English specimens.—*Westwood, Hope, M. L. J. July 1840, p. 130.*

#### FAM. NYMPHALIDÆ.

##### PAPHIA PARAKEKTA, Horsfield. Lepidopt.

###### Javanica.

*Paph* alis anticis ad apicem acutis, posticis subcaudatis; anticis supra ad basin cæruleis, fascia obliqua lata fulva in medio, apiceque nigro; maculisque duabus parvis albis (una discoidali, altera apicali) ornatis; posticis cæruleis.

The preceding characters, drawn from the upper surface of the wings of this remarkable butterfly, will suffice for its determination until the publication of Dr. Horsfield's description. The under surface of the wings are, however, much more remarkable, bearing a most striking resemblance to a pale dried leaf; the deception being much increased by the form of the wings, when brought in contact by the insect, whilst sitting upon a flower in the sun-shine, the short caudal appendages giving rise to the idea of the stalk of the leaf, thus completing the delusion.—*Westwood, Hope, M. L. J. July 1840, p. 131.*

#### DIVISION? —? FAM. ZYGÆNIDÆ?

##### Genus CAMPYLOTES, Westw. ♀

Genus anomalum *Heleonæ* et *Anthonoyzæ* Sw. *Gymnanto* cæruleque *Guér*, affine, alæ oblongæ, subovales, integræ, nervis apicalibus valde curvatis, antiæ cellula discoidali clausa

## ENTOMOLOGY.

nervos duos postice emittens, quorum exterior trifurcatis, posticæ etiam cellula discoidali clausa, nervo recurrente intermedio bifurcato. Corpus parvum abdomine gracili, pone alas haud protenso. Caput parvum. Ocelli 2. Antennæ graciles biramosæ. Palpi brevissimi supra haud discernendi, maxillæ elongatæ spirales.

CAMPYLOTES HISTRIONICUS, Westw, *Æneus*, alis ad costam rufis—, interne flavo-lineatis, maculisque apicalibus albis.

Long. Corp. lin. 11; Expans. alar. unc. 3. Habitat in Nepalia. Hardwicke; in Montibus Himalayanis, Royle.

Corpus nigro æneum, palagris maculisque abdominalibus lateralibus flavis. Alæ antiæ æneæ, costa, fasciisque duabus discoidalibus rufis, fasciisque tribus internis per totam longitudinem alarum currentibus flavis; maculis 8 vel 9 (spatium inter nervos apicales occupantibus) albis. Alæ posticæ similiter coloratæ, at maculæ terminales flavo ornantur.

This remarkable insect appears to be the extreme type of a very numerous Indian group of Lepidoptera, to which belong the species named *Capys pectinicornis*, *Thallo*, and *Rhodope*. It is impossible to decide upon their real affinities, until we obtain a knowledge of the metamorphoses of some of the species.—*Westwood, M. L. J. July 1840, p. 131.*

### ORDER ORTHOPTERA. FAM. MANTIDÆ.

#### MANTIS Roylii. Hope, MSS.

### ORDER HYMENOPTERA. Section PUPIVORA.

#### FAM. CHALCIDIDÆ.

##### DIRRHINUS HIMALAYANUS, Westw.

Niger, pedibus 4 anterioribus, tarsisque posticis rufescentibus.

Capite obtuse bicornuto.

Habitat in Himalaya.

Long. corp. lin. 2. Exp. alar. lin. 3.

Caput nigrum punctatum, anticè obtusè bicornutum antennarum articulo primo nigro (articulis reliquis deteritis). Thorax fortiter punctatus; metathorace 4 lineato et ad latera, angulariter producto. Abdomen breve depressum thoracis latitudine. Pedes 4 anteriores rufescentes, 2 postici nigri, tarsi solummodo rufescentibus.

Obs. In hac specie partes oris valde elongatæ, labro oblongo-ovali ciliato, mandibulis inter se similibus, gracilibus, sub apice dente interno unico armatis.—*Westwood, M. L. J. July 1840, p. 132.*

### ORDER HETEROPTERA. Section LONGILABRES.

#### FAM. SCUTELLERIDÆ,

##### SCUTELLERA PULCHELLA, Hope, MSS.

Cæruleo-nigra vel-æneo, nitida prothoracis disco anticè, et margine postico æneo vel cupreo tincto, scutello aureo viridique intenti, fascia transversa basali, alteraque centrali obliqua, (in medio interrupta) et maculis tribus rotundatis (postice et in triangulum positis) cæruleo-nigris.

## ENTOMOLOGY.

Statura fere Scutelleræ mauræ at paullo minor, scutelloque abdomen omnino obtegenti. Scutelleræ Stockeri affinis at robustior. Antennæ articulis duobus basalibus brevibus equalibus 3tio. 2do. fere duplo longiori, ultimo omnium longissimo.

Long. corp. lin. 5. lat. lin. 3.—*Westwood, M. L. J. July 1840, p. 132.*

### FAM. PENTATOMIDÆ.

MEGARHYNCHUS TRANSVERSALIS, Westw.

Fusco-niger, capite acuté bicornuto angulisque anticis thoracis acuté antice productis, prothorace et scutello transverse striatis, parte coriacea hemelytrorum nigrâ, tenuissime punctata, membrana apicali albida, antennæ et pedes nigri.

Long. corp. lin.  $7\frac{1}{2}$ . lat. lin.  $3\frac{1}{2}$ .—*Westwood, M. L. J. July 1840, p. 132.*

ORDER HOMOPTERA. Section SALTATORIA.

### FAM. ACADIDÆ.

CICADA SULPHUREA, HOPE, MSS.

Nigra, capite thoraceque sulphureo maculatis, alarum dimidio basali sulphureo, parte anticarum sulphurea, fascia obliqua nigricanti divisa, apicibusque fuscescentibus.

Long. corp. unc.  $1\frac{1}{2}$ . Expans. alar. unc.  $3\frac{3}{4}$ .—*Westwood, M. L. J., July 1840, p. 132.*

Affinis Cicadæ maculatæ, Caput nigrum orbitu interno oculorum sulphureo; thorax niger maculis 8 sulphureis abdomen nigrum segmentorum marginibus pallidis. Alæ anticæ costâ sulphureâ, maculaque ovali maximi (plus quam dimidium basale alarum occupante) sulphurea fascia obliqua tenui nigra internè dentata divisa; apice fusco nervis nigris Alæ posticæ ad basin sulphureæ, ad apicem fuscæ nervis nigris; pedes nigri.—*Westwood, M. L. J. July 1840, p. 133.*

ORDER DIPTERA. Section PUPIFARA.

### FAM. HIPPOBOSCIDÆ.

HIPPOBOSCA MACULATA.

Thorace fusco, flavo variegato, scutello nigricanti, maculis tribus flavis, media majori, femoribus tribusque posticis ad apicem fuscis.

Hippobosca equina; "ex India orientali paullo major, thoraceque magis albo variegato, at vix distincta." *Fab. Syst. Anth. p. 338.*

Hippobosca maculata, Leach, "On the genera and species of Eproboscideous Insects." *Wernerian Trans. Vol. ii. p. 349.*

Long. corp. lin. 4. Expans. alar. lin.  $8\frac{1}{4}$ .

Caput flavum, oculis fulvis, linea longitudinali inter oculos fusca. Proboscis nigra Thorax fuscus, macula magna ad angulos anticos flavescenti in medio fusca; fascia parva centrali lunulisque duabus in medio conjunctis posticis flavescentibus, scutello nigricante maculis tribus flavis media majori. Abdomen fuscum, punctatum, marginibus rufescentibus. Pedes fulvescentes tarsis omnibus femoribus tribusque posticis ad apicem fuscis.—*Westwood, M. L. J. July 1840, p. 133.*

## ENTOMOLOGY.

### FAM. NYCTERIBIDÆ.

NYCTERIBIA ROYLII.

Obscure nigra pedibus fuscescentibus elongatis, vix compressis, coxis anticis brevibus, abdomine ovalo, conico, depresso, 5-articulato, apice subtruncato, stylis duobus incurvis subtus armato, capite compresso.

Long. corp. lin.  $1\frac{1}{3}$ .

Habitat in India Orientali.

Nyct. Roylei. Westw. in *Trans. Zool. Soc. 1, p. 290-5.*—*Westwood, M. L. J. July 1840 p. 133.*

### ORDER COLEOPTERA.

CETONIA ROYLII, Hope.

Long. lin. 12 lat. Lin. 6.

Nigro-viridis thorace flavo marginato elytris-que quatuor maculis flavis notatis. Clypeus quadratus. Antennæ nigræ. Caput quadratum punctatum. Thorax cupreis marginibus externis elevatis, lineaque flava utrinque externa, disco fortissime punctato. Scutellum magnum postice decitum. Elytra nigro-virescentia maculis quatuor flavis notata, binæ fere rotundatæ ad basin positæ, binæ aliæ reniformes ante apicem lacatæ. Corpus infra nigro-æneum segmentis abdominis utrinque aurantiis capillis obsitis pedibusque concoloribus.

In Mus. Dom. Royle; in montibus Himalayæ captus ceria.—*Westwood, M. L. J. July 1840, p. 134.*

GEOTRUPES ORIENTALIS.

Long. lin. 10. lat. lin.  $6\frac{1}{2}$ .

Violaceus thorace sparsim punctulato, elytris striatopunctatis, pedibus supra nigris, infra violaceis nitidis. Antennæ piceæ capitulo fuscanti, thorax violaceus longitudinali serie punctorum in medio positi, variis aliis sparsim dispositis. Elytra striato punctata striis quasi vermibus erosis. Corpus infra violaceum nitidum, femoribus posticis uni-spinosis, tibiis pilosis, tarsis chelis-que piceis.

This singular species approaches very closely to some of the British species, and is probably from a high elevation of the Himalayan mountains.

In Mus. Dom. Royle.—*Westwood, M. L. J. July 1840, p. 134.*

ONTHOPHAGUS PHANÆOIDES.

Long. lin.  $4\frac{1}{2}$ . lat. lin.  $2\frac{1}{4}$ .

Niger obscurus, clypeo cornu reflexo abrupte truncato, thorace phanæoformi, postice lateribus, in spinam obtusam productis, femoribus luteis. Antennæ piceæ capitulo fuscanti: clypeus hexagonus cornu reverso abrupte truncato, thorax fere quadratus; punctatissimus, punctulis erosis tuberculo antice, fossulaque postice in medio marginis impressa, angulis posticis in spinas productis. Scutellum parvum nitidum. Elytra striata. Corpus subtus atrum nitidum punctatum. Pedes femoribus luteis, tibiis tarsisque nigropiceis.

This singular Insect will, at some future period,

## ENTOMOLOGY.

form the type of a new genus : in form it unites the South American *Phanæus*, and the widely-disseminated genus *Onthophagus*.—*Westwood, M. L. J. July 1840, p. 134.*

**LUCANUS LUNIFER.**

Long. lin. 37. lat. lin. 10.

*Æneo-piceas, areolo tomento aspersus, mandibulis exsertis unidentatis, denticulisque minoribus instructis, apice bifurcatis. Clypeo deflexo lunifero, femoribus castaneis.*

Hab. in Montibus Himalayæ; in Mus. Dom. Royle.

This Insect appears to unite in itself the characters of the Asiatic and European species, the latter rather predominating over the former: it is one of the finest forms of the Himalayan Fauna.—*Westwood, M. L. J. July 1841, p. 135.*

**LAMIA WALLICHII.**

Long. lin. 16. lat. lin. 5.

*Viridisericeus, antennis penicillatis, elytris tribus fasciis nigris, binisque penicillis dosalibus ornatis. Antennæ corpore longiores et nigro-virides, primo articulo subpenicillato, tribus sequentibus atris, penicillis magnis pilorum barbatis, et reliquis pubescentibus, ultimo tamen pubescentia densiori tecto. Thorax viridis, spinosus. Elytra ornata tribus fasciis vix suturam attingentibus, una in medio elytrorum, secunda inter mediam et apicem, tertiaque binis penicillis dorsalibus interrupta. Corpus subtus nigro-virens, sanguinea pubescentia aspersum. Segmenta quatuor abdominis sanguineo colore fucata, ultimum omne autem viride et nitidum. Pedes viridi-pubescentes, femoribus macula rufa notatis tarsisque infra flavis.*

It is impossible to describe accurately the beauty of this Insect; the sericeous covering, in different lights, imitating the various tints of opal, while the dark fasciæ flash with the iridescence of Labrador felspar.—*Westwood, M. L. J. July 1840, p. 125.*

**PORUS, Hope.**

{**STENIDÆ, ML.**

{**LONGIPALPI, Lat.**

*Corpus oblongum fere parallelum subdepressum. Caput mediocre oculis magnis lateralibus. Antennæ crassæ articulis transversis. Mandibulæ acutæ dente interiori armatæ. Labrum transversum integrum ciliatum. Maxillæ elongatæ bilobatæ. Palpi maxillares longitudine mediocres articulo 3tio. longo clavato, ultimo minimo. Labium elongatum apice lanceolato, paraglossis lateralibus. Palpi labiales breves, articulo ultimo parvo conico. Thorax fere circularis. Abdomen elongatum marginatum. Pedes simplices. Tibiæ calcaribus binis armatæ. Tarsis articulis simplicibus.*

**PORUS OCHRACEUS.** Long. lin. 4. lat. lin.  $\frac{3}{4}$ .

*Elytris punctatis antennis fuscis, mandibulisque ad apicem nigris.*

Hab. in Montibus Himalayæ; in Mus. Dom. Royle.

## ENTOMOLOGY.

This genus somewhat approaches the European *Evræsthetus*.—*Westwood, M. L. J. July 1840, p. 135.*

**APHODIUS.**

**APHODIUS IRREGULARIS, Hope.**

Long. lin. 4. lat. lin. 2.

*Flavus thorace nigro, elytris subaurantiis, fascia media maculis quatuor nigris, pedibusque piceis. Antennæ piceocapitulo fusco. Caput angulis anticis oblique truncatis. Thorax niger nitidus punctatus, angulis anterioribus flavis. Elytra flava, seu subaurantia, fascia media irregulari nigra, binis maculis humeralibus binisque aliis fere ad apicem locatis concoloribus.*

Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood, M. L. J. July 1840, p. 136.*

**ANISOTELUS, Hope:**

**TELEPHORIDÆ.**

*Antennæ articulo Ino. crasso, reliquis multo crassiori, 9-10 obconices magnitudine paululum crescentibus ultimo majori ovato apice acuto. Mandibulæ valde acutæ. Maxillæ membranaceæ lobo unico intus tomentoso. Palpi articulo 1mo. minimo, 2do. et quarto æqualibus, ultimo subsecuriforme. Mentum transversum. Labrum membranaceum fere rotundatum. Palpi labiales breves, articulo ultimo majori securiformi. Caput transversum oculis prominalis. Thorax transversus lateribus rotundatis, angulis posticis acutis elevatis. Elytra sicut in *Telephoris*, in medio nonnihil dilatata. Tarsi 5-articulati, articulo penultimo bilobato.—*Westwood, M. L. J. July 1860, p. 176.**

**ANISOTELUS BIMACULATUS, Hope.**

Long. lin.  $4\frac{1}{2}$ , lat. lin. 2.

*Lividus, elytris 2-maculatis. Antennæ articulo primo testaceo, reliquis fuscis. Thorax rufo-testaceus nitidus, elytris pallidioribus macula ovali nigra in singulo fere ad apicem posita. Corpus in fra testaceum.*

Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood, M. L. J. July 1840.*

**ELATER CYANOPTERUS, Hope.**

Long. lin.  $4\frac{1}{2}$ , lat. lin.  $1\frac{1}{4}$ .

*Cyaneus, antennis fuscis, marginibus thoracis pedibusque rubris. Caput nigrum antennis fuscis. Thorax in medio nigro-cyaneus, marginibus lateralibus rubris. Elytra striato-punctata subpubescentia. Pedes rubris.*

Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood, M. L. J. July 1840, p. 196.*

**RIPIPHORUS APICALIS.**

Long. lin. 3., lat. lin. 1.

*Rufus, thorace pedibusque nigris, elytris flavo-rufus quatuor maculis notatis. Caput atrum ramo antennarum piceo, foliisque nigris. Thorax concolor. Elytra flavo-rufa, basi nigrofasciata, maculis binis fere mediis, apicibusque cor-*

## EUPHORBIA NETILFOLIA.

poreque infra nigris. Hab. in Montibus Himalayæ, in Mus. Dom. Royle. — *Royle's Illustrations of the Botany, &c. of the Himalayan Mountains, and Supplementary Part by Westwood, quoted in M. L. J. July 1840, p. 137.*

(734) ERUPUNA in Tamil, EREMBURAPAN in Malayala. This tree is of a dark brown colour, with a yellow tinge, and in texture resembles the marda; it is heavy and strong, grows to about fifteen inches in diameter, and from fifteen to eighteen feet long. It produces a small black fruit which is of no use. The natives prefer it to other woods for rice-beaters, from its weight and texture. — *Edye. M. and C.*

(735) ERYTHRINA INDICA. Is conspicuous from its bright scarlet flowers. — *Wight's Ill. In. Botany, Vol. I. p. 192.*

(736) ERZROOM. Erzroom is the Capital of the Pashalic which bears the same name, and is about ten days journey from the Persian frontier. It is built on an elevated plain about 6000 feet above the level of the sea. The cold there is intense, and lasts usually from September till May. Lying on the high road from Persia to Constantinople, it is the resort of many merchants and caravans, but it has not recovered the Russian occupation in 1829, when its fortifications were dismantled, and many of its most opulent and industrious inhabitants, the Armenians, were induced to emigrate. One of the branches of the Euphrates flows at a short distance below the city.

(737) EUGENIA RACEMOSA. Lin. — CLUSTERING EUGENIA.

### The Root.

Cadapum vayr, TAM.		Root of the Cluster-
Kanite vayroo, TEL.		ing Eugenia.
		Neepa, SANS.

This root has a slightly bitter taste, and is considered by the Native Practitioners as a valuable medicine on account of its aperient, deobstruent, and cooling qualities, it is given in decoction. The seeds and bark are also employed, the latter which is of a reddish colour, is said to possess virtues similar to those of our Cinchona. — *Ainslie's Mat. Med. p. 75.*

(738) EUPHORBIA. In China, many plants are cultivated for their oil, to be used in the arts as well as cooking; a strong oil is derived from the seeds of two or three plants belonging to the Euphorbiaceous family, for mixing with paint, smearing boats, &c. It is deleterious when taken into the system, but does not appear to injure those who use or express it. — *Williams' Middle Kingdom, p. 107.*

(739) EUPHORBIA NETILFOLIA. Lin. Oleander leaved spurge.

Elekullie, (TAM.)		Akoojimoodoo, (TEL.)
Putteoon ke saynd, (DUK.)		Puttrakarie, also Seej,
Vurki zukkoom, (ARAB.)		(SANS.)

This tree grows to a good height, differing in

## EXACUM BICOLOR.

that respect from Shuddraycullie and Tirugkocullie, and it would appear to have got its Tamool name from having leaves of considerable size, which neither of the other have, they are of a yellow green colour.

The white juice of this species of Euphorbium the Native practitioners prescribe internally, as a purge and deobstruent, in those visceral obstructions and dropsical affections which are consequent of intermittent fever. It is also, when mixed with margosa oil, used as an external application, in such cases of contracted Limb as are brought on by ill-treated Rheumatism.

This plant is the Daun Sudu Sudu of the Malays. The Javanese, Rumphius tells us, consider the young leaves as stomachic. — *Ainslie's Mat. Med. p. 79.*

(740) EUPHORBIA TIRUCALLI.

Kulli (Milk hedge.) TAM.

Dr. Wight has never seen the wood of this used, but often heard it spoken of as excellent for gun stocks. To him it seemed too light coloured.

(741) EUSPIZA STEWARTI, Bligh, affined to E. cæsia (Cretsch.) Length about  $5\frac{1}{2}$ ; of wing 3 to  $3\frac{1}{4}$  in.; and tail  $2\frac{1}{2}$  in. Crown and front of neck ashy; the ear-coverts and upper-parts of breast albescent-ashy; throat and supercilia black, the feathers of the former margined with whitish towards the chin; lower half of breast, flanks partly, nape, back, rump, upper tail-coverts, and fore-part of wings, deep-ferruginous approaching to maroon, the feathers more or less bordered paler; rest of wings dusky, the feathers margined with brown; and belly and lower tail-coverts buffy-white; tail having its outermost feather  $\frac{2}{3}$  white, and the next  $\frac{1}{2}$  white. A younger male, or seemingly shot earlier in the breeding season, has the fore-part of the wing less rufous, the pale margins to the feathers generally rather more developed, and slight central dusky spots on those of the back. — *Bengal As. Soc. Jo. p. 215, No. 2 of 1854.*

(742) EXACUM BICOLOR, ROXB. *Wight Ic. Pl. Ind. Ort. 1321.*

Stem 4 angled, leaves sessile ovate subacute 3-5 nerved with smooth margins, calyx deeply 4 cleft segments subulate with ovato lanceolate wings corolla white tipped with blue lobes elliptic oblong cuspidate three times longer than the tube which is a little shorter than the calyx. Corolla large, nearly two inches in diameter, cymes terminal subcontracted middle internodes usually shorter than the leaves. Griseb in Decandolle, Prod. J. P. 45. Neilgherries below Kotagherry rare in pastures; about a mile below Nedawuttim abundant flowering during the autumnal months. This plant is well figured in Wight's Specilegium Neilgherrense t. 108 Cuttack Roxburgh, Neilgherries Baron Hugel, Malabar Ghauts Cleghorn. A bundle of the dried stalks of this plant was forwarded to the Madras Exhibi-

## FELINE ANIMALS OF INDIA.

tion of 1855 from Mangalore marked "Country Creyat, price one anna six pie per lb." The name shows that it is used as a substitute for Creyat (*Andrographis paniculata*). In this species, which enamels the sword of the Western Ghats with its beautiful blossoms, the same bitter stomachic

## FELINE ANIMALS OF INDIA.

qualities occur, for which the *Gentiana* is so much employed, and I believe that it may be used with advantage for medicinal purposes as a substitute for Creyat, (*Andrographis paniculata*). —*Ind. An. Med. Science*, p. 270.

## F.

(743) **FAQEERS**, or *Durvesh*, religious mendicants amongst the Mahomedans of whom there are several sects.

In India, this Class of religious devotees are generally

1 The Kadriah or Banuwa	5 Mulling.
2 The Chistee.	6 Rufae or Goorzar.
3 The Shootareea.	7 Jullallea.
4 Tubqateea or Mudareea, also called duffalee.	8 Sahageea,
	9 Naqsh-bundeea.
	10 Bawa peearay.

The Calendar *durvesh* is only rarely seen in India.

(744) **FATEEHAN**, ARAB, prayers offered in the name of Mahomed.

## (745) FELINE ANIMALS OF INDIA.

**ASIATIC LIONS.** In India, there are a considerable variety of animals which are called "Cats" in different countries, and thus we hear of *Civet-cats*, *Genet-cats*, *Marten-cats*, *Pole-cats*, &c.; the Lemurs or *Madagascar Cats*; and the marsupial animals which are known as "wild cats" in Australia, to say nought of the *Shir-mindi billi* of the Bengalis. The "Wild Cats" are a small but savage kind of *Lynx* (the *FELIS RUFA*), and therefore a true Cat. *Bonafide* Cats are very numerous in species, and are of all sizes, from the Lion and Tiger downwards. The Feline tribe, inhabit most countries, and are nowhere more abundant in species than in India and its environs, from the snow-capped Himalaya to Ceylon inclusive, and along the eastern side of the Bay of Bengal and Malacca Straits. Throughout this range of territory we have them of all sizes, from the largest to the smallest; and appertaining to various subdivisions of the great genus *FELIS*. These subdivisions or minor groups, however, have not been satisfactorily established: and one great authority, Professor Temminck of Leyden, gave up in despair the attempt to classify the long series of feline animals otherwise than in order of size. It needs no extraordinary acumen to recognise the type of one sub-group in the Lion, of another in the Tiger, of a third in the Lynxes

ing Leopards or *Cheetas* of books on natural history, and so on; but there are various species which do not conform to any such division, nor possess sufficiently marked characters to stand as the types of peculiar divisions: again, there are local groups; thus among the animals generally classed as Leopards, there is the South American type, with large bull-dog head and comparatively short tail, to which the Jaguar and Ocelots belong,—and also the Asiatic type with very long and thickly clad tail, large body-markings, &c., to which the Ounce or ('Snow Leopard') and several other and smaller animals appertain. It is scarcely worth while here to enter learnedly into this matter; the object of the present communication being rather to discriminate the various feline animals which may happen to fall under the notice of an Indian sportsman.

1. The Lion, *FELIS LEO*; considered by some naturalists as a sub-genus *LEO*, comprising a plurality of species. The Lion, as everybody knows, is the desert king; as the Tiger is monarch of the jungles. Hence, as an Indian animal, he belongs to the N. W. Provinces, from which he is very fast disappearing. In the Honorable Mountstuart Elphinstone's *Account of the Kingdom of Cabul*, which was published in 1815, it is remarked, that—"The Lion, though so common in Persia, and lately found in such numbers in Guzerat and in the *Hurriana*, North-West of Delhi, is very rare in Afghanistan." As regards the latter country, he adds,—“The only place where I have heard of Lions, is in the hilly country about Cabul, and there they are small and weak, compared to the African Lion. I even doubt whether they are Lions.” Lieut. Irwin, who accompanied Elphinstone in his Mission to Cabul, states, in his admirable *Memoir on Afghanistan*, long subsequently published by the Asiatic Society (in 1839), that—"The Lion is a native of Persia, and some are found as far as Tashkund, in a northerly direction and an easterly. There remains no doubt of Lions being found in Hurriana; but in many of the intermediate countries these animals are very rare." These notices are contemporaneous; and one certainly conveys

## FELINE ANIMALS OF INDIA.

animal in the great Hurriana desert than the other does: but it has long since been extirminated in that quarter. So far back as in 1837, the late well known sportsman Major Brown, ('Gunga' of the *Bengal Sporting Magazine*) remarked, that—"Only twenty-three years elapsed from the occupation of the country, when the Lions, which were at one time numerous in the dry and sandy deserts of the Hurriana, became extinct south of the Cuggar, through the ardour of British sportsmen, and, it is supposed, none are now to be found nearer than the Sutlej. Having no inaccessible dens to retire to during the hot weather, the Lions, from necessity, took up their abode where water could be found; and as places of this description were rare, and generally near villages, their retreat was easily beaten up, and their entire destruction speedily effected. In the month of May, the Lion-shooting party had only to ask one question from the people of the country, to know whither they might expect sport?" (i. e. where water was still to be found.) \* \* \* "The largest Lion at present in England was caught, when very young, in Hurriana, by Genl. Watson, and was presented to his late Majesty, Geo. IV." In Vol. 1 of the *Sporting Review*, the Lion is cursorily mentioned as an inhabitant of the territories south of Gwalior in 1845: About eight or ten years ago, (about 1848) there was seen in Calcutta a fine living Lioness, more than two-thirds grown, which had been captured as a small cub in Sindh. She appeared healthy and vigorous; but died in the course of her passage to England. There are also, now, in the London Zoological Gardens, a young Lion and Lioness from Guzerat; which is the stronghold of Leo in this country.

From the accounts of Asiatic Lions, there seem two distinct races of them: one comparatively maneless; the other heavily maned, scarcely (if at all) less so than the African Lion. Of the latter, again, some naturalists distinguish apart the Lions of Barbary, Senegal, and South Africa:

The ordinary Persian Lion is well maned; and this race is said to be identical with the Arabian. A fine Persian Lion and Lioness were long exhibited in the Surrey Zoological Gardens, with a fine S. African Lion and Lioness in an adjoining den; and, to the best of Mr. Bligh's recollection, (and I have seen them often,) "there was not much difference in the development of the mane of those two Lions; but the Persian was a much paler animal than the other." According to Mr. Warwick, "the pair were brought as a present to his late Majesty, George IV., from Bussora, in the *Boyne*, man-of-war, Captain Campbell, who presented them to the Menagerie then at Exeter Change. The Asiatic," he adds, "differs from the South African Lion in being rather less in size, with mane much more scanty, and of a light yellow colour, tipped with

## FELINE ANIMALS OF INDIA.

colour. The head wants the width and nobleness of countenance so apparent in the African Lion. The animal falls off towards the withers more than in the African Lion; the tail is not so delicately tapering, and the tuft at the end of it is much larger in proportion." Naturalist's Library.—*Felineæ*. The above description having been taken from the living beast, with a living African Lion beside it for comparison, must be supposed tolerably correct, so far at least as concerns that particular specimen; but it nevertheless does not accord with my recollection of the identical individual, perhaps from the season at which it was taken; or perhaps the animal was older when I saw it. For I have a very strong impression that the mane was considerably heavier than would be inferred from Mr. Warwick's notice of it, and that the creature was not smaller than its African neighbour. At the same time was exhibited a large emasculated Lion, which was quite maneless, and resembled an enormous fat and lazy Lioness.

The late well known and distinguished sportsman, Major Sir W. Cornwallis Harris, had no faith in the existence of an Asiatic race of maneless or scantily-maned Lions: and be it remembered that he was as familiar with the Lion of Guzerat as with that of South Africa. His very decided opinion on the subject is thus expressed in the letter-press accompanying his *Portraits of the Game and Wild Animals of South Africa*.—"In point of size and complexion the South African Lion differs in no respect from that found so abundantly in Guzerat—one of the only two provinces of India wherein the species exists—measuring usually between ten and eleven feet in extreme length (i. e. the stretched skin!), "and varying in hue betwixt ash-colour and tawny-dun; but generally possessing a more elaborate and matted mane; which peculiarity is attributable, in a great measure, to the less jungly character of the country that he infests, and to the more advanced age to which, from the comparatively small number of his mortal foes, he is suffered to attain. In India the Lion is often compelled to establish himself in heavy jungles, which comb out a considerable portion of the long loose silky hairs about his head and neck; but this is seldom the case in the arid plains of Africa, where the covert being chiefly restricted to the banks of rivers, or to isolated springs, he rests satisfied with a less impervious shade, and is often disturbed from a clump of rushes, barely large enough to conceal his portly figure." Elsewhere, Major Harris remarks, that—"Amongst the Cape colonists it is a fashionable belief, that there are two distinct species of the African Lion, which they designate the *vaal* and the *zwart*, or the "yellow" and the "black," maintaining stoutly that the one is very much less ferocious than the other:

## FELINE ANIMALS OF INDIA.

reader, that both the colour and the size depend chiefly on the animal's age; the development of the physical powers, and of the mane also, being principally influenced by a like contingency. That which has been designated the "maneless Lion of Guzerat" is nothing more than a young Lion whose mane has not shot forth; and I give this opinion with less hesitation, having slain the king of beasts in every stage from whelphood to imbecility."

The so called maneless Lion of Guzerat was brought to the notice of the London Zoological Society by Capt. Walter Smee, of the Bombay Army, in 1833: and an excellent description and coloured figure of it are published in the first volume of the Society's *Transactions*, contributed by that officer. The skins of a Lion and Lioness killed by himself in Guzerat, and presented by him to the Society, were selected from eleven, obtained there by him, eight of which he took to England. "This Lion," he remarks, "is distinguished from those previously known, by the absence of a mane (that is, he is maneless as compared with other Lions,) from the sides of the neck and shoulders; the middle line of the back and neck being alone furnished with longer hairs, which are erect, like those in the same situation in the Hunting Leopard (*Felis jubata*). The under surface of the neck has long loose silky hairs, and there is a tuft at the angle of the fore-legs. Besides the absence of the extensive mane, the tail is shorter than that of ordinary Lions, and is furnished at its tip with a much larger brush or tuft." Capt. Smee's description is too elaborate for quotation here, but he asserts that "in none of his eleven specimens was the mane more extensive than in the male exhibited; and in none of them was it in any degree pendent. A male measured 8 feet 9½ inches in total length, including the tail: its height was 8 feet 6 inches. A female killed at the same time was 8 feet 7 inches long, and 3 feet 4 inches high. The impression made by the paw of the male on the sand measured 9½ inches across. His weight, exclusive of the entrails, was 35 stone of 14-lb. to the stone.

"These Lions," continues Capt. Smee, "are found in Guzerat along the banks of the Sombermuttee, near Ahmedabad. During the hot months, they inhabit the low bushy wooded plains that skirt the Bhardar and Sombermuttee rivers from Ahmedabad to the borders of Cutch, being driven out of the large adjoining tracts of high grass-jungle (*Bhirs*) by the practice annually resorted to by the natives of setting fire to the grass, in order to clear it and ensure a succession of young shoots for the food of the cattle upon the first fall of the rains. They extend through a range of country about forty miles in length, including various villages, and among others those of Booroo and Goliana, near which

## FELINE ANIMALS OF INDIA.

common in this district, that I killed no fewer than eleven during a residence of about a month; yet scarcely any of the natives, except the cattle-keepers, had seen them previously to my coming among them. The cattle were frequently carried off or destroyed, but this they attributed to Tigers: the Tiger, however, does not exist in that part of the country. Those natives to whom they were known gave them the name of *Ontiah Bagh*, or 'Camel Tiger,' an appellation derived from their resemblance in colour to the Camel. They appear to be very destructive to domestic cattle, and the remains of a considerable number of carcasses of bullocks were found near the place at which my specimens were killed: about ten days previously, four donkeys had been destroyed at the village of Cashwa. I could not learn that men had ever been attacked by them. When struck by a ball, they exhibited great boldness, standing as if preparing to resist their pursuers, and then going off slowly and in a very sullen manner; unlike the Tiger, which, on such occasions, retreats springing and snarling.

"In addition to the district in which I have met with them, these Lions are also found on the Rhun near Rhunpore, and near Puttun in Guzerat. Some persons who saw them in Bombay stated that they also occur in Sind and in Persia. How far this latter statement may be correct I cannot determine; but I may remark that the Persian Lion that is at present exhibited at the Surrey Zoological Garden, has none of the characteristics of the maneless Lion of Guzerat, and seems to me to differ but little from individuals known to have been brought from Africa."

In the days of Lord Hastings's rule, it would appear that Lions were common in the great Hurriana plain. A contributor to the *B. S. M.*, in 1833, remarks that "Hansi was then in its 'high and palmy state,' and considered the best sporting country in India. Lions were found in considerable numbers, although lately they have become exceedingly rare. \* \* \* The first Lion-hunt I ever was present at was the most beautiful sight I have witnessed. The party assembled at Hissar, where some of the sporting elephants of the Marquis of Hastings's retinue were stationed. A duffedar's party, of Skinner's Horse, accompanied us. The presence of sowars in Lion-hunting is very necessary; the plains being extensive, the animal is liable to be lost after the first onset, unless sowars are at hand to go out on the flanks, or to push on ahead to mark the jungle the lion retires into. In general, when a Lion is pursued, he will either endeavour to get away by sneaking off, or take to the open country, and there await the attack: the latter, a Tiger is never known to do, and I consider it to form the only peculiar difference of the two kinds of

## FELINE ANIMALS OF INDIA.

gives more exciting sport by far than anything I have seen in Tiger-hunting, and is the most trying for the elephants. \* \* \*

One killed was a young but nearly full-grown male stood exactly 3 ft. high, and was 9 ft. long; *his mane was 9 inches in length*" The famous Lion 'King George,' formerly in the Tower-menagerie, and procured in *Hurriana* when a small cub by the late Genl. Watson, was even renowned for the superb development of his mane! Now for the Lion of Kattywar or central Guzerat. In the *B. S. M.* for July, 1840, is a record of one there slain, of which we read:—"This Lion was 9 feet, *with a flowing mane*, and altogether much more bulky than any Tiger I have killed: although many have measured upwards of 11 feet in length" (which of course means *the stretched skin*). Capt. Smee distinctly states, on the contrary, that the Lion of Guzerat is "destitute of the flowing mane," and that in none that he examined "was it in any degree pendent." Again, in the *Bengal Quarterly Sporting Magazine*, 1., 357 (1844), we read of "a large-maned blackish Lion" in Kattywar.

As regards the comparative size of the Lion and Tiger, I suspect that no Lion, even in Africa, attains to the magnitude of our largest male Tigers: but they are differently-made beasts, as seen by a glance at their skeletons. The Lion is shorter in the vertebral column, and much deeper in the chest; indicative of its capacity for running in pursuit: this the Tiger never does; and its structure is more emphatically that of an animal which springs upon its prey. Nevertheless, the resemblance of the skulls is so great, that there is only one certain mode of distinguishing them, viz, that the nasal bones pass back beyond the maxillaries in the Tiger-skull, and fall short of the maxillary suture in the Lion-skull: besides which the profile of the latter is generally much straighter, while that of the former is more tom-cat like, showing a strongly marked obtuse angle. The close affinity of the two animals is demonstrated by the fact of their having interbred and produced hybrids when in captivity; and it is curious that a newly-born Lion-cub is far from being so utterly unlike a Tiger-cub as might have been expected. "They are at first obscurely striped or brindled, and somewhat Tiger-like in the coat. There is generally a blackish stripe extending along the back, from which numerous other bands of the same colour branch off, nearly parallel to each other, on the sides to the tail. The head and limbs are generally obscurely spotted. When young they mew like a Cat; as they advance, the uniform colour is gradually assumed; and at the age of ten or twelve months the mane begins to appear in the males; at the age of eighteen months this appendage is considerably developed, and they begin to roar." (Bennett's

## FELINE ANIMALS OF INDIA.

states that it is nearly the third year before the mane and the tuft on the tail appear, and that they are not fully developed before the seventh or eighth year. The eminent French naturalist was misinformed. The so-called Bengal Lion (from *Hurriana*) figured by Mr. Bennet was magnificently maned, though little more than five years old. I have noticed, too, that in Lionesses the markings of the young are often more or less obscurely retained till they are full-grown or nearly so. They were conspicuously visible in the Sindh Lioness, about two-thirds grown, which I saw in Calcutta. Lion and Tiger-cubs are, in confinement, apt to suffer much at the time of developing their huge permanent canine-teeth; and perhaps many die at this age when wild. To this cause was attributed the loss of the two litters produced in England of Lion-tiger hybrids. As regards the age to which these animals attain, 'Pompey,' the great Lion which died in 1760, was said to have been in the Tower of London above seventy years; and one from the river Gambia is stated to have ~~stare~~ died there at the age of sixty-three. A neerological table of statistics relative to the length of life of the animals at the Jardin des Plantes, contains the following:—"The average length of life of the Lion, Tiger, and Panther, in a menagerie at Paris, is six or seven years. A Lion, however, has lived 29, and a Lioness 17. Lions, which are carried about and exhibited to the public, are found to live much longer, generally from 17 to 20 years." Major Harris met with an aged wild African Lion, in almost the last stage of decrepitude. He was in company with others of his species, who may have helped to provide for him; for Lions are highly social, if not gregarious, and this one may well have lived on the superabundance of his companions' slaying. Of the venerable beast, he writes,—"There is much repose and grandeur about the mortal remains of Leo, and I never recollect to have seen the asserted resemblance to the human face divine, more perfectly preserved than in this subject, already in the last stage of imbecility. Years had robbed him of his pristine vigour, and the honorable scars of many a fierce conflict seared his scabby hide. His once splendid mane had waxed scant and scraggy, his yellow fangs were worn away to their stumps, and so deeply had age furrowed his savage cheek, that with his overhanging brow and bearded under-jaw, he might have furnished a handsome portrait for a toothless Jew." Those who have only seen and studied these animals in menageries, cannot fail to have remarked the calm and majestic expression of the Lion's countenance, as contrasted with the bestial visage of the Tiger! No contrast can be more striking; nor are the physiognomies altogether deceptive. The Lion's eye recalls to mind the human,—the Tiger's is

nine out of ten sportsmen will affirm) the vertical pupils of a Cat; neither has the Leopard's.

A correspondent of the *B. S. M.* (for 1841,) thus writes of the Lions of Kattywar:—"Glad as I should be to agree with so accomplished a sportsman as Capt. Harris, and knowing at the time I write this, that he has killed more Lions than any man on this (the Western) side of India, yet having nearly accomplished fifty head myself, I wish modestly to observe that there were, three years ago, in Kattywar, Lions with very dark skins, and which in fact were called by the natives *Kalphoota*, which means in these parts 'black skin,' or 'black stripe.' These said Lions, thirteen in number, charged most desperately; and I think they made good some seven or eight charges upon the head of Capt. Harris's quondam elephant, 'Mowlah' by name. Since this batch I have killed many, but none in colour or courage like them: their skins were sent to a friend of mine in Bombay two years ago, who was formerly in one of our cavalry regiments, and is at present a well-known capitalist! and besides, out of all the Lions I have killed, 9 feet 2 inches is the longest I have seen. Before taking the skins off for curing, they are stretched to 11 feet frequently. I merely mention this fact to prove (!) that the breed is degenerating; or that Capt. Harris, who hunted this country some years before me, must have had the cream of the feline." I believe that this gentleman gives the correct measurement of the animal, as distinguished from that of its stretched skin; and he supplies a list of twenty Lions and Lionesses killed (by himself?) in Kattywar, during 1840 and 1841.

So far as I can learn, the breed seems now to be completely exterminated throughout the Hurriana desert, and in Sindh and the adjacent districts of the Punjaub. Can any of your contributors supply information on the subject? And is this grand animal to be utterly extirpated even in Guzerat, without so much as a museum specimen having been preserved to shew what a maned Indian Lion was like? The few that remain to fall by the sportsman's gun should now at least be carefully preserved, both skin and skull, and the museums of the different Presidencies, of the India House and others, be supplied with specimens. Even in Kattywar, the race must surely be fast diminishing in numbers and verging towards extinction? Can any reader inform us of the number of Lions slaughtered there during the last few years?

\* Mr. Bennett (in his *Tower Menagerie*) relates that in the commencement of year 1823, the late "General Weston, then in service in Bengal" (he should have said Hurriana,) being out one morning on horseback, armed with a double-barrelled rifle, was suddenly surprised by a large Lion, which bounded out upon him from the

He instantly fired, and the shot taking complete effect, the animal fell dead almost at his feet. No sooner had the Lion fallen than the Lioness rushed out, which the General also shot at, and wounded severely, so that she retired into the thicket. Thinking that the den could not be far distant, he traced her to her retreat, and there despatched her; and in the den were found two beautiful cubs, a male and female, apparently not more than three days old. These the General brought away: they were suckled by a goat and sent to England, where they arrived in September, 1823, as a present to George IV., and were lodged in the Tower." The male was the animal from which Mr. Bennett gives his figure and description of the so-called "Bengal Lion;" and he was remarkable for *the superb development of his mane*, when little more than five years old, at which age the wood-cut of him was executed by Hervey. In Moorcroft's Narrative of his "Journey to Lake Manasarowara," published in the '*Asiatic Researches*,' Vol. XII., p. 512, the following curious passage occurs:—"We were told that on the summits of the neighbouring mountains there was a large red tiger, which feeds on elks and the largest kind of game, but seldom comes to the lower part of the country. He is described to be of the size of a small horse [in a land of ponies], his neck is covered with hair so long as to fall over his face and almost conceal his head, as he comes down hill. From this account it is presumable that the animal is a lion." Not very likely.

The sum of our present evidence seems decidedly adverse to the belief that a maneless (or comparatively maneless) race of Lions exists in Guzerat: but that such a race inhabits Mesopotamia is considerably more probable; and the question should be settled by transmitting live specimens of this alleged maneless race to Europe, which in time would develop as fine a mane in captivity as when wild, should their nature permit of the adornment. Witness the Hurriana cub sent to England by the late Genl. Watson. What was done with this fine Lion after death I know not, but he surely should have been made over to the British Museum.—*Mr. Bligh in Ben. Sp. M.*

This wild species approximates very nearly to the domestic Cat. The ground colour of the fur is a "Cat Gray," more or less fulvescent or better described as pale grayish-fulvous in some speci-

## FELINE ANIMALS OF INDIA.

tend to unite into transverse bands on the sides : on the head, nape and shoulders, the spots are smaller and less distinct, and tend to form longitudinal lines on the occiput and nape, but not upon the back. On the limbs there are distinct cross bands, with one or two broad black streaks within the arm, as in the Chaus and commonly in domestic cats; the paws blackish underneath: cheek-stripes as usual, breast spotted, but the belly almost free from spots: tail tapering more or less distinctly, and marked with a series of well defined rings and a black tip: ears externally dull rufous, with a slight but distinct duskyish pencil tuft at tip, not black tipped as in the Chaus, nor is their rufous colour nearly so bright as in that animal, differing little from the general hue of the body: the fur according to locality or perhaps season is more or less dense or full; and the markings are much brighter and more distinct in some individuals than in others.—*Jour. As. Soc. of Beng. November, 1856, p. 441.*

Of two supposed wild types of the domestic Cats of India, obtained by Mr. Theobald in the Punjab Salt Range (two specimens of each of them,) neither can be referred to the *F. ornata*: they have much more the appearance of domestic cats; and so they undoubtedly would have, were they really two aboriginal types which are still strongly indicated by the domestic cats even of Bengal. One is the streaked or spotted type, the colouring and markings of which are not much unlike those of the European wild cat (*F. Sylvestris*, Brisson); only more distinct, and the transverse streaks are more broken into spots, especially towards the hinder part of the body; the fur, however, is short, and the tail slender and of uniform apparent thickness to the end; showing a series of rings and a black tip: ears slightly rufescent externally, but infuscated, passing to black at tip where there is a distinct small pencil tuft of black hairs; paws deep sooty black underneath, I lately saw, at Allahabad, an exact counterpart of this alleged wild race in a domestic Grimalkin; but, in general, the domestic Cats of this type, about Calcutta at least, are greyer, with the spots smaller and more numerous. The other type much resembles *F. Chaus* in colouring, but does not at all approximate to that animal in its proportions: it is much smaller than the Chaus, with proportionally shorter limbs, smaller ears, and much longer tail, which last distinctly tapers at the extremity, consequently, it exhibits no tendency to the *Lynx* form and character, so conspicuously manifest in the Chaus. The body is uniformly grizzled "cat-grey" more or less rusty or fulvescent, without a trace of spot or stripe, such as may generally be discerned faintly in the Chaus: but the bands on the limbs are much more distinct than in that animal, those of the tail equally

## FIBROUS PLANTS OF WESTERN INDIA.

head and cheeks (much confused albeit on the former). And a dark band across the chest: lower parts more or less whitish or tinged with fulvous, and marked with blackish or brown-black spots: ears dull, rufous behind, with a slight blackish tip and no pencil-tuft of hairs: the paws more or less sooty underneath. Domestic Cats of this type abound in Bengal, if not generally over India: but such a coloration is utterly unknown among those of Europe: and the proper tabby markings (pale streaks on a black ground, peculiarly and symmetrically disposed), so very common in English Cats, are never seen in those of India! The tabby may be a modification (and a very remarkable one) of the markings of the wild *F. sylvestris* of Europe, a result of domestication but most assuredly the Chaus coloured cats of India would seem to indicate an aboriginally wild stock of that colour, no doubt inhabiting the country somewhere: but if a truly and aboriginally wild specimen were to turn up, it would merely be regarded as a stray member of the domestic race, and so an end to all enquiry.

The only guide to a probably correct result would be the fact, that such animal might inhabit a vast range of country, away from human haunts, without exhibiting the variation of colour everywhere observable in the domestic races; unless in neighbourhoods where it might interbreed with the latter which would pass for nothing: though to such neighbourhoods it would doubtless be attracted, just as the Chaus is! The question then remains—Do two such Feline types exist, or either of them, in an aboriginally wild state, in any part of India, as have just been described, and both of which are said to be found wild in the Punjab Salt Range? The difficulty of tracing the origin of many of our domestic animals is well known.—*Jour. As. Soc. of Beng., No. V. 1856, page 442-3.*

(749) FIBROUS PLANTS OF WESTERN INDIA being from Art. II. on the use of Fibrous Plants in Bombay Review.

On the Western side of India we are less richly provided with those gigantic grasses, which in the valleys of the Ganges and Brahmapootra form such important parts of household economy. Still in our forests or dangs and in some of the internal rivers of Guzerat there are supplies sufficiently

## FIBROUS PLANTS OF WESTERN INDIA.

try to turn them generally to account. That they can be partially worked up into a shape at once useful, light, and elegant, may be seen in those tent-houses constructed of reeds which form the dwellings of our Indian gipsies, gopalas and other wandering tribes. Some of these huts can with ease be carried on a small donkey, and the material is so closely woven as to resist the heaviest rain. Possibly, had our brave troops at Sebastopol possessed a few thousands of them they might have been saved much sickness and suffering between November and March. That the use of such fabrics is not extended even to our floors is a proof how backward certain small but very useful branches of art are with us in Bombay. Our most finished artisans in Bombay cannot turn out a decent tent screen or chick. They have not yet got beyond a few coarse strips of bamboos strung together. Yet in this small branch of art thousands of people might be employed but instead however we go on purchasing China matting to the detriment of our purses as well as of our poorer population. Why should not young Bombay make a beginning in this division of industry. It is true that in Sind the manufacture is more extended and the grass chairs of that province as well as the boat mats are models for lightness and comfort.—Page 253.

*Musa textilis.* We now turn to the Plantain Tribe or Musas, about which Doctor Royle is as usual full of information collected as well as original. We may however state that he errs in one point of great importance, viz., that the wild Plantain (*Musa textilis*) is not indigenous in India. It can be shewn on our Ghats from Cape Comorin Northward, and if hitherto it has not been turned to full account this may be ascribed partly to ignorance or apathy on the part of those whose mountains afford many other fibres; and partly to the fact, that in the northern slopes of the Ghats, the plant does not reach a height fitted to afford a fibre or more than two feet in length. Strength it has as is well known to the Ghat people who employ it occasionally for domestic purposes in rope-making as well as the stem for food. However it is a question whether in our more Northern Ghats in which the growth is common the stem be not too short to allow of its being worked into exportable fibre.—Page 254.

*Cocoanut.* In Malabar and Ceylon every available spot within the influence of the sea breeze is being devoted to the growth of the Cocoanut, and an intelligent traveller has lately informed us that along the Western coast of the Madras provinces the wavy downs near the sea borders which have erst been barren and produced only a stunted and worthless crop of grass are being every where levelled broken up and manured so as to form the beds of future plantations, the only impulse being a steady de-

## FIBROUS PLANTS OF WESTERN INDIA.

velopment of the resident Collector (Mr. Maltby) who gives a perpetual lease of such ground at the easy rate of one rupee per acre.

The value of the coir produce depends so greatly on the previous manipulation that it appears most desirable to have it exported from the principal seaward ports, under the inspection of Custom-house or other authorities as used to be done in former years. We have been given to understand that since the abolition of the practice of government inspection, the coir prepared by private hands bears a relative value from 70 to 90 per cent. inferior to that prepared under the eye of public functionaries. We believe that a proposal to re-establish the old system was negatived as at variance with the principles of political economy.—Page 255.

*Linseed.* We conceive that Dr. Royle is in error when he states that this crop is never sown thickly or in continuous fields. We have seen it thus grown in many situations and such we believe to be the general mode of its cultivation in the Linseed-producing provinces. In our poorer Western districts it is often sown as an edging crop to wheat and other grain because it is not eaten by cattle in the green state. The reason given for its being sown in both long and cross drills is that the plant being weakly requires much sowing to guard it against the action of the weather and a very good and sufficient reason it is.

*Bast.* Of these our substitutes for Bast we need only remark that while they rank among the easiest grown and most extensively distributed of all our forest trees, they usually suffer more from the axe of the woodsman and the flames lighted by the cultivator of the jungle, &c., than almost any other class of trees. Consequently in places where they were once abundant, trees are now rare so that we can hardly expect to obtain their fibres in sufficient quantities for exportation.

It is true that in forests under the Western Ghats far to the southward they are still to be found in considerable numbers, but in such places the population is too scattered and migratory to take up the manufacture steadily and on an extensive scale. Provided they get a supply for making nets to catch the elk or fetters for the tame elephant they generally seek no more. For the latter purpose they frequently use the bark of some of the Sterculias.—Page 259.

*Crotalaria.* These remarks may serve as an introduction to the important subject of Sunna or Crotalaria fibre, as the Hibiscus Cannabinus or Ambaree, need be but lightly noticed, for it is not likely to be ever largely exported, and its uses will continue to be chiefly confined to the agricultural population of its native spots. With respect to the Sunna fibre we may observe that it is daily becoming an article of increased export and of growing importance particularly in

## FIBROUS PLANTS OF WESTERN INDIA.

the great agricultural districts to the east of the Godavery, and hundreds if not thousands of carts may now be seen conveying it in the dry season from the Eastern parts of Barsi, Pangam and Sholapore towards Bombay. Nor is it here only that such activity is observable, it is just as great in Malabar, Canara, Darwar, Mysore, and all the great grain countries to the south. In Khandeish, the quantity grown has more than doubled during the last ten years. In the Conkuns, owing to local causes which we shall notice hereafter, its culture has remained stationary if indeed it has not decreased. Throughout the greater breadth of Guzerat the land is too valuable to admit of its being subjected to the rotation of a crop held in so little esteem as this, both Brahmans and the higher classes of cultivators consider it beneath them to cultivate sunn, indeed there is a common belief, that a cow in calf, if tied with a rope of Sunna will miscarry. In Guzerat, however, it is often sown for a green manure being ploughed in to the land just after the flower has appeared. Also in the collectorate of Broach, it is somewhat extensively cultivated on those broken lands and edges of ravines which decline from the level of the Khannum or black soil to the Myhee river. In cleared patches of the different forests which skirt and lie at the foot of the Ghats, it is said to be regularly cultivated as a rotation crop. In Khandeish the Brinjaries, (the great grain carriers of the country) grow it in spaces which they clear near their temporary camps in the rainy seasons and in the hilly parts of Mysore, large camps of the same wandering tribe may be seen with their small huts or lightly stretcheed tents of cloth pitched near the slope of a great river, while their cattle are browsing among the neighbouring heights, and whole families are busied either in attending to the cultivation of Sunna or in working up such material as they have collected from the crop into twine and cloth. For the former purpose the hemp has to be prepared by a tedious and laborious process of beating on a flat stone or wooden block, successive blows being dealt by the men, each of whom is armed with a heavy club. By this means the woody fibre is pretty effectually got rid of and the article is then handed over to the women, boys and girls of the company to be by them spun into twine on the rude spindle or pirn which they always carry with them. It is no uncommon thing to see one of their stout wiry and bronzed vizages—for such they always appear in the line of march, stalking along with a child on her back, her eye fixed on the movements of the cattle and both her hands employed in mechanically twisting the fibre of the twine on this spindle.

In our districts below the Ghats the cultivation of some is limited to that grown by the wilder mountain tribes, and the Mussulman and Hindoo fishermen for their nets. Further cultivation seems to be restrained partly by fiscal

## FIBROUS PLANTS OF WESTERN INDIA.

measures and still more by the want of fresh water for steeping the fibre.—Page 260.

We have alluded to the practice of sowing the Sunna plant for the purpose of a green manure. This is but one of many instances which prove that the natives appreciate more fully than they have been supposed to do the effect of manures decomposing in the soil and we have also authentic documents to show that very many years ago the use of liquid manure specially carted for the purpose of distribution was common in some parts of the country.—Page 262.

*Combretaceæ.* The withes of two species of the Combretaceæ are extensively employed in the place of iron stretchers for the mouths of the leathern sacks used in drawing water from wells.—Page 263.

*Cannabis sativa.* We may mention that the Mussulman population are just as great consumers of the hemp product as the Hindus. In Sind the extent to which it is used by all classes is frightful.—Page 264.

*Paper.* Dr. Royle concludes by devoting a short chapter to “materials for paper making,” noticing also some of the places at which paper is manufactured. To this we need only add, that in Western India paper is made at numerous places as Ahmedabad, Surat, Dharwar, Kolapore, and Aurungabad, that in every manufactory which we have seen the workmen were all Mussulmans, that the paper made at Aurungabad bears the palm as to fineness and gloss, hence the demand for it to engross sunnuds deeds and other such documents. For royal use, as may be seen in the private account books of the late Peshwa Bajee Rao, grains of gold leaf are mixed with the pulp and thus becomes spread over the surface of the paper. We believe that in all cases the pulp is formed from old grain bags originally made from the *Crotalaria* Hemp or Sunne. Although the import to Bombay from Bengal of jute gunny bags for packing is considerable, we have never known them applied to the manufacture of paper.—*Bombay Quar. Review*, page 265 of No. IV. of 1855.

*Fibrous plants of Travancore.*—*Ailantus malabaricus*, *Paroomarum*, *Malayalum*, Inner bark. Not much used.

*Agave americana.*

*Acacia leucophloea*, Oody nar. This tree is common near Cape Comorin. The fibres from the bark are used by the fishermen in making nets. A coarse kind of cordage is also made from it.

*Aloe indica*, or *vulgaris*, Kuttally nar.

*Asclepias gigantea*, Ericoo nar, Common.

*Bauhinea tomentosa*, Vellay Aateenar.

*Callicarpa lanata*, Thondy nar. Inner Bark. Not much used.

## FIGHTING STRENGTH OF THE FRONTIER CLANS OF INDIA.

*Crotalaria juncea*, Canambo or Wuckoo. Cultivated extensively in the Southern districts. It is not exported. Fishing nets are made from them; the best kinds are grown in the Northern districts.

*Cordia obliqua*, Pothooveroosen nar. Moderate strength.

*Erythrina indica*, Moorookoo nar. Moderate strength.

*Ficus indica*, Aallen nar. Not much used.

„ *mysorensis*, Kul-aallun nar. Not much used.

*Grewia rotundifolia*, Oonoo. Moderate strength.

*Isora corylifolia*, Kywen nar. This is the most valuable fibre in Travancore. The plant grows abundantly at the base of the hills. It is from the stem of this shrub that the natives produce fire.

*Mimosa Intsia*, Eenjy nar.

*Sida populifolia*, used for Cordage. &c.

*Strychnos potatorum*, Kathaven nar.

*Smilax ovalifolia*, Krinkoddy nar. Used for tying bundles. &c.

*Sansevieria zeylanica*, Marel nar. Excellent fibre when well prepared.

*Terminalia alata*, Mooroothen nar. Bark, very strong and lasts many years: used for dragging timber, cordage. &c. Common in the forests.

*Terminalia bellerica*, Umburathee nar.

*Pandanus odoratissimus*, Thalay nar. This plant grows abundantly in Travancore along the backwaters and canals, the fibres are extensively used, being good and strong.—*M E J. R.*

(750) **FICUS**. Of this genus are the Banyan *Ficus indica* or Ala nar, Peepul, *Ficus religiosa* or Arasa nar, *Ficus racemosa*, Atti nar, *Ficus oppositifolia*, Bodda nar, *Ficus* (?) Culletthy nar, and the *Ficus tomentosa*.

(751) **FICUS BENGALENSIS**. (*Nyong bondee*, Bur.) is the genuine banyan.

(752) **FICUS RELIGIOSA**. (*Pipal*, Bur.) often called *Banyan*, is the sacred tree of the Burmans. Under it Gaudama is said to become a Boodh. It is common in every part of their country. The branches do not descend and take root like the genuine banyan. It is a very noble tree, and bears a fruit the size of a grape, of which birds are fond, but which is not eaten by man. One of these grows over the brick baptistry, in the Mission compound at Maulmain, extending its branches also over the street. On its young and flourishing branches the Burmans sometimes hang lighted lamps as a deed of merit.—*Malcolm's Travels in South Eastern Asia*, V. I. p. 186.)

(753) **FIGHTING STRENGTH OF THE FRONTIER CLANS OF INDIA**. Writers have from time to time described the policy adopted by the British Government towards these clans, and its success appears at last to be acknowledged. We question, however, whether the magnitude of

that success is even yet thoroughly appreciated. The immense length of the territory to be watched, the barbarous names of the clans who from time to time descend upon the plains, and the apparent want of connection in our own movements perplex and weary the most attentive. The public thinks of “the frontier” much as if it were an outlying station in some danger from the tribes around. We have seen some statistics which will, we think, tend to diminish this delusion. They shew that the clans whom we have compelled to respect our territory, can turn out a force greater than the whole Army of Bengal. That they require even now an army of observation greater than the force which defended the Peninsula. That the Government has in fact placed the chain upon tribes as wild and almost as numerous as those who have for centuries maintained the independence of Arabia.

The numbers stand as follows. Beyond British territory we have,

### Fighting men.

Tribes on Huzara Frontier and near the

Indus—North of Peshawur, ...	8,000
Swat and its dependencies, ...	20,000
Momunds, ...	12,000
Afreedies, ...	20,000
Oruckzyes and other Tribes in Kohat Frontier, ...	30,000
Wuzceries, ...	20,000
Sheoranees and others in Dehra Ismael Khan District, ...	5,000
Belooch Tribes on Dehra Ghazee Khan border, ...	20,000

Total 135,000

Besides the above there are other warlike Tribes within British Territory with the following numbers of

### Fighting men.

Turnoulees (including Jehandad), ...	8,000
Other Tribes of Huzara ...	10,000
Eusufzye, ...	25,000
Khuttucks, ...	12,000
Bungushes, ...	15,000
Derajat Tribes, ...	10,000

Total 60,000

These men are all, be it remembered, trained from boyhood to the use of arms. All can use the tulwar, the long assassin's knife, and the long and heavy matchlock. All are fanatic Mussalmans, clinging like mountaineers everywhere to the worst dogma of their faith, that the slaughter of an infidel is the readiest road to heaven. All, too, are accustomed to consider plunder the easiest source of income, and robbery the only profession worthy of an honourable man. Add to these facts, that they have for ages regarded the people of the plains as serfs born to till for the benefit

## FISHES OF THE CELEBES.

of the mountain and that these serfs can be attacked through all the passes of ranges which extend for eight hundred miles, and the task of the Government may be partially comprehended. The figures, too, may serve to explain the necessity for the great force which is now concentrated in the frontier stations:—

	Regular.	Irregular.	Total.
Huzara, ... ..	1,884	1,884	
Peshawur, ... ..	10,754	2,538	13,292
Kohat, ... ..	67	3,559	3,626
Dehra Ismael Khan,	3,204	3,204	
Dehra Ghazee Khan,	1,615	1,615	
<b>Total</b>	<b>10,821</b>	<b>12,800</b>	<b>23,621</b>

It is fortunate, if not for the existence, at least for the stability of our rule that these tribes are incapable of combination. They live in incessant bloodshedding feuds. Life for life is the universal law of the mountain, and the feud once commenced can end only with the destruction of one clan or the other. They have but one common bond, the hatred of the infidel, which from time to time urges individuals to acts of homicidal frenzy. That bond, however, is sufficiently powerful to give rise to some apprehension. A union among these tribes is considered in the Punjab an impossibility. Feuds as deadly were pacified in Arabia, when tribes equally wild and not more fanatic united for the conquest of the Oriental world.—*Friend of India*, 3 April, 1856.

(754) FISHES OF THE CELEBES. A Contribution to the knowledge of the Ichthyological Fauna of Celebes.—By Dr. BLEEKER, Director and Secretary of the Batavian Society of Arts and Science, &c.

The Ichthyological Fauna of the great island of Celebes has, up to this day, never been treated of by itself. The few notices regarding it are scattered through some Ichthyographic and Ethnographic works, principally in the treatises entitled—

“Schetsen uit de oostelyke streken des Indischen Archipels, door Jelluller.”

“Overzicht der uit de Sunda en Moluksche Zeen bekende visschen van de geslachten Amphiprion, Premnas, Pomacentrus, Glyphisodon, Dascyllus en Heliases, door H. Schlegel and J. Muller.

Both are inserted in the “Verhandelingen over de natuurlyke geschiedenis der Nederlandsche Overzeesche bezittingen” as well as in the “Histoire Naturelle des Poissons” by Cuvier, and Valenciennes.

In the various works I find mentioned 91 species of fishes belonging to the fauna of Celebes. Dr. Muller alludes to the existence of some genera at this place, without giving a description of their different species.

## FISHES OF THE CELEBES.

By comparing all the known genera and species I obtained the following summary:—

Families.	Genera.	Species.	Families.	Genera.	Species.
Percoides, ... ..	13	21	Scopelini, ... ..	1	1
Scleroparei, ... ..	3	4	Clupesoces, ... ..	2	2
Scenoides, ... ..	4	5	Clupeoides, ... ..	4	2
Sparoides, ... ..	3	3	Pleuronectoidei, ... ..	2	0
Chaetodontoidei, ... ..	10	5	Lophobranchii, ... ..	1	0
Osphronemoides, ... ..	2	2	Balistini, ... ..	3	3
Scomberoides, ... ..	7	11	Gymnodonta, ... ..	1	2
Theutides, ... ..	1	1	Seyllia, ... ..	1	1
Mugiloides, ... ..	2	1	Carchariae, ... ..	2	2
Gobioides, ... ..	5	5	Squatimorajae, ... ..	1	1
Labroides Ctenoides, ... ..	4	10	Torpedines, ... ..	1	1
Labroides Cycloides, ... ..	6	2	Trygones, ... ..	1	1
Siluroides, ... ..	3	1	Myliobatides, ... ..	1	1
Scomberesoces, ... ..	3	5			
	66	176		87	93

The genera and species here mentioned are detailed in the following table. The habitats of many of these are known; of others nothing is yet ascertained, but that they are found on and along the coasts of Celebes:

Families.	Species.	Habitat.
Percoides.	Ambassis Dussumieri, C. V. ....	Celebes.
	Apogon novemfasciatus C. V. ....	Macassar.
	„ nigripinnis C. V. ....	„

The above review shows sufficiently the analogy of this fauna to that of Java. Yet there are numerous species among those enumerated, which were never observed by me on or near the coast of Java, and which are nowhere mentioned as being found on these coasts. The species not known in Java are the following, viz:—

<i>Apogon novem fasciatus</i> C. V.	<i>Eleotris velobrancha</i> ... C. V.
<i>Serranus merra</i> C. V.	<i>Amphiprion ephippium</i> Schn.
<i>Dicope bitaeniata</i> C. V.	" <i>percula</i> C. V.
<i>Mesoprion taeniops</i> C. V.	<i>Pomacentrus albifasciatus</i> M. Schl.
" <i>fuscescens</i> C. V.	" <i>nigricans</i> C. V.
<i>Dules maculatus</i> C. V.	<i>Cossyphus Schoenleinii</i> Agaz.
<i>Platycephalus pristiger</i> C. V.	<i>Novacula pentadactyla</i> C. V.
<i>Pterois zebra</i> C. V.	<i>Belone annulata</i> C. V.
<i>Dentex obtusus</i> S. Mull.	" <i>timucoides</i> S. Mull.
<i>Chorinemus mauritanus</i> C. V.	<i>Hemiramphus melanurus</i> C. V.
" <i>aculeatus</i> C. V.	" <i>erythrorhynchus</i> C. V.
<i>Caranx Forsteri</i> C. V.	<i>Alutera barbata</i> S. Mull.
<i>Coryphaena chrysurus</i> Lac.	<i>Tetraodon Honkenii</i> Bl.
<i>Amphacanthus vulpinus</i> Mschl.	" <i>argenteus</i> S. Mull.
<i>Certraeus plicatilis</i> C. V.	<i>Narcine Timlei</i> Henle.
<i>Gobius celebius</i> C. V.	<i>Aetobatis flagellum</i> M. H.
<i>Sicydium cynocephalum</i> C. V.	

Consequently, according to our present knowledge, we have 33 of the above enumerated 93 species, which are entirely strangers to Java, whilst the remaining 60 are found inhabiting the waters along the coast of Java.

Some weeks ago I received a small collection of fishes from Macassar, for which I am indebted to the kindness of my friend, the naturalist traveller Zollinger, who collected them for me during his stay at that place. Though this collection consists only of 21 species, yet it is remarkable for the following peculiarities, viz.

# FISHES OF THE CELEBES.

1st. 15 species are new to the Fauna of Celebes.

2nd. 4 species cannot be classified amongst the genera known hitherto, but render it necessary to form 4 new genera.

3rd. Besides these, 4 or at least 3 species, there are 8 others also new to science, so that one half of the collection consists of species altogether unknown.

4th. The remaining 4 species already known also belong to the fauna of Java.

The species of this collection belong to 9 families and 18 genera, viz.

Percoidei. <i>Therapon theraps</i> C. V.	Siluroidei <i>Plotosus lineatus</i> C. V.*
<i>Holocentrum leonoides</i> Blkr.	Scopelini <i>Saurus badi</i> C. V. *
<i>Sillago acuta</i> C. V. *	Clupeoidei <i>Clupea gibbosa</i> Blkr.
Sparoidei <i>Dipterygonotus leuco-grammicus</i> Blkr.	" <i>argyrotaeniata</i> Blkr.
<i>Apogonoides macassaricus</i> Blkr.	" <i>macassariensis</i> Blkr.
Chaetodontoidei <i>Drepane guttata</i> C. V.	Amblygaster <i>clupeoides</i> Blkr.
<i>Scatophagus argus</i> C. V.	Engraulis <i>Zollingeri</i> Blkr.
<i>Toxotes jaculator</i> C. V. *	Balistini <i>Balistes melanophlæum</i> Blkr.
Scomberoidei. <i>Caranx leptolepis</i> K. H.	<i>Pogonognathus barbatus</i> Blkr.
" <i>pseudopterygius</i> Blkr.	<i>Triacanthus biaculeatus</i> C. V.
Mugiloidei <i>Atherina argyrotaeniata</i> Blkr.	

The species marked thus\* are found in the tables at the head of this contribution. By the 15 species new to the Fauna of Celebes the number of all the species of its fishes is raised to 108, that of the genera to 91, viz. :—

Percoidei.....	13 Genera, 23 Species.
Sparoidei..	5
Chaetodontoidei...	7
Scomberoidei.....	13
Mugiloidei.....	2
Clupeoidei.....	7
Balistini.....	4

leaving the numbers of the remaining families as enumerated in the beginning of this treatise.

Overlooking the species marked\* we find only 4 among those new for Celebes also known in Java, viz: *Therapon theraps* C. V.; *Drepane guttata* C. V.; *Scatophagus argus* C. V.; and *Caranx leptolepis* K. v. H. Thus of the 108 species of fishes known in Celebes 64 are also found in Java.

Celebes most probably has much greater abundance of fishes than Java. Notwithstanding this we know comparatively but a small number of species. I am of opinion that 108 expresses not yet the eighth part of the number of all the species of fishes actually living in Celebes and in its coast waters. There is still to be found a rich treasure for science, not only in ascertain-

## FISHES OF THE CELEBES.

ing the geographic dispersion of the species already known, but also in discovering entirely unknown ones. This would appear to a certain degree from the comparative richness of the collection by M. Zellinger, of which nearly half of the number of species are new in Ichthyology.

A few words only regarding the new genera formed by me; I have named them *Dipterygonotus*, *Apogonoides*, *Amblygaster* and *Pogonognathus*.

The two former belong to the family of the Sparoidei of S. Muller (*Sparoide* and *Maendoles* Cuv. Val.)

The *Dipterygonotus* is distinguished by his snout prolonged into a horizontal tube, by two diverging fins without scales, toothless gill covers, a small flat thorn at the operculum, scaled joles and absence of jaw bone and erect teeth.

*Apogonoides* thus named by me from its resemblance in habitat to divers sorts of *Apogon*, has likewise two diverging dorsal fins and toothless gill covers, but no thorn at the operculum, the snout but little prolonged, small bristly jaw teeth and erect and canine teeth.

The 3rd of the genera formed by me belongs to the Clupeoidei, and has a great affinity to the genus *Clupea*, from which it is chiefly distinguished by a flat round smooth belly, a character which I tried to express by the word *Amblygaster*. *Amblygaster* has a long compressed body, a round unspiked belly, 5 rayed gills, the eyes partly closed by a membrane, a naked head, no teeth.

With regard to the novelty of the genus belonging to the Balistini, called *Pogonognathus*, I am not quite certain. Remote from every centre of science, confined altogether to my own library and not in possession of some Ichthyographic works, I cannot positively decide whether the *Aluteres cryptacautus* Cuv. (Renard II part p. I 2f. 284) or the *Anacanthus barbatus*, Gray, illustrated in the Ind. Zool. Vol. I. Tab. 84 f. 2, be identical or related to my *Pogonognathus barbatus*. The *Alutera barbata*, mentioned by S. Muller in his above mentioned treatise, is there only enumerated without being described, so that I am likewise uncertain with regard to that species, whether it is the same with that discovered by me. I am inclined however to identify both of them, since they were found at the same spot, and I know of no species of *Aluteres*, with one or more cirri in the underjaw. It must be reserved to zoologists, who can command a greater share of literary aid than I, on this unscientific spot of the earth, to remove the uncertainty on the point. *Pogonognathus* is nearly related to *Aluteres*, but is distinguished from the latter by a large membranous cirrus on the chap, and a single dorsal fin formed merely by a bony fibre. The characteristic marks of the *Pogonognathus* are a long compressed body covered with a short downy hair,

## FISHES OF THE CELEBES.

a thin bony fibre instead of a dorsal fin, a thick membranous feeler at the chin, the bones of the pelvis concealed under the skin;—the pelvis of the males projecting.

I shall now enter into a short description of the new species. I have added the diagnosis of a kind of *Caranx* which I consider to be the *Caranx leptolepis* K. v. H., also that of the East Indian Sailor [*Oostindisch vaarder*] mentioned by Valentyn, called by me *Balistes melanopleua*.

### *Speciarum Diagnoses.*

#### *Percoidei.*

(755) *Holocentrum leonoides*, Blkr.

Hol. linea fronto-dorsali convexiuscula, spinis opercularibus inequalibus, preoperculari longa bisulcata, operculi limbum posteriorem multo superante; dentibus suborbitalibus 2 majoribus; lateribus verticis striis 6-7 divergentibus; spinis dorsi crassis pinna caudali profunde biloba lobis rotundatis; colore corporis pinnarumque argentes rubro, fasciis et maculis nullis.

D. 11—I/14, P. I/12, VI/7, A. 3/10, C. 19 et lat brev.

Habit. Macassar Mare.

#### *Sparoidei.*

(756) *Dipterygonotus* Blkr.

Dentes maxillares, vomerini et palatini nulli. Ossa opercularia non dentata, operculo spina unica plana. Os in tubum horizontalem protactile. Pinnæ dorsales duæ distantes, non squamatae. Genæ squamatae. Membrana branchiostega radiis 7.

(757) *Dipterygonotus leucogrammicus*. Blkr.

Dipt. conore elongato compresso, altitudine  $5\frac{1}{2}$  in ejus longitudine, capite 5 in corporis longitudine, linea laterali recta; pinna dorsales spinosam inter et radiosam spinis humilibus liberis 4; squamis parvis ciliatis; pinna angulatis, caudali propende incisa; colore verticis et dorsi coeruleo, vittis longitudinalibus albis 3, laterum ventris que argenteo, pinnarum flavescens hyalino.

B 7. D. 10-4-1/9, P. 1/13, V. 1/5, A. 3/10, C. 17 et later. brev.

Hab. Macassar Mare.

Species habitu corporis *Cæsiotile* Cuv. Val. affinis.

(758) *Apogonoides* Blkr.

Dentes maxillares setacei, palatini et vomerini nulli Ossa opercularium non dentata, operculo spina nulla Os parum protractile. Pinnæ dorsi 2 distantes, non squamatae membrana branchiostega radiis 6.

(759) *Apogonoides macassariensis* Blkr.

Ap. corpore oblongo compresso altitudine  $4\frac{1}{2}$  circiter in ejus longitudine, capite 4 in corporis longitudine, pinna caudali biloba.

B. 6, D. 6—1/9. P. 11, V. 1/5, A. 2/11, C. 16.

Hab. Macassar Mare.

Species habitu *Apogon glaga* Blkr. affinis

## FISHES OF THE CELEBES.

*Specimina 7 minus bene conservata colores nec viscera monstrant.*

### *Scomberoidei.*

(760) *Caranx pseudopterygins* Blkr.

Car. pinnis dorsalibus 3 posteriore spuria; corpore elongato, altitudine 5 in ejus longitudine; capite 4 in longitudine corporis, line fronto dorsal fere recta; dentibus minimis; maxilla inferiore superiore longiore; prae-operculo rectangulo rotundato; membranae oculi adiposae parte posteriore lata; linea laterali parte posteriore tantum armata, scutis latis p. m. 30, dentatis, pinna pectorali 5 in longitudine corporis; colore corporis supra caerulescente infra argenteo, pinnarum omnium flavescente, maculis nigris nullis.

D. 1 procumbens 8— $1\frac{1}{32}$ —1, P. 2/20, V.  $1\frac{1}{5}$ , A. 2— $1\frac{1}{27}$ , C. 18 et lat. brev.

Hab. Macassar Mare.

Species *Caranx kiliche* C. V. et *Caranx kurra* C. V. affinis sed proportionibus numeroque radiorum distincta.

(761) *Caranx leptolepis* K. v. H. Cuv. Val. Hist. Pois./IX. P. 48.

Car. pinnis dorsalibus 2, corpore elongato humili, altitudine  $3\frac{1}{2}$  ad 4 in ejus longitudine; capite  $4\frac{1}{2}$  in longitudine corporis, linea fronto-dorsali leviter convexa, dentibus fere inconspicuis; praeoperculo rectangulo rotundato, linea laterali usque ad mediam pinnam dorsi radiorum flexuosa, in portico, ejus parte tantum scutata, scutis parvis vix dentatis; thorace squamato; pinna pectorali 4 in longitudine corporis; colore supra caerulescente infra argenteo, macula operculo humerali nigra, pinnarum omnium flavescente.

D. 1 procumbens 8- $1\frac{1}{26}$ , p. 2/17, V.  $1\frac{1}{5}$  A. 2- $1\frac{1}{22}$ , C. 17 et lat. brev.

Hab. Macassar Mare.

### *Mugiloidei.*

(762) *Atherina argyrotaeniata* Blkr.

Ath. corpore elongato cylindrico, altitudine  $6\frac{1}{2}$  in ejus longitudine, antice aequae crasso ac alto, capite  $4\frac{1}{2}$  in longitudine corporis, fronte convexa vertice plano; oculis  $2\frac{1}{2}$  in capitis longitudine; ore de livo, praeoperculi margine postico excise; nonnullis poris lacunosus ad latera capitis sub oculis et maxilla inferiore; squamis magnis; linea laterali paulum conspicua; marginibus pinnarum dorsalis secundae et analis superioribus excavatis; pinna dorsali secunda medius fere interpinuas ventrales et analem; pinna pectorali  $5\frac{1}{2}$  in longitudine corporis; colore corporis dorso viridescente, ventre ex roseo argenteo, lateribus vitta lata nitente argentia, supra limbo caeruleo; pinnis hyalinis; iride marginem superiorem versus macula nigra.

D. 6- $1\frac{1}{9}$  vel.  $1\frac{1}{10}$ , P.  $1\frac{1}{14}$ , V.  $1\frac{1}{5}$ , A.  $1\frac{1}{10}$ , C. 15 et lat. brev.

Hab. Macassar Mare.

Species *Atherina Forskaeli*, Rupp. affinis sed forma capitis, numero radiorum analium etc. distincta.

## FISHES OF THE CELEBES.

### *Clupeoidei.*

(763) *Clupea macassariensis* Blkr.

Clup. corpore elongato compresso, altitudine 7 in ejus longitudine, capite acuto  $4\frac{1}{2}$  in corporis longitudine; ore antico edentule; squamis magnis; linea laterali recta; ventre paulum carinato; pinna dorsali medio dorso posita; colore dorso caeruleo, lateribus et ventre argenteo, basi caudal striis 4 caeruleis longitudinalibus.

D. 2/9, P.  $1\frac{1}{11}$ , V.  $1\frac{1}{7}$ , A.  $1\frac{1}{8}$ , C. 18 et lat. brev.

Hab. Macassar Mare.

(764) *Clupea argyrotaeniata* Blkr.

Clup. corpore elongato compresso, altitudine 7 in ejus longitudine capite acuto 5 in corporis longitudine; ore antico edentulo; squamis magnis; linea laterali inconspicua; ventre paulum carinato; pinna dorsali medio corpore posita; colore ex flavescente hyalino, vitta laterali nitente argentea lata.

D.  $1\frac{1}{9}$  P.  $1\frac{1}{15}$  v.  $1\frac{1}{7}$ , A.  $1\frac{1}{12}$ , vel.  $1\frac{1}{13}$ , C. 18 et later. brev.

Hab. Macassar Mare.

(765) *Clupea gibbosa* Blkr.

Clup. corpore elongato compresso  $4\frac{1}{2}$  in ejus longitudine, dorso medio in gibbam elevato; capite 5 in longitudine corporis; ore antico edentulo, ventre valde carinato serrato; pinnis, dorsali postice an. anteriore corporis parte sita, subquadrata radio penultimo paulum longiore; ventralibus analique parvis, squamis mediocribus striatis; linea laterali conspicua; colore corporis dorso caeruleo, lateribus ventrequae flavescente argenteo, pinnis flavescente.

D. 2/15 P.  $1\frac{1}{15}$ , v.  $1\frac{1}{7}$ , A.  $1\frac{1}{20}$ , C. 19.

Hab. Macassar Mare.

(766) *Amblygaster* Blkr.

Ossa intermaxillaria parva; maxillaria os maxima parte constituentia, corpus elongatum compressum, ventre obtuso rotundato non serrato. Dentes nulli. Caput supra nudum oculi membrana semilecti. Genae venosae.

Membrana branchiostegaradus 5.

(767) *Amblygaster Clupeoides* Blkr.

Ambly. corpore elongato paulum compresso, altitudine 5 in ejus longitudine; capite 5 fere in corporis longitudine, ore antico, aculo  $3\frac{1}{2}$  in capitis longitudine; squamis magnis; pinnis acutis, dorsali triangulari, ventrali opposita, altitudine  $8\frac{1}{2}$  in corporis longitudine; ventralibus brevibus, squamis elongatis ad earum bases; anali humili,—colore corporis dorso caeruleo, lateribus ventrequae flavescente argenteo, rostro nigro; pinnis flavescente, pectoralibus rabus anterioribus postice fuscis.

B 5, D.  $3\frac{1}{15}$ , p.  $1\frac{1}{16}$ , v.  $1\frac{1}{7}$ , A.  $1\frac{1}{16}$ , vel.  $1\frac{1}{17}$ , C. 17 et later. brev.

Hab. Macassar Mare.

(768) *Engraulis Zollingeri* Blkr.

Engr. corpore elongato compresso, altitudine  $6\frac{1}{2}$  in ejus longitudine, capite  $4\frac{1}{2}$  in longitudine corporis, rostro prominente; rictu amplissimo;

## FISHES OF SUMBAWA.

ossibus maxillaribus servatis; ventrie inter pinnis pectorales, et ventrales cultrato; linea laterali nulla; squamis deciduis: supra pinnae pectorales squame magna acuminata; pinnis, dorsali pinnae ventrales inter et analem posita, caudali utroque latere lobis 2 membranaceis; colore corporis viride hyalino, vitta longitudinali lata argentea, pinnarum flavese cente.

D. 2/11, P. 1/12, V. 7, A. 17, C. 19.

Hab. Macassar Mare.

Species *Eugraulis heteroloba* Rupp. affinis, sed positione pinnae dorsalis numeroque radiorum distincta.

*Balistini.*

(769) *Balistes melanopleura*. Blkr.

Bal. corpore subparallelo grammico compresso, basi caudae seriebus tribus aculeorum armata, serie superiore aculeis 2 vel 3, inferioribus aculeis 10-12; pinnis, caudalit runcata, pectoralibus, dorsali analique rotundatis; linea laterali flexuosa; colore corporis supra profunde viridi, infra flavo, vittis 3 pectorali frontalibus caeruleis, macula nigrescente magna supra anum; colore pinnarum rosaceo flavescente, dorsalis analisque basi violaceo, vittis 2 caeruleis longitudinalibus.

D. 3-3/23, P. 1/12, A. 2/21, C. 12.

Syn. Oostindischyaarder. Valentyn. *Ind. Amb.* III. p. 400 fig. 173.

Hab. Macassar Mare.

(770) *Pogonognathus* Blkr.

Corpus elongatum valde compressum villosiusculum pinnae dorsalis primae loco filum osseum tenue unicum ossa pelvis sub cute occulta Maxilla inferior cirro carnosio unico magno. Dentes in singulis maxillis 4 acuti Mas pelvi producta.

(771) *Pogonognathus barbatus* Blkr.

Pog. corpore elongato, maxime compresso, altitudine, 12 in ejus longitudine, rostro maxime elongato; cirro inframaxillari dimidiam rostri longitudinem aequante; linea laterali flexuosa; pinnis, caudali excepta, radiis simplicibus dorsali anali humiliore, caudali longa acuta  $2\frac{1}{2}$  in corporis totius longitudine; colore capite, corpore rinnisque pectoralibus fusco, dorsali analique rufo, caudali fusco nigro maculato.

D. 1 filiformis—49, P. 10, A. 57, C. 12.

Syn. *Aluthera barbata*, S. Mull. 1. cit.

*A Contribution to the knowledge of the Ichthyological Fauna of Sumbawa.*

BY DR. BLEEKER.

Chir. Maj. Besturend Liden Secretaris v. h. Bat. Gen. v. k. en. W., Lid v. h. Amsterd. Genees en Heelk. Gen. v. d. Maatsh. v. Nederl. Letterk. te Leiden, v. h. Naturk. Gen. te Groningen, &c. &c.

## FISHES OF SUMBAWA.

The meritorious naturalist traveller H. Zollinger, had the goodness, during his residence at Bima on the island of Sumbawa, to collect for me a great many kinds of fishes. To the collection thus brought together by that learned person, this account is indebted for its origin.

Sumbawa was until this time totally unknown in an ichthyological point of view. Science is thus under new obligations to my friend Zollinger. The natural history of Netherland's India expected from him yet greater advances, but peculiar circumstances caused his return to Europe: the sense of his merits and my esteem and friendship for him, induce me to dedicate to him one of the yet undescribed species of fishes which he collected.

The fishes enumerated below were all taken in the sea at Bima. They naturally form but a small portion of the Ichthyological Fauna of Sumbawa. As a first contribution to the knowledge of this Fauna what follows will not be without value.

The species of the collection are 47 in number and belong to 35 genera and 19 families. They are as follows:—

Percoidei.....	* <i>Lates nobilis</i> C. V.
	* <i>Therapon servus</i> , C. V.
	<i>Ambassis nalu</i> C. V.
	<i>Apogonmul titaenia-</i>
	<i>tus</i> Ehr. C. V.
	„ <i>melas</i> Blkr.
	* „ <i>thermalis</i> C. V.
	* <i>Serranus crapae</i> C. V.
	* „ <i>pardalis</i> Blkr.
	<i>Mesoprion erythrop-</i>
	<i>terus</i> C. V.
	<i>Holocentrum sam-</i>
	<i>mara</i> C. V.
	* <i>Sillago acuta</i> C. V.
Scleroparei... ..	* <i>Pterois volitans</i> C. V.
	<i>Apistus Zollingeri</i>
	Blkr.
Sciaenoidei... ..	* <i>Pristipoma kaakan</i>
	C. V.
	* <i>Scolopsides lycogenis</i>
	C. V.
	<i>Heterognathodon bifa-</i>
	<i>sciatus</i> Blkr.
Sparoidei... ..	* <i>Chrysophrys cala-</i>
	<i>mara</i> C. V.
	* <i>Caesio erythrogaster</i>
	C. V.
Chaetodontoidei ... ..	<i>Chaetodon vagabun-</i>
	<i>dus</i> C. V.

	<i>Aleuterus lævis</i> Cuv.
Ostraciones,.....	<i>Ostracion cubicus</i> Block Cuv.
	<i>Ostracion valentini</i> Blkr.

Of the 47 species, the 21 marked with \* belong to the Fauna of Java, being thus about one half; 10 are new to science; the rest doubtful.

One species I have considered it necessary to place in a new genus, which I had previously established in 1844, but of which I have not yet published the characters. It is a genus of *Sciænoïedes*, which, related to the *Scolopsides*, is chiefly distinguished from them by the presence of 4 tusks in the upper and two in the under jaw, as well as by the non-thorned or thorn formed extremities of the os suborbibale. In my Contributions to the Medical Topography of Batavia I have named the first species of the genus discovered by me, *Heterodon zonatus*, which name I afterwards changed into *Heterognathodon xanthopleura*, as more descriptive of the genus and species. *Heterognathodon bifasciatus* of Bima is the second species belonging to this new genus,

## FISHES OF SUMBAWA.

but I believe it is the same species as *Scolopside caninus* Cuv. Val. which is given in the celebrated *Historie Naturelle des Poissons* at the end of the list of the species of *Scolopsides*.

Of some of the species already known to science, I have drawn up new diagnoses, even as I have done of some doubtful species. I must still lament that, from my unavoidable separation from the scientific world, I am not in a condition to lithograph the new species. I must await my return to Europe to publish my already partly completed *Fauna Archipelagi Indici Ichthyologica*. The efforts made by me with the government of Netherland's India for its publication have not only not been attended with the desired result, but, followed by a transference from Batavia to Samarang and Surabayá, have placed me even beyond the possibility of applying to the service of ichthyological science my cabinet, collected by the labours of many years and at great cost. Batavia, but a short time past the centre of science in Netherland's India, shall speedily be so no more. The scientific periodicals, the *Tijdschrift voor Neerlandisch Indie*, the *Natuur en Geneeskundig Archief voor Netherlandisch Indie*, the *Indisch Magazyn*, on whose existence these possessions might pride themselves, have all fallen to the ground. The year 1848 will be noted in the history of the Netherland's India as the last year of the decennium of its scientific activity. May the time come when science shall be again protected and supported here against the unfavourable influences which, in the midst of her bloom, have by little and little undermined and menaced her with total destruction.

I have allowed myself the preceding digression in order to shew why my ichthyological publications are not yet more numerous, and why they are not accompanied by plates of the species discovered by me.

I shall proceed to the diagnostical description of the doubtful, less known, and new species.

### *Percoidei.*

(772) *Apogon melas* Blkr.

Ap. corpore oblongo compresso, dorso elevato, altitudine corporis  $3\frac{1}{2}$  in ejus longitudine; capite æque longo ac corpore alto; linea rostro-dorsali rectiuscula; pinnis dorsali 2a rotundata, caudali margine posteriore concava; colore capite corpore pinnisque omnibus nigro.

D. 8.— $1\frac{1}{8}$  p  $2\frac{1}{2}$  v.  $1\frac{1}{5}$  A.  $2\frac{2}{9}$  C. 17.

(793) FISH OF NEPAUL. The fish in the Nepaul rivers are abundant. The principal kind which inhabits the Raptée, is the sehr, a fish much resembling the roach and greatly esteemed, and the gaoleer. The manner of fishing may be described in a very few words. The channel of the river is intersected by seven or eight casting nets, united together by being hooked at their extremities to poles, or sticks erected in the water for that purpose. To each net there is a man or boy, who has a second net fixed to his waist and hanging behind him, in which he deposits the fish he catches. This he does by diving. The fishermen dive head foremost, though in water not deeper than their middle, throwing up their feet nearly quite erect, and seizing the fish either with their teeth or their hands. After remaining some time at a particular spot, all the nets are dragged together further down the stream, when the fishermen renew their operations. These being over, they draw the casting nets separately; some of which, as well as those round their waists, are often quite full. In the river Tadi, which, augmented by the waters of the Sindoor and Bailhot rivulets, winds round the south point of the Chardi-baisi hill, there are eels of a very large size, and of excellent flavour. The usla, a fish not unlike the British salmon in taste, is also found in the Tadi, and the phaketa abounds in the stream. The phaketa is a small fish, remarkable both for the swiftness with which it glides through the water, and the singular construction of its superior fins, which resemble a fan both in form and in the manner in which they open and close.—*Smith's Nepaul.*

(794) FLACOURTIA CATAPHRACTA.

Puchuala | Panayala.

The fruit is edible. The small leaves and young shoots resemble rhubarb in flavour, and are used as gentle astringents in doses of three scruples. An infusion of the bark in cold water is useful in hoarseness.

## FLOWERS.

(795) **FLACOURTIACEÆ.** *Roumea*, *Poit.* *Roumea Habecarpa*, *Gardn.* A dioecious tree, 16-20 feet high. Rare in the jungles of the Central Province, as at Cundasalle: flowers in June. The only hitherto described species of *Roumea* is a native of St. Domingo, in the West Indies, for the *R. inermis* of De Candolle from Bengal seems to belong to a very different family. The present species is called *Katambilla* by the Cingalese, and the fruit, which is very acid, is used by them in their curries.—*Gardner, Calcutta Journal of Natural History, Vol. VII, pp. 449-50.*

### (796) FLOWERS.

#### USE OF FLOWERS.

God might have made the earth bring forth  
Enough for great and small,  
The oak-tree and the cedar-tree,  
Without a flower at all.

He might have made enough, enough  
For every want of ours;

For luxury, medicine, and toil,  
And yet have made no flowers.

The ore within the mountain-mine  
Requireth none to grow,  
Nor doth it need the lotus flower  
To make the river flow.

The clouds might give abundant rain,  
The nightly dews might fall,  
And the herb that keepeth life in man  
Might yet have drunk them all.

Then wherefore, wherefore were they made

All dyed with rainbow light;  
All fashioned with supremest grace,  
Up-springing day and night;  
Springing in valleys green and low,  
And on the mountains high,  
And in the silent wilderness,

Where no man passes by?

Our outward life required them not.

Then wherefore had they birth?

To minister delight to man

To beautify the earth!

To comfort man, to whisper hope,

Whenever his faith is dim;

For whoso careth for the flowers,

Will much more care for Him:

*Mary Howit.*

#### THE LANGUAGE OF FLOWERS.

In eastern lands they talk in flowers,  
And they tell in a garland their loves and  
cares;

Each blossom that blooms in their garden  
bowers,

On its leaves a mystic language bears.

The rose is a sign of joy and love,

Young blushing love in its earliest dawn;

And the mildness that suits the gentle dove,

From the myrtle's snowy flower is drawn.

Innocence shines in the lily's bell,

Pure as the heart in its native heaven;

Fame's bright star and Glory's swell

By the glossy leaf of the bay are given.

The silent, soft, and humble heart

In the violet's hidden sweetness breathes;

And the tender soul that cannot part,

## FOREST TREES OF WESTERN INDIA.

A twine of evergreen fondly wreathes,  
The cypress that daily shades the grave,  
Is sorrow that mourns her bitter lot,  
And faith that a thousand ills can brave  
Speaks in thy blue leaves forget-me-not.  
Then gather a wreath from the garden bowers,  
And tell the wish of thy heart in flowers.

*Percival.*

(797) **FOONG-HANG, OR CHINESE PHENIX**, a head ornament worn by Chinese ladies composed of gold and jewels, the wings lowering, and the beak of the bird hanging over the forehead on an elastic spring.

(798) **FOOTBALL.** This game is played by Malays in the following manner—the players stand in a circle, larger or smaller according to the number engaged, a ball made of split rattans, hollow and about 6 inches in diameter, is thrown up by one, the person to whom it approaches receives it on the instep of his foot and throws it into the air towards his nearest playmate who in like manner sends it on to the next, and so on: with expert players it is thus sent round from one to another an extraordinary number of times without falling—sometimes one player will himself, particularly when there are many on-lookers, keep the ball in constant motion, receiving it in the fall, now on his foot, now on his knee, elbow, head, shoulder, &c.—*Jour. Ind. Arch. Vol. V. No. 11.* The ball is a perfect sphere, and is so light it may be thrown almost with full force against any fragile object, without injuring the same. The introduction of this plaything into England would be a great matter, in households.

(799) **FOREST TREES OF WESTERN INDIA**, furnishing timbers, by Surgeon Alexander Gibson, F. L. S., 1857.

#### A

1. *Acacia arabica*, *Babool*.—Most common in the interior; less so on the coast, and hardly known in the southern jungles. As every one is acquainted with its uses for wheels, charcoal, &c. these need not be enlarged on here. There are two if not three varieties or species,—*Babool*, *Ram kanta*, and *Free babool*. The first is the most common species; the second less so, and distinguished from the first by its straight stem, and general appearance, resembling that of a gigantic broom. The wood is quite equal to that of the common *Babool*. The third species is distinguishable from the first by its more horizontal mode of branching; the smaller branches long, and stretched out, the side branchicles from them going off at right angles nearly. The bark, also is much more reticulated, broken, and corky than that of the other. The wood is very inferior, as regards its use for agricultural implements, house material, &c. The distinction between the

## FOREST TREES OF WESTERN INDIA.

two should always be kept in view as practically important. The pod of this third species, also, is much broader-margined, and very partially moniliform, and can be at once distinguished from that of the first two species, which is so contracted between each seed as to be nearly severed. The pods and tender branches of all the three species form an important article of food for sheep, goats, and cattle, from February to the beginning of the rains. The flesh of lambs fed on the pods has a flavour equal to that of the best Europe lamb.

2. *Acacia amara*, *Lullye*.—A tree common in the more inland jungles, and dry waste ravines; less so on the coasts. Wood is always very crooked; otherwise it is strong, and might be applicable to domestic purposes. The flower is very beautiful.

3. *Acacia catechu*, *Kheir*.—Is one of the most common trees in the coast and Ghaut jungles. Wood is of great strength and durability. Resists insects; therefore is used for posts and uprights of houses. The extract "catechu" is made from the heart-wood, and is the source of a small revenue in the Konkun. The tax is so much per "hearth," containing about 24 pots.

4. *Acacia Farnesiana*, *Free babool*, *N. B.*—This latter name is also applied to a variety of *Acacia arabica*.—A scrubby shrub, found in waste places, garden hedges, &c. It is not applicable to any other purpose than tent-pegs and firewood.

5. *Acacia leucophlœa*, *Hewur* (?)—I think this species embraces also our *Mimosa tomentosa*,—at least I have never found another to fit the former name. Wood is good, but never of a size for anything beyond posts to small houses.

6. *Acacia odoratissima*, *Sirrus*.—There appears no difference between *Acacia sirrus* and the present species. The white wood, which is always three-fourths of the whole, could probably, by being creosoted, form a useful railway timber. Tree is common both in the coast and interior jungles; often reaches a good size.

7. *Acacia odoratissima*, *Ran sirrus*.—I do not think there is any foundation for a distinction between this tree and the *Acacia serissa*. It is common in our forests, both coast and inland. The heart-wood is strong and excellent, but does not, I think, bear moisture. (Vide above.)

8. *Acacia speciosa*, *Sirrus*.—Vide remark in No. 7. Vide also *Acacia odoratissima*, No. 6.

9. *Acacia Sundra*, *Lal kheir*.—Is common in the inland jungles with us, but is there always scrubby, small, and crooked. It is also found rather plentifully in the forests under the Ghauts, but I have not there seen it of any size capable of affording planks.

10. *Ægle marmelos*, *Bel*.—Tree common in waste places, inland forests, and old gardens. Wood compact and hard, but is not used, more

perhaps from religious feeling than anything else. The beautiful ready-made varnish which surrounds the seeds will one day be turned to use in the arts. The fruit is strongly medicinal.

11. *Ailanthus excelsa*, *Warook*.—This tree is common, chiefly about old buildings, and in raviny ground of the Deccan and Guzerat. It is seldom found as a tree in the forest. I cannot confirm the accounts given by Dr. Wight of its good qualities, neither can I learn that it is ever used in cabinet-work in Bombay; but I give these opinions with diffidence, and in the view of inviting further trials or more information.

12. *Alangium decapetalum*, *Ankool*.—Tree common both in the open country and in some of the jungles, towards the coast, but it is less of a jungle tree than one found in hedges and village lanes. I have never seen one that would give a 10-inch plank. Root has a reputation in snake-bites.

13. *Alstonia scholaris*, *Satreen*.—Grows to be a very large tree in the South Konkun. I have not seen it north of Magotna. It affords excellent boards or thin planks for common purposes, as for pats for children at schools. Hence the name. The bark is valuable in medicine. This tree is not found inland, but appears to grow freely enough in the Botanical Gardens.

14. *Antidesma alexiteria* (?)—A small tree, not common in our forests. Affects rather the skirts of cultivated land. It never reaches a size sufficient to render it fit for purposes of carpentry.

15. *Artocarpus hirsuta*, *Pat funnus*, *Hebul-soo*.—Is not found in our northern jungles; sparingly in those south of the Savitree, to the bounds of Sawunt Warea; after which it is found more plentifully, and continues abundant all down the coast. Wood valuable for canoes, and can bear exposure under water.

16. *Artocarpus integrifolia*, *Funnus*.—Is with us common only about villages. Rare in the North Konkun, but most common south of the Savitree Creek. It is always planted, and often carefully manured. Under these circumstances it attains a great size. I have seen pillars of it in the interior of the buildings of the old forts at Severndroog and Rutnagherry, having 4 feet on each side.

17. *Atalantia monophylla*, *Mahkur limbo*.—Is one of the most common trees in our greenwood jungles or Raes about the Ghauts; less common below and inland. The wood has the qualities ascribed to it by Dr. Wight, but is never procurable in pieces which would square more than four inches.

18. *Azadirachta Indica*, *Neem*.—Found in considerable abundance in most parts of the inland country; more seldom as a forest tree than in waste places. In bare districts, the wood is of great importance for building and agricultural

## FOREST TREES OF WESTERN INDIA.

purposes. The leaves and bark are also highly medicinal. This is one of the trees which it would be important to increase throughout the country. It reaches a large size even in stony ground.

A B

19. *Balanites Aegyptiaca*, *Hingun bet.*—Tree common in waste places rather than in forests. Wood small, and otherwise worthless, decaying rapidly.

20. *Bassia latifolia* & *B. longifolia*, *Mhowa.*—The first of these is common in all our jungles, both on the coast and above the Ghauts; the latter I have not seen north of the Goa border. The uses of the flower and fruit, being well known, need not be enlarged on here. The wood, particularly the large logs brought from the Barria Forest and Kupperwunje Hills, is extensively used for house and cart purposes in Guzerat, but seldom appears in the market in Bombay or elsewhere. It appears strong and tough.

21. *Bauhinia acuminata*, *Duola kunchun.*—Two species appear to be mixed up here, viz. *Bauhinia albiflora*, which reaches a fair size, and *B. acuminata*, which is a small shrub, of no account as a wood. That of the first species is of good quality, but seldom of scantling sufficient for cabinet and house purposes. The other appears too small to be turned to any purpose of utility. *B. alba* is found in forests on the coast, but rarely. It is more common in the vicinity of villages. *B. acuminata* I have not met with, except as a cultivated species. It seems not to be indigenous with us.

22. *Bauhinia parviflora*, *Apta.*—Wood is reckoned very strong, but is never found of a good size. Bark excellent for ropes. Leaves are extensively used for making "Bherees," or Native cigars. Tree is found throughout our forests, both on the coast and inland.

23. *Bauhinia variegata*, & *B. tomentosa*, *Kunchun.*—The former of these is sparingly found in our forests, and never reaches a size fit for 10-inch plank. Wood is hard and good. *Bauhinia tomentosa* I have never seen in our forests.

24. *Bignonia Indica*, *Tetoo.*—Common near water streams, chiefly below the Ghauts. Wood is of no value, neither does it ever reach any size.

25. *Bignonia quadrilocularis*, *Wurrus.*—Tree found only in the higher hilly places of the Konkun, and about the Ghauts. Flower very beautiful. Wood is reckoned strong and servicable, both for beams and for planks. It is much used as planking for carts.

26. *Bignonia undulata*, *Rukt rora*, *Khew (of Sind).*—This tree is found very rarely in our forests. I have only as yet ascertained its existence in the northern parts of Baglan, in Khandeish; in Sind it is more common in some of the valleys of the Pabb Hills. and at Shah Bilawal. The wood is reckoned very strong and

durable, but, from its size, applicable only to small purposes.

27. *Bignonia xylocarpa*, *Khurseng.*—Common in forests both inland and on the coast. May be easily distinguished by its peculiar rough pods, 2 feet or more in length. The wood is good if ripe. It also affords an oil, obtained by a simple process of reverse distillation, and said to be of great efficacy in cutaneous affections.

28. *Bombax malabaricum*, *Saeer*, *Saeree*, *Kanta saer.*—One of the most common trees in our forests, both of the coast and inland. Reaches a great size. The planks are extensively used in making the light packing-boxes used in the export of bulky goods from Bombay and other places; also for fishermen's floats when the *Adansonia* is not at hand.

29. *Borassus flabelliformis*, *Tar*, *Palmyra.*—Is with us common only in the Northern Konkun, in some parts of which, especially near the sea, it is so abundant that it might be termed forest. The wood, protected from moisture, is very strong and durable, and hence may be used with advantage as roofing for terraces, &c. when the upper covering is complete. It is a rare tree in the southern jungles of the Presidency.

30. *Briedelia spinosa*, *Asun*, *Asanna.*—Rather a common tree in our forests, both coast and inland. The wood is strong and tough. Stands the action of water well: hence it is often used for the frames of wells, whereon the superstructure of masonry is erected. This wood deserves, in my opinion, to be more extensively known than it is. It is also used as beams for houses.

31. *Buchanania latifolia*, *Char*—*Charolee*, *Char.*—A straight-growing tree, and wood rather strong. It is more common in the inland than in the coast jungles. Is seldom found of thickness more than sufficient for posts. Fruit tastes like an almond, and affords a fine oil.

32. *Butea frondosa*, *Pullus.*—The tree is common in forests,—more so in those inland than on the coast. In the former localities, especially in Guzerat, it may be seen covering almost the whole of the uncultivated country. The wood appears to be little used in the Konkun and other southern countries; but in Guzerat (where it is called Bastard Teak) it is extensively employed for house purposes, and from what I have seen of it, I deem that it is both durable and strong-grained. The roots afford a strong rope, and the beautiful red exudation forms one of the gum kinos of commerce. The flowers give a bright yellow dye.

C

33. *Cæsalpinia sappan*, *Puttung.*—Tree not indigenous with us. It is, however imported in quantity from the Palghaut jungles (?) for dyeing purposes. It grows freely in our cultivated places without any care, but I remark that the

## FOREST TREES OF WESTERN INDIA.

heart-wood is dingy, and wants that fine pinkish red which the imports from the southern forest have.

34. *Calophyllum inophyllum*, *Oondie*.—Common on the coast, growing on sandy sheltered spots close to the sea on the coast south of the Savitree. North of that river it is rarer. The wood never reaches any size, and is always crooked. A good bitter oil is furnished by the seeds. To the best of my knowledge, the poon spars are furnished by *Calophyllum angustifolium*, which is a magnificent tree in the ravines of the Southern Ghauts. In habit and appearance it is totally distinct from this species. These spars are found along the Ghauts, from the Sawunt Waree border southward, but rarely of any great size till the line of the Neelcoond Ghaut is passed.

35. *Canthium nitens*, *Our C. didymum?* *Canthium umbellatum* (Wight).—If I am right in this conjecture, the tree is a common one on our Ghauts, and, from its flowers and shining leaves, well worthy a place in gardens. The wood is small, and not to put to any use.

36. *Canthium parviflorum*.—A small shrub, found on many of the barren wastes of the Deccan, and on hill ridges. I have never seen it of a size sufficient for any economical purpose.

37. *Capparis divaricata*, *Pachounda*.—If I am right in divining the species alluded to by Dr. Wight, here is a tree not uncommon in the more arid wastes and dry hedges of the interior. I have not seen it applied to any use excepting for firewood.

38. *Capparis grandis* (?) *Our C. brevispina?* *Waghutty*.—Common in waste places inland. Wood hard, and good for turning.

39. *Carallia integrifolia*, *Phunsee*.—A handsome tree, pretty frequent in the forests of the South Konkun; not seen elsewhere. Wood hard, close-grained, and might be used in turning. It is seldom large enough for any other purpose.

40. *Careya arborea*, *Koombha*, *Wae koombha*.—A tree very common both in our inland and coast jungles. It is said to stand the action of water well, but the wood does not seem to be much used. From its being generally crooked, it may be worthy a trial for the crooked timbers of boats, cornering of carriages, &c. It is employed in the upper frame-work of wells. The bark furnishes slow-match for matchlocks.

41. *Caryota urens*, *Ghaut Palm*, *Mhar*, & *Phoenix sylvestris*, *Sindee*, *Wild Date-palm*.—I mention both of these under one head because the trunks, freed from the inner pith, are chiefly used as convenient and economical water conduits. The latter is also most extensively used for the formation of embankments, temporary bridges, and piers. The wood of No. 1 (I mean that outside the pith) is nearly as hard as flint, of which, indeed, like all the grasses and palms, it contains a considerable quantity.

42. *Ocsearia elliptica*, *Bhogara*.—A small tree, not uncommon near the Ghauts, much less so elsewhere. It is too small for timber purposes, but a distinct species, which may be seen growing at Darebae Wurgaum, off the horse road from Jooneer to Nuggur,  $\frac{1}{2}$  of a size fit for house-building. I have not seen this species elsewhere.

43. *Cassia fistula*, *Bawa*, *Bayu*, *Gurmala*.—Common in our forests on the sea-board as well as above the Ghauts. It is one of the last trees which lingers in a country recently cleared. The wood is of moderate strength, but very liable to crack after drying. The pods form a small article of commerce.

44. *Celastrus montana*, *Mal Kangunee*.—A scrubby, crooked shrub, found in barren hills, chiefly of the Deccan. The wood is sought after as a choice dunnage for roof tiles, said to last for forty years,—a duration greatly exceeding that of any other dunnage material.

45. *Cedrela toona*, *Kooruk*.—Not a common tree in our forests, but found in some of the greenwood jungles about the Ghauts, and also in the hill range abutting on the Rajpooree Creek to the south. The wood is a choice one for cabinet purposes, but is not used for any others, except for house beams, when it is procurable in quantity sufficient. In the Raees of the South Konkun and Lower Canara the tree is more common. It is, in as far as I am aware, never found inland.

46. *Cluytea collina*.—This tree is not found, in as far as I have seen, within our limits.

47. *Chickrassia tabularis*, *Pubha*, *Pabha*.—A fine straight-growing tree, rather common in the southern jungles, but much less so in the northern. Wood is valuable for cabinet and house purposes. It furnishes one of the Deodars of Malabar. Could be readily creosoted.

48. *Chloroxylon swietenia*, *Satinwood*, *Hulda*.—With us I have never seen it reach beyond the size of a small tree, which, when straight (seldom the case), would afford a log squaring three inches. It is rare, being, in as far as I have seen, found only in the Padshapoor jungles, and in those of the upper Mool, in the Ahmednuggur Collectorate. In the coast forests I have never seen it. The wood is heavy and strong, and reckoned very excellent for pieces of agricultural implements. I have not seen it used in cabinet-work in the Bombay territory.

49. *Chrysophyllum acuminatum*, *Tarsee phul*, *Sapotaceæ* in *Gutta Percha* family.—Of this tree I have only heard as existing in some of the Ghaut jungles of our Southern Konkun, but have never seen it except in the Upper Canara and Soonda forests, where it is rather common. The wood seems straight and good, but the tree is chiefly noticeable from the Gutta Percha-like incrustation common on the fruit.

50. *Cinnamomum iners*, *Ran dalcheenee*.—The

## FOREST TREES OF WESTERN INDIA.

tree is found only in our Ghaut forests, chiefly to the south. The wood is rather strong, but is little used in house-building, or for implements.

51. *Conocarpus latifolia*, *Dawura*.—Varies in size from a scrubby shrub to a great tree, according to soil and situation. Seems to be as common in the inland forests as it is in those of the coast. The wood is well described by Dr. Wight as very strong. It is also tough, and hence is much in use for the wooden axles of carts. It is much used in agriculture and house-building. This also is one of the trees which should be largely increased.

52. *Cordia Rothii*, &c. *Bokur*.—The different species or varieties noticed here do none of them give a timber fit for anything but firewood. They are not uncommon in the forests, but are more generally met with near cultivated lands and villages.

53. *Cratæva Roxburghii*, *Kurwan*, *Koomla* (?).—Not a common tree. I have not seen it in forests. The wood is white, and (I believe) one of those used for the purposes of the turner.

54. *Cupania canescens*, *Ambu curb*.—Tree common in the upper Ghaut jungles. Wood of average quality, but does not bear exposure. I have not seen it elsewhere.

55. *Cullenia excelsa*.—I have not met with this tree within our bounds.

### D

56. *Dalbergia latifolia*, *Seesoo*, *Seesum*.—Is rather common in most of our coast forests, particularly in ravines of the hills and under the Ghauts, also on the Ghauts; but with us it never reaches the great size which it attains in Malabar. It is also often crooked. The wood is extensively used for cabinet-work, knees of vessels, agricultural implements, combs, &c. It appears, in density of grain and endurance, much superior to the Sissoo of Hindoostan.

57. *Dalbergia Ojienensis*: *Tewus*, *Tunnus*.—Found both in the Konkun and inland forests; especially common in some parts of Kolwan, Khandeish, and the Satpoora Hills. It is a wood of great strength and toughness, especially applicable for cart-building, ploughs, &c. Seldom reaches a size sufficient to give a plank of 9 inches.

58. *Dalbergia paniculata*, *Phassee*.—A tree rather common in most of the forests, both of the coast and inland. The wood is light yellow, strong, compact, and fit for many purposes in house-building, agriculture, &c.

59. *Dalbergia sissooides*.—I do not recognise this as being with us a species distinct from *Dalbergia latifolia*.

60. *Dichrostachys cinerea* (?) A small scrubby tree, common in waste places of the inland country; I have not seen it near to the coast. The wood is good for pegs, but too small for any other purpose.

61. *Dillenia-pentagyna*, *Kurmul*.—A great tree, common in the Konkun and Ghaut jungles; never found inland. I do not find that the wood is used for any purpose more important than for the loose planks used in the decks of Native boats. It is not employed in house purposes.

62. *Diospyros cordifolia*, *Goundun*.—Not uncommon, but more in ravines and waste places than in forests. I have never seen a tree that would turn out a log 4 inches square. The wood is strong and durable.

63. *Diospyros melanoxylon*, *Abnoos*.—The Ebony tree. I have not seen it in any of the Bombay forests. It is found sparingly in those of North Canara, as below the Woolwa Ghaut, and near Meerjan, inland.

64. *Diospyros montana*, *Teemroo*, *Teemboornie*.—Heart-wood dark and strong. Fitted for agricultural implements, in-door work, &c. Does not bear exposure. Could not be creosoted. Tree very common in our larger jungles, both near the coast and elsewhere. Fruit rather palatable. It would be one of the most common of our mountain trees if allowed to grow; but it is generally cut off for burning material, or such like worthless purposes.

### E

65. *Ehretia ovalifolia*, *Gundun*.—The tree is found about towns, never in forests. The wood is of no account.

66. *Elæodendron Roxburghii*, *Bootkus*.—I have never seen this tree, which is more common in the inland than in the coast forests, of a size fit for timber. The wood is strong and compact.

67. *Eriodendron anfractuosum*, *Shameula*.—Not common, save in some parts of Khandeish. Wood is worthless.

68. *Erythrina Indica*, *Pangara*, *E. suberosa*, *Ran pangara*.—A common tree in all parts of the country, but more so on the coast. Its place in the forests is generally taken by *Erythrina suberosa*. I am not aware that it is applied to any purpose except the making of sword-scabbards. For these it is a first-rate material, and may be exported to Europe so soon as the eyes of the military public shall have been sufficiently opened to the necessity of sacrificing clank and shine to utility in the matter of sword-scabbards.

69. *Eugenia caryophyllata*, *Rat jambool*.—Is hardly found north of the Savitree. South of that river it is found only in Raees or green-wood jungles, and about temples. The wood appears quite equal to that of the common Jambool.

70. *Eugenia jambolana*, *Jambool*.—Found in all our Ghaut and coast forests; also pretty extensively near villages, when it has been planted. I think Dr. Wight under-rates the quality of the wood. It makes excellent beams, but, on account, probably, of its brittleness, is never cut

## FOREST TREES OF WESTERN INDIA.

up for cabinet purposes. The bark affords a large supply of kino extract.

71. *Euphorbia tirucalli*, *Seyr, Teg, Unarmed milkbush*.—The wood of this, when mature, is reckoned very strong, and durable when not exposed to wet. It is extensively used, whenever procurable, as a dunnage material for the flat roofs of houses. It is sufficiently close-grained to be useful to turners. Could, I think, be readily creosoted, but is very seldom of scantling sufficient for sleepers.

72. *Euonymus garcinifolia* (?).—A small tree, growing near to the Ghauts in the upper country to the south. It seems to be often cultivated in Canara, on account of its straightness, as applicable for house rafters. It does not reach a size sufficient to fit it for general purposes.

### F

73. *Feronia elephantum*, *Kowith, Kowta*.—The tree is most common in inland jungles, but grows well everywhere. In Guzerat it attains a good size. The wood is used in building, and could probably be creosoted, so as to bear exposure.

74. *Ficus t'siela*, *Datira*.—Timber not of any account; rather common in the ravines of the Ghauts, but not in open forest land.

75. *Flacourtia montana*, *Ran tambut, Uttuck*.—A tree common in forests above and below the Ghauts, but does not, in as far as I have seen, extend inland. The wood is rather strong and close-grained, but the girth is never such as to render it sufficient for general purposes of carpentry or building.

### G

76. *Gardenia turgida*, *G. montana* (?).—I do not recognise this species or variety; neither do I find it noticed in Dr. Wight's Prodrum. If it be our *Gardenia montana*, the tree is rather common in the coast and inland jungles. It may be recognised by its straight stem, long stout thorns, and general absence of leaves. The wood is hard, but always small, never squaring to more than 3 inches.

77. *Garcinia glutinifera*.—I believe that a *Diospyros* must be here meant. It may be that our *Garcinia sylvestris* is alluded to. If so, the tree is one common in the Southern Konkan, Malabar, and Canara; always planted; affording a good wood and palatable fruit, from the kernel whereof is extracted by boiling the vegetable concrete oil "kokum." The dried fruit is a common ingredient in Native cookery, having an agreeable acid.

78. *Garuga pinnata*, *Kooruk*.—Common in our jungles. Wood appears of little value; might be creosoted.

79. *Givottia Rottleriformis*, *Reetha*.—Found only in a very few of our Bombay jungles, and in these only inland above the Ghauts. Not seen in Guzerat. The wood is light, and, in as far

as I know, used only for making the figures and models manufactured at Gokak, in the Southern Maratha Country.

80. *Gmelina arborea*, *Shewun*.—A large tree, not very common; found more in the forests below the Ghauts than inland. The wood is in much esteem for carriage pannels, and other purposes. According to Dr. Roxburgh, it also stands exposure to weather and water well. From its great size, straightness, and general speciousness in appearance (being a beautiful flowering tree), this is one of the most desirable for propagation throughout the country.

81. *Gmelina asiatica*, *Kanta, Shewun*.—This shrub I have not seen put to any use, excepting as a part of a fence.

82. *Grewia tiliifolia*, *Damun*.—This is a common forest tree in the coast jungles; rare inland. The wood is not of any value for household purposes, agricultural implements, or cabinet-work. The bark gives a strong rope.

83. *Guatteria cerasoides*, *Hoom*.—A tree common in our coast and Ghaut forests; less so inland. May be easily recognised by its great straightness, and handsome appearance. Wood is useful in carpentry, as well as for naval purposes, as boat-masts, small spars, &c. It is reddish and close-grained.

### H

84. *Hardwickia binata*, *Anjun*.—I have seen this tree only in some parts of Khandeish, and in the Padshapoor jungles. The wood is darkish colored, close-grained, very strong, and serviceable. As the shoots grow up very straight, it is also valuable for rafters.

85. *Holarrhena*.—I have not found this tree in our jungles, therefore cannot speak of it.

86. *Hydnocarpus inebrians*, *Kowtee*.—The wood is not used for any purpose. The seeds of the fruit afford an oil. The tree is hardly found in our northern jungles on the coast; more frequently in those south of the Savitree river.

87. *Hymenodction obovatum*, *Kurwe*.—The remarks made on *H. utile* apply here. We have the two species, but the wood of neither is fit for anything but fuel.

88. *Hymenodction utile*, *Kurwe*.—I cannot learn that the wood of this tree is ever used, except for firewood. The tree is common enough, in rocky slopes mostly, in or near thick forest. It does not stretch inland beyond the limits of the Ghaut ravines.

### I

89. *Inga xylocarpa*, *Jamba, Yerool (Canarese)*.—Is not uncommon in our sea-board forests south of Panwell, but not to the north. It never with us seems to grow straight to any size, so that it could be applied to house or ship-building. The wood is of a superior quality, and, in the Madras province of North Canara, is most

## FOREST TREES OF WESTERN INDIA.

abundant, particularly between Sircee and Yelapore.

90. *Ixora parviflora*, *Koora*.—Tree is common in the coast jungles, but seldom sufficiently long or straight for household purposes. The wood is rather of good quality. It is more used for torches than for any other purpose.

### J

91. *Jambosa salicifolia*, *Pan jambool*.—A crooked species of Jambool, growing much in the rivers of the Deccan country and Konkun. The stem is generally useless for house purposes, on account of its crookedness, but the straight shoots are eagerly sought after as rafters.

### L

93. *Lagerstræmia microcarpa*, *Nauah*, *Bondara*, *Benteak of Malabar*.—I think Dr. Wight under-rates the quality of this wood. It is very fit for many household purposes, and for the decks of ships, &c. It is very common in our forests, but less so to the north of the Savitree than to the south of that river. It is much used in the Dockyard, which forms a good presumptive proof that the wood cannot be very inferior.

94. *Lagerstræmia regina*, *Mota bondara*.—Timber is reckoned rather good, and is used (being generally crooked) for the knees, &c. of Native boats. It is common in the jungles, below the Ghauts south of the Savitree river; hardly found north of that, and never in the inland jungles.

95. *Limonia alata* (?).—Is found only in our southern Ghaut forests, above and below. The wood has all the qualities attributed to it by Dr. Wight. It is not a common tree.

### M

96. *Mangifera Indica*, *Amb*.—A very serviceable wood for plank when not exposed to wet. It is much used for house purposes, much less for carts. It seems to bear the action of salt-water better than that of fresh; hence is used for canoes. Could be readily creosoted.

97. *Melia azadirachta*, *Neem*.—The Garden Neem; our *Melia sempervirens* I take to be the one here meant. The wood is worthless, except for cabinet-work, for which it is fitted by its colour and grain.

98. *Melia bukaen*, *Bukhun*.—Differs from the foregoing in several respects. I have seen it only in the upper country. Though very similar to the last in leaf, and general appearance, the smoothness of the bark and smaller size of the fruit at once indicate a distinction. The tree is found only about cultivated holdings. The wood is very strong and valuable for beams, roof-dunnage for terraces, and many other purposes. It has also the useful property of shooting from the root when once cut down with as

much vigour as teak does. It is a tree deserving of extensive increase.

99. *Melia superba*, *Neembara*.—A great tree, not uncommon in the Konkun jungles, but not seen elsewhere, except occasionally in Guzerat. Used in the making of frames for native drums. The wood is of good quality, but inferior in strength and durability to that of *Azadirachta Indica*, the common or mountain Neem.

100. *Memecylon tinctorium*, *Kurpa*, *Anjuna*.—A tree of rather a small size; common on the Ghauts above; not seen elsewhere. Wood is very strong, and tough. Does not yield readily to wet. Is much employed, when procurable of sufficient size, for agricultural implements, cart-furnishing, &c.

101. *Mesua ferrea*, *Nag champa*, *Pynaroo* (?) *Malabar name of a second species*.—Tree never reaches any great diameter, but the wood is very strong and tough. I have not seen it in forests, but much about villages and Brahmins' gardens to the south. The latter species, *Pynaroo*, gives one of the finest woods I have seen.

102. *Michelia Nilgirica*, *Michelia champaca*, *Peela champa*.—This tree I have not seen wild in forests. In gardens and about dwellings it is common. The wood is straight, and moderately close in grain. It could be turned to account in house-building, and might with advantage be creosoted, but it is not sufficiently common to be extensively used.

103. *Mimusops elengi*, *Bukool*.—Mostly found as a cultivated tree; more rarely wild, and then only below the Ghauts. I have used the wood for cart shafts, and found it strong, and rather durable.

104. *Mimusops hexandra*, *Keernee*.—This tree is common in Guzerat, where it reaches a great size. It is seldom found in our forests. The wood is rather strong, and much used for well-frames in Guzerat. I have not seen it used elsewhere. Fruit is nutritious and palatable.

105. *Morinda citrifolia*, *Al*, *Bartondie*.—Not a common tree in our forests; more common about villages. The wood makes tolerable plank, but appears never to be used, except for door-shutters and such like.

106. *Myristica cinerea*, *Ran jaeophul*.—A great and straight tree, found in green-wood jungles or Raees above and below the Ghauts. It is not sufficiently common, nor found generally in situations easy of access, so as to allow of its being used for household or agricultural purposes. The wood is white and compact.

### N

107. *Nauclea cordifolia*, *Hedoo*.—A common tree in our coast forests; straight, and of large size. Never found inland. The wood is most extensively used for all purposes of planking in in-door work. Painted, it appears to stand expo-

## FOREST TREES OF WESTERN INDIA.

sure to the weather for years. Could probably be creosoted to advantage.

108. *Nauclea parviflora*, *Kuddum*.—Rather a common tree in the coast forests; less so inland. Is found, however, in quantities in the dells above the Ghauts. The wood is reddish coloured, close-grained, and rather valuable for gun-stocks, in the making of which it is chiefly used. This wood could not be easily creosoted.

109. *Nephelium longanum*, *Woomb*.—This tree is confined to our Raees or green-wood jungles, in and below the Ghauts. It is never used, in as far as I have seen, either by the carpenter or the agriculturist. In fact it is too rare to be so.

110. *Nerium antidysentericum*, *Duola kooda*.—A very common shrub in waste places, and on hills all over the South Konkun. Less so in the North Konkun and interior, but still common. The wood is hard, and fit for the turner. It never reaches a size sufficient to render it fit for the carpenter. Experiments on the bark of this tree are sadly wanted with us.

### O

111. *Odina woodier*, *Mageer*.—Found in our coast jungles, but not common. I have not seen it inland. Wood is, with us, of no account.

112. *Olea dioica*, *Par jamb*, *Karambu*.—A tree common on the Ghauts, but seldom below or inland above. The wood is of good strength, and might be creosoted with effect.

### P

113. *Pentaptera arjuna*, *Arjun*, *Sadura*, *White Aeen*.—A forest tree, rare in the North, but very common in the South Konkun, from Rainghur southward. It is always found in the vicinity of streams and rivers. Reaches a very large size, and is esteemed equal to the Black Aeen, though the rapidity of its growth would hardly countenance this opinion. The bark is justly celebrated as an application to wounds.

114. *Phyllanthus emblica*, *Aonlee*.—Tree is pretty common, both inland and on the coast. Wood is rather durable, but seldom obtainable sufficiently straight, except in gardens, where it is often grown.

115. *Pongamia glabra*, *Kurunj*.—Of this wood I cannot speak from experience, but from its look I think it may be of some use for household purposes. The tree is common in forests chiefly, near and under the Ghauts, and will generally be found skirting streams. The bitter oil is much used in the manufacture of Native felt, and has great curative powers in itch and mange.

116. *Premna integrifolia*, *Chamaree*.—The remarks made in regard to *P. tomentosa* apply here. The shrub is rare, save about the Ghaut heads.

117. *Premna tomentosa*, *Chumbara*.—I have not seen the wood of this small tree brought

into use for any purpose. It is found, but is not common, in and about the Ghauts.

118. *Prosopis spicigera*, *Soundur*.—A tree common both in waste places and forests. With us it never reaches a size which would afford a square log of more than 6 inches on each side. In Sind, where it is common, it reaches a large size. The heart-wood is very strong, tough, and dark coloured. In Sind it is commonly used for weavers' shuttles. This is the chief tree worshipped at the Dusera festival.

119. *Pterocarpus marsupium*, *Beebla Honee*.—Not common in our forests, but most so in the northern inland ones, and also in those of the extreme south, as in the Bedee Talooka. Reaches a great size, and the wood is much used in house-building. It does not stand exposure to wet.

120. *Pterocarpus santalinus*, *Rukt chundun*.—Of the qualities of the wood of this tree, not indigenous with us, but found in Malabar, I cannot speak from personal experience, and I will be glad to be furnished with further information.

121. *Putranjiva Roxburghii*, *Jeewunpootr*.—It is not common as a forest tree with us, and is found only in the coast jungles. I have never seen it of any size, but the wood appears hard, strong, and durable. It is a good wood for turning.

### R

122. *Randia dumetorum*, *Gehela*.—One of the most common trees in all our forests, but the wood never reaches any size. It is strong and hard.

123. *Rhus Buckiamela*.—Not found with us. The chief representative of this tribe in our barren hills is *Rhus mysorensis*, a scrubby shrub, fit only for firewood.

124. *Rottleria tinctoria*, *Sendree*.—A tree common both in the inland and coast jungles. Wood is of fair quality, when not exposed to wet. It is not readily attacked by worms.

### S

125. *Salvadora Persica*, *Peeloo*.—I am inclined to think that the wood of this tree is well worthy of more extended trial, as it seems rather strong, and of compact grain. It is not a tree common on this side of India Proper, except at Musulman Durgahs and places of worship; also wild on the coast in the Hubshee's Country, and in the Southern Maratha Country, and seldom reaches any size. In Sind it is more common, and grows considerably larger.

126. *Santalum album*, *Chundun*.—Appears to grow wild anywhere with us, and may be seen in quantities in waste gardens, and even in some of our grass preserves. It is said the wood has not the high qualities of that found in the more southern provinces. In the Dharwar Collectorate there are about 153,000 trees,—a number which

## FOREST TREES OF WESTERN INDIA.

much exceeds that found in the whole length and breadth of our more northern provinces. From the facility with which the tree is raised, and the great abundance of the seed which it furnishes, I am of opinion that its extension should be kept in view. The objection taken, as to the inferiority of the wood, I do not look on as well founded.

127. *Sapindus emarginatus*, *Areeta*.—This tree is often found planted, near Musulman buildings especially, but is, to the best of my knowledge, not indigenous in our forests. I have not seen the wood used for any purpose except fuel, but information is wanted regarding it.

128. *Schleichera trijuga*, *Kusoomb*.—The wood has all the good qualities described by Dr. Wight, but with us it reaches a size so large that it is used for making screw rollers for sugar-mills, cotton-presses, &c. The tree is common in the forests of the North Konkun, but less so in those of the Southern Konkun.

129. *Semecarpus anacardium*, *Beebwa*.—The tree is common rather in the skirts of than in forests, where its place is taken by another species, *Semecarpus cuneiformis*. The wood is not of any value, but might be turned to some account by being creosoted, which the openness of its fibres would admit of its being.

130. *Sethia Indica*.—This tree I have never seen. It is not found in our forests.

131. *Soyimida febrifuga*, *Rheyn*.—Vide *Swietenia febrifuga*: No remarks need be added here.

132. *Spondias acuminata*.—Sufficiently common in all the forests, both coast and inland. The wood in its natural state is not of any value, but could be creosoted with advantage.

133. *Spathodea arcuata*, *Mersingee*.—A tree common in the coast forests, but not (I think) found at any distance inland above the Ghauts. The wood is white, compact, and strong. It is, I believe, used by the turner.

134. *Sterculia balanghas*.—A tall and straight tree, common in forests of the coast. It may readily be distinguished at certain seasons by its large pink fruit. The wood is of open grain, so that it probably could, by being creosoted, be made useful in various ways.

135. *Sterculia foetida*, *Bastard Poon*.—Not common in forests, but more frequently about cultivated holdings on the coast. It grows up tall and very straight. Is used as a substitute for the true Poon spar in small country vessels.

136. *Sterculia urens*, *Kundol*.—The tree is common, both in inland and coast forests. May be always recognised by its peculiar bark, looking as if painted a light pink. Wood is worthless. Leaves and tender branches of great use in certain cattle diseases.

137. *Stereospermum chelonoides*, *Padul*.—I have never seen any reason for the opinion of Dr. Wight as to there being two varieties. We

certainly have only one, bearing beautiful fragrant pinkish flowers. The tree is not common in forests, but is found especially in those of the coast and Ghauts. I have not seen it in the inland jungles. The wood is good for interior building, but seldom procurable of a size fit for anything but posts.

138. *Stereospermum suaveolens*, *Padeel*, *Purrul*.—A tree very rarely found in our forests. May occasionally be seen in the Konkun near a temple; evidently planted for the sake of its beautiful flowers. It abounds in the Soonda forest. The wood is strong and serviceable.

139. *Strychnos nux vomica*, *Jehr katchura*.—Common in the South Konkun, particularly in shady ravines. Does not appear either north of the Savitree, or inland. The wood is reckoned of average quality, and could readily (to all appearance) be creosoted.

140. *Strychnos potatorum*, *Neermullie*.—Is with us found only in a few localities. I have seen it in the hills of the Satpoora Range near Arrawad, and in the jungles of Doodi, on the Gutpurba.

141. *Symplocos racemosa*, *Hoorra*.—Found only in the jungles of the highest Ghauts. Yellowish wood, but appears strong and compact. It might be used in cabinet-work, as well as for other purposes.

142. *Swietenia febrifuga*, *Rheyn*.—The wood is reckoned strong, and good for indoor purposes, but not adapted to those requiring exposure to sun and weather. The tree is chiefly found in the northern forests, and is more common in those inland (as about the Satpoora Hills) than in the coast forests. The wood is chiefly used for cabinet purposes. The bark is deemed (as the name implies) to have some virtue as a remedy in fevers.

## T

143. *Tamarindus Indica*, *Cheetz*, *Umlie*.—Is not a tree common in forests, but very much so near old temples, gardens, &c, where it has been long ago planted. The heart-wood is very strong and durable, but carpenters are very unwilling to work it up, on account of the great damage it causes to the best tempered tools.

144. *Tectona grandis*, *Teak*, *Sagwan*, *Sa-ya*.—The representative of the oak in India. In strength it is, as Dr. Wight observes, inferior to some other trees, of which *Dalbergia oojenensis* or *Tunnach* may be mentioned as one. In general qualities, however, and especially in endurance under exposure, it seems superior to all other Indian woods. Differences in quality, according to latitude, soil, or situation, are very observable. It is commonly said that northern Teak is superior to that of Canara; that this again is of greater strength and endurance than the Malabar wood; and that the Teak of Pegu is the worst of all. For this distinction there is

## FOREST TREES OF WESTERN INDIA.

some foundation, but I think by no means to the extent named. I have seen some Teak, grown in the richer valleys of the northern Dang, inferior in strength and compactness of grain to that imported from the inland hilly parts of the southern peninsula, as the Annamala Forest, situated between Coimbatore and Malabar. There is, however, no doubt but that the eastern Teak, from Salween and other rivers, is considerably inferior in strength and durability to that of Malabar.

145. *Terminalia alata* (?) *Pentaptera paniculata*, *Keenjul* (?)—I believe that our Keenjul is here meant. It is common to the south, but not known to the northward. Wood is equal to the common Aeen. The *Aurora* cruiser was built of this wood.

146. *Terminalia belerica*, *Yehela*, *Berda*.—A large and fine-looking tree, found in all our jungles, both on the sea-board and in the interior. Wood is worthless for building houses and canoes, as it is very readily attacked by worms.

147. *Terminalia belerica*, *Berda*, *Yehela*.—Is one of the largest trees in the forest. Found abundantly both in the inland and coast jungles. Although straight, and of great scantling, it is quite useless as a building timber, being immediately attacked by worms.

148. *Terminalia catapa*, *Bengali badam*, *Bengal almond*.—This tree is not indigenous to the Bombay Presidency, but is common in the gardens of Europeans and Natives. The wood does not appear to me to be of average quality, or fit either for domestic or public purposes, excepting for firewood.

149. *Terminalia Berryi*.—This tree is not indigenous with us, neither are there as yet any specimens of it in the Botanical Gardens.

150. *Terminalia chebula*, *Heerda*.—With us in jungles more rare than on high table-lands, on and near the Ghauts. The wood is strong, and rather hard, but on this side of India does not reach any great size, and is generally gnarled, owing to the exposed situation in which it grows. I am of opinion that in describing it as a most gigantic tree, Dr. Wight must have confounded the wood of *Terminalia belerica* with that of this tree.

151. *Terminalia glabra*, *Pentaptera glabra*, *Aeen*, *Mairtee*.—Is the well-known Aeen, found most abundantly in all our coast jungles, and also in those above the Ghauts. Valuable for house-building and many other purposes. The wood burned appears to yield very pure lime.

152. *Thespesia populnea*, *Bendie*.—This tree is found only on our coasts, and in districts near the coast. It seems to have been introduced from the Eastern Islands by the Portuguese. The ripe timber is very strong and durable, with a colour like Mahogany. It is much used in the construction of cart-wheels, and the timbers of

Native boats. The shoots are also in extensive use as rafters for houses, and at all times fetch a good price when sold for this purpose. It is, as Dr. Wight observes, very difficult to find an old tree not hollow and decayed. Government have now an extensive Bendie plantation at Sakuria, in Alibagh, and at Sat Tar. The tree grows most readily from cuttings.

153. *Trophis aspera*, *Kurrera*.—More common in Guzerat than in other parts of the country. It is rare in forests. Wood is reckoned of good quality for small purposes. It will seldom be found to square above 4 inches.

### U

154. *Ulmus integrifolia*, *Wowlee*.—Wood is rather good, but does not bear exposure well. Could probably be creosoted. Tree is rather common in the Konkun, but less so in jungles than near to villages and towns.

### V

155. *Vitex altissima* (?)—I am not sure as to the species which Dr. Wight had in his eye when he remarked on this. We have two varieties of the tree: form the first, *Vitex leucoxydon*, not uncommon by the edges of streams in the South Konkun, and the Ghaut jungles; the other *Vitex alata*; rare. Both have a white compact wood, apparently good for turning, as well as for cabinet-work.

### W

156. *Wrightia tinctoria*, *Kala kooda*.—A small tree, very common in all our forests. Wood close-grained and white, as described by Dr. Wight. Leaves are said to afford an indigo. Hence the name. It is extracted by sealding.

### Z

157. *Zizyphus glabrata*, *Ran bor*.—Wood close-grained and good. Bark affords a quantity of kino-like gum, both by exudation and by decoction. The tree is most common in cultivated lands, and in alluvial soil on the banks of rivers. It is less common on the coast than inland.

158. *Zizyphus jujuba*, *Bor*, *Bher*.—I have failed to find any specific difference between the wild and this the more cultivated species; therefore the remarks made in No. 157 may apply here. The wood often reaches a large size, fit for planks or sleepers, for which latter it might, in the dry climate of Sind (where the tree is common), answer well. *Zizyphus xylocarpa* (Gol Bor) is another species, which makes excellent torches, but is fit for no other use.

159. *Zizyphus anoplia* (?)—This shrub I have never seen but as a climber. The bark affords a good deal of kino.

160. *Zizyphus xylocarpa*, *Got bor*.—The tree is very common in the coast jungles, but I have not seen it inland. It is, in as far as I have seen, useful only for torches, for which it is valuable; the fruit burned forms the base of a good blacking material.—Dr. Gibson *ut supra*.

## FORESTS OF NAGPORE.

It will, says Captain Sankey, be clearly seen from the remarks on Statement II. that a gap in the supply of teak timber, at a low price, will probably occur between the years 1858 and 1882 (6 years being the supposed limit of the capabilities of the present source and 30 years being the time required for the Koomerponi jungle to attain its full and proper growth,) and, that it will be for the interest of Government to employ in a great measure jungleground, (particularly Eyne, Arjoon, and Bejasar from the Deogur, and Jobnee jungles,) during the interval, I hope I have placed on sufficiently strong grounds; vide Statement VI. But again, the supply of jungleground will probably prove insufficient in quantity. It is to this point that I am anxious to draw particular attention; for the Chandah districts, (that part in the left bank of the Wyne Gunga) in that case, must be looked to for a supply of teak. There, according to all accounts, almost boundless forests of the finest timber exist. The means of transport, offering itself in the broad stream of the Wyne Gunga, are at hand, and nothing but accurate information is required about localities. That no such information is at present to be had is clear, from the country being written "unknown" on the very best charts; all apparently known is that Boojung Row's Zemindaree is inhabited by a wild race of men. Even the position of Panawarras, the place where my present supply comes from, was only hit upon by chance after very great labor.

In conclusion I have only to say that should my services, in examining the Chandah jungles during the next favorable season, (they are only open from all accounts for two months in the year) and laying down the longitude of points in this unknown district, be deemed available, I would gladly undertake the duty, with the aid of a few instruments from Madras, and two or three experienced Lascars from the Quarter Master General's Office at this station.

*STATEMENT I of names and sizes of wood procurable in the Nagpore territory, with general remarks upon grain, color, and uses, and with probable prices per cubic foot.*

Number.	Language.	Names.	Sizes procurable.				Prices per cubic foot.			
			Average.		Max.		Govt.		Bazar.	
I.	Botanical.	Tectona Grandis.								
	Vulgar.	Teak.	Length in Feet.	Girth in Feet.	Length in Feet.	Girth in Feet.	Anas.		Pies.	
	Hindustani.	Sagwan.					Anas.	Pies.	Anas.	Pies.
	Mahratta.	Sagwan.								
	Tamil.	Theakamarm								
			30	5	64	4½	7	7¼	12	0

*Obs.*—There are two varieties of teak procurable, one of a light the other of a dark color; the former is that now stored in my timber yard. It seasons quickly, apparently does not lose its essential oil, and by all accounts is a better and stronger wood than the darker variety, which, drawn from the Langee jungles, was that formerly employed in the Department. Door frames of 20 years standing on removal have been found ant-eaten, but these are the only instances of such having taken place. The natives use it particularly for the construction of bowries, (by placing rough mortised frames one over the other as in the shaft of a mine) and they say when thus emersed continually in water, it lasts in an extraordinary manner. They moreover construct all terrace roofs, ferry boats, solid wheels of bandies, &c from it, as well as use it extensively for furniture.

Number.	Language.	Names.	Sizes procurable.●				Probable Government price per cubic foot.	
II.	Botanical.	Pterocarpus marsupium.	Average.		Max.		Annas.	Pies.
	Hindustani.	Bejasar or Bejasal.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Bheulah.						
	Tamil.	Vengaymarum.	18	4½	30	3½		

## FORESTS OF NAGPORE.

*Obs.*—Bejasar has a reddish colored heart, surrounded by an outer ring of a white soft wood. This ring varies from  $\frac{1}{2}$  to 3in. in thickness, so that it may be adzed off without very much diminishing the scantling of a full grown tree. It has a very close and frequently winding grain, and is subject to numerous faults. These latter are of a coal black color, and have a charred appearance. Frequently one of 3in. diameter, and considerable length presents itself. On this account it might be a dangerous timber to use for joists. For all works where these would not signify, or would be exposed, as in rafters, bressumers, &c. &c. and generally pieces of small scantling, it would be found a most valuable timber. In strength it is much superior to teak, apparently always retains its essential oil, and, like it, door frames of 20 years standing are the only instances of white ants having attacked the red wood. From the large size which is procurable, as well as the many excellent qualities of this timber, I rank it both as a tie beam and rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Govern- ment price per cubic foot.	
III.	Botanical.	Pentaptera tomentosa.	Average.		Max.			
	Hindustani	Eyne.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Ain or Eyne.						
	Tamil.	Marudammaram.						

*Obs.*—Like Bejasar this timber has white wood surrounding the body and heart, which is of a blackish brown color; the ring however in this case does not exceed 1 $\frac{1}{2}$ in. in breadth. The dark wood is exceedingly heavy, being exactly the same weight as water, and has a much more winding grain than Bejasar. In strength it is far superior to all its forest congeners, and from the strength given by Barlow for American Teak, it even appears to excel that celebrated timber. Unfortunately its length is limited, seldom furnishing more than a 20 feet tie beam, from the crooked manner in which the tree grows. It is a difficult timber to work up, splits freely when in exposed situations, and by all accounts is very subject to dry rot. The latter defect being overcome by the steeping process, and the former guarded against, I know of no timber which can bear a comparison with it; for the joists of a terraced roof it would be invaluable. White-ants will not attack it. I rank it both as a tie beam and rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Govern- ment price per cubic foot.	
IV.	Botanical.	Diospyros ebenum.	Average.		Max.		Annas.	Pies.
	Hindustani.	Tendoo.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Taimurum or Tendoo.						
	Tamil.	Toombie marum.	18	4½	20	4		

*Obs.*—When young, this tree, which yields a very fine ebony, has very little of the black wood. As it advances in age this increases, and eventually nothing but black wood is found. The white wood is that which has been experimented upon. From the ease with which it bends, the natives employ it in the manufacture of Buggies, Carriages, &c., &c., but losing its essential oil soon, the unseasoned timber is preferred for these purposes. White ants attack it readily, and it is nearly always Beetle bored. Although in strength it excels teak, yet from the above circumstance, as well as from the fact that it is very seldom obtainable of more than 6in. square, I have rejected it as a building material.

# FOREST TREES AND FORESTS OF NAGPORE.

Number.	Language.	Names.	Sizes procurable.				Probable Government price per cubic foot.	
V.	Botanical.	Gmelina arborea.	Average.		Max.			
	Hindustani	Seevum or Seeven.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Seevun.						
	Tamil.	Coommy maurum.	13	4½	18	3½	5	6

*Obs.*—The Seevum is of a very light color, has a sort of netted grain, is free from faults, and altogether may be considered a very excellent timber, although unfortunately not procurable in large quantities. The Commissariat supply it to the Ordnance Department for making packing cases, &c., &c., and the Natives employ it in the construction of palkies. It takes varnish well, and works up nicely into furniture, but is attacked readily by white ants. From the small scantling of which it is obtained, I must class it merely as a rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government price per cubic foot.	
VI.	Botanical.	Bassia latifolia.	Average.		Max.			
	Hindustani	Mowah.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Moho.	15	5	20	4	5	0

*Obs.*—The Mowah, from the flower of which the darru is made, and which is extensively spread in forest and plain, is a pinkish colored wood. It is but a weak timber, and from being invariably rotten at the heart, 6 to 4 inches square of really good sound timber is all that can be reckoned on. In the plains the tree is preserved for the flower, as well by general consent as the Rajah's orders, and consequently is very little used. In the upper Provinces I am aware that the timber is more esteemed, and has been used for door and window frames. Nothing more need be said about it (as with a profusion of fine timbers, I do not class it as a building material) except that it is eagerly devoured by white ants.

Number.	Language.	Names.	Sizes procurable.				Probable Government price per cubic foot.	
VII.	Botanical.	Terminalia chebula.	Average.		Max.			
	Hindustani	Hurra or Hurda.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Goandee.	Hurda.						
	Mahratta.	Kuducal marum.						
	Tamil.	Pilla mardah marum.	16	4½	20	4	5	4

*Obs.*—The Hurda has a yellowish colored wood which becomes very dark on the outside in seasoning, it is attacked by white ants, and is inferior in strength to teak; appears to have but little essential oil, and is said to be very subject to dry rot. Steeped in the solution of sulphur of copper, it would be of value, principally from the ease with which it works. The fruit is well known for its dyeing properties. From its not being obtainable of large scantling, I class it merely as a rafter timber.

# FOREST TREES AND FORESTS OF NAGPORE.

Number.	Language.	Names.	Sizes procurable.				Probable Government price per cubic foot.	
VIII.	Botanical.	Acacia ordoratisissima.	Average.		Max.			
	Hindustani	Sirsa.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Goandee.	Chechooah or sunkœur (?)						
	Mahratta.	Sirris.						
	Tamil.	Curry vaugay marum.						
			15	3	18	3	5	0

*Obs.*—The Sirsa has very much the color of eyne, indeed it is only distinguishable from that wood by having a much straighter grain, and being a somewhat lighter wood. It has a ring of from 2" to 3" of white wood, and this part alone is assailed by white ants. The tree is for the most part found in gardens, and I have seen it attain a very considerable size, though, as a general rule only pieces of small scantling are obtainable. The teeles use it frequently for their oil mills, and by the natives generally it is employed for bandies. This although a very superior wood, must, from the small scantling procurable, rank merely as a rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government price per cubic foot.	
IX.	Botanical.	Erythrina Indica.	Average.		Max.			
	Hindustani	Paunjera.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Paunjera.						
	Tamil.	Moochoo marum.						
			14	3	17	2½	3	0

*Obs.*—The Paunjera is an exceedingly light wood, exactly ½rd the weight of water, and of necessity very weak. It is particularly applicable to many purposes for which deal is employed at home, viz. in making packing cases, &c., &c. The Natives use it exclusively for sword cases. It is eaten by white ants eagerly, and on the whole it must be rejected as a building material.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
X.	Botanical.	Conocarpus latifolia.	Average.		Max.			
	Hindustani	Thoura.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Thoura.						
	Tamil.	Vellay naga marum						
			12	3	17	2	5	6

*Obs.*—This very promising timber, like many of those before mentioned, has white wood with a heart of a dark color, and somewhat like rosewood. It is so much prized by the Natives for axletrees, that but few trees are permitted to attain their proper growth. By all accounts, about 20,000 axletrees are made from this wood yearly. It is attacked by white ants. Though not obtainable in very large quantities, it ranks high as a rafter timber.

# FOREST TREES AND FORESTS OF NAGPORE.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XI.	Botanical.	Swietenia febrifuga.	Average.		Max.			
	Hindustani	Rohun.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Rohuni.	17	4	20	3½	5	0

*Obs.*—The Rohun, as a writer in the Bengal Gazette remarks, “is a mahogany furnishing a febrifugal bark, and believed to be one of the most durable and heavy woods known, and of a blood red color.” The specimens which I obtained might be called somewhat darker in color than here described.—In weight the wood is much greater than water, but by all native accounts it is far from a durable wood, splitting greatly on exposure, and when seasoned becoming extremely brittle. It nevertheless has a fine straight grain, and is not at all so difficult to work as its great weight and compactness would lead one to imagine. Notwithstanding this, and the fact that it rivals the finest English oak in strength, I hesitate to recommend it as a building material.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XII.	Botanical.	Dalbergia sissoo.	Average.		Maxm.			
	Hindustani.	Seesum.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Seesum.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Tamil.	Yette marum.	10	3	15	2	6	0

*Obs.*—The Seesum very much resembles rosewood in appearance, but is not so compact, and therefore cannot like it answer well for veneering purposes. The natives employ it extensively for ornamental work. They make combs, domes of Gharries, &c., &c., from it. The white wood, of which it generally has a good deal, is alone eaten by white ants. The dark wood never seems to lose its essential oil, and since it is of great strength, when obtainable of a proper scantling, it may be looked upon as a very valuable timber. In Chandah alone it is said to attain a large size. As it is I class it as a rafter.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XIII.	Botanical.	Acacia arabica.	Average.		Maxm.			
	Hindustan.	Bhubool	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Mahratta.	Bhabool.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Tamil.	Curvaila Marum.	10	5	14	3½	6	0

# FOREST TREES AND FORESTS OF NAGPORE.

*Obs.*—Little need be said about this well known tree, as it is relatively weak (?) grows to no great length, and is always crooked grained. The natives use the wood for the spokes and felloes of wheels, and exclusively, I believe, for drill ploughs. Though apparently white ants will not attack it, and the wood might be used on emergency, yet under the circumstances, I reject it as a building material.

Number.	Language.	Names.	Sizes procurable:				Probable Govern- ment prices per cubic foot.	
			Average.		Maxm.			
XIV.	Botanical.	Butea Gibsonii. (?)	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas.	Pies.
	Hindustani.	Dhamin.						
	Mahrata.	Dhamun.	15	2½	17	2½	6	0

*Obs.*—The dhamin has fine clear grain, is of a light color, and has many of the properties of "lance wood." From the facility with which it bends, this wood is held in great esteem for Buggy shafts. The natives use it exclusively for the bent ribs of hackary poles. From the extensive use made of it, few, if any, trees attain their proper growth. Were it obtainable of proper size it would rival the finest timber, but under the circumstances, I am obliged to place it among the list of rafter woods, and even here the small quantity obtainable, will limit its application.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XV.	Botanical.	Cedrela toona.	Average.		Maxm.		Annas.	Pies.
	Hindustani.	Thoon.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Thoon						
	Tamil.	Thoona marum.	10	4½	12	3½		

*Obs.*—As I consider this timber, with a profusion of other fine woods at hand, comparatively unsuitable for public buildings, I need merely say that it has nearly the same color as Bejasar, is much lighter and weaker than that wood, and is attacked by white ants. I have seen however some nice light furniture made from it.

Number.	Language.	Names.	Sizes procurable.				Probable Govern- ment prices per cubic foot.	
XVI.	Botanical.	Pentaptera arjoona.	Average.		Maxm.		Annas.	Pies.
	Hindustani.	Arjoon or Unjen.	Length in feet	Girth feet.	Length in feet.	Girth feet.		
	Mahratta.	Azun.	18	4½	30	4		

## FOREST TREES, AND FORESTS OF NAGPORE.

• *Obs.*—The timber of Arjoon is of a deeper red than Bejasar; perhaps it is more of a brown red. Is heavy and splits freely when exposed to the sun's rays. White ants attack it, seeming to prefer moist situations, it grows almost exclusively on the banks of rivers, and to an enormous size, but being frequently rotten at the heart does not always reward the labour of cutting. Its strength is undoubted, and consequently with careful selection, would be found valuable. I class it as a tie beam and rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XVII.	Botanical.	Dalbergia ——— ( ? )	Average.		Maxm.		Annas.	Pies.
	Hindustani.	Thevus.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Thevis.	15	3½	17	3½	6	0

*Obs.*—Thevus is a light colored wood merging into a light reddish brown. Its strength is considerable, and by the natives the wood is highly prized for bandies. White ants attack it. Little further being known about this timber, excepting that a small supply is alone obtainable. I rank it as a rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XVIII.	Botanical.		Average.		Maxm.		Annas.	Pies.
	Hindustani.	Kyem.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Kem.						
	Tamil.		16	4	28	3	5	0

*Obs.*—Kyem is of a light color, is inferior to teak in strength, and greedily eaten by white ants. I am not aware of any use to which the natives apply this wood. It will however rank as a rafter timber.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XIX.	Botanical.		Average.		Maxm.		Annas.	Pies.
	Hindustani.	Derea or Dareah.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.		
	Mahratta.	Bhera.						
	Tamil.		6½	3	10	2	6	0

*Obs.*—This wood, though of great strength, cannot, from the small size the tree attains, under the circumstances rank as a building material. I may mention, however, that it has a winding and as it were netted grain, from which, as well as the extraordinary toughness of its fibres, butchers invariably use it for chopping blocks; the sharp edge of the knife apparently having no effect on it.

# FOREST TREES AND FORESTS OF NAGPORE.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XX.	Botanical.	Nauclea——(?)	Average.		Maxm.			
	Hindustani.	Bahdali or Behra or Bhada.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas	Pies.
	Mahratta.	Hirida						
	Tamil.		15	3	17	3	6	0

*Obs.*—This is a nice clean working wood, of a yellow color and straight grain, and has apparently but little essential oil. It is very scarce, and when obtainable, used by the natives for all purposes; in strength it ranks next to cyne, and therefore, if procurable in large quantities, and of a proper size, would be a most valuable wood. I rank it as a rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XXI.	Botanical.		Average.		Maxm.			
	Hindustani.	Dhewus Dhaves.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas	Pies.
	Mahratta.	Dhivus						
	Tamil.		12	2	15	2	8	0

*Obs.*—Dhaves has a light colour, is devoured by white ants, and is only procurable of a small scantling. Its strength however is considerable, and if found of a proper size, would doubtless be valuable. The young trees in this part of the country are I understand all cut down for bandy poles. It ranks as a rafter wood.

Number.	Language.	Names.	Sizes procurable.				Probable Government prices per cubic foot.	
XXII.	Botanical.	Vatica robusta.	Average.		Maxm.			
	Hindustani.	Saul.	Length in feet.	Girth in feet.	Length in feet.	Girth in feet.	Annas	Pies.
	Mahratta.	Saul.						
	Tamil.		25	4½	60	3	16	0

*Obs.*—Saul resembling Bejasar somewhat in color, differs peculiarly from it in the construction of its grain, and in its freedom from the faults, to which the other is so subject. In strength, size, and all the qualities of good timber, it appears to me to stand first of all those procurable in these territories, as a tie beam or rafter wood; but unfortunately the price, which the difficulties and expenses of transport oblige me to attach to it, compels me to rank it very low in value. It does not appear to lose its essential oil for a long time, and always exhibits small surface cracks, which widen or contract with the change of season. Nothing further need be said about this well known and excellent timber, particularly as I believe experiments have been made on it, to ascertain how it would answer for the manufacture of Gun Carriages.

Since the experiments were concluded, two other woods, the one called *Laendia*, the other *Karee*, have been brought to my notice, as likely to give good results. The first is said to resemble very closely Thevus and to be equally good. It is probably therefore a valuable timber. In the absence of specimens however I cannot offer an opinion.

Sir Richard Jenkins in his valuable report on the Nagpore Territory, states, that "the Rall or rosin tree, as also other large wood is obtained in the forests of Kakair, (probably Conkair of my map) and in the Hills North of Rattenpore." What this Rall tree is I never have been able distinctly to ascertain, though the above statement, and some vague native reports would lead to the conclusion that it is a tree of large growth, and bearing some comparison with the Saul, for which I have heard it given as a synonyme more than once. When shortly since visiting the Pachmurra Range, Dr. Jerdon and I met with a tree of the Saul family, to which he gave the name of "Vatica Toomboogia" and which the natives say furnishes a frankincense. This is probably the Rall tree, though it does not seem in those jungles to attain a large size.

For obvious reasons I have omitted making mention of the timbers of the "Mango," the "Tamarind," the "Peepul," &c., &c., which are common to this part of the country with the rest of the Peninsula.

STATEMENT II of the probable quantities in which the useful Timbers are found in the Nagpore Territories.

Names of woods likely to answer for public works with Nos. corresponding to those in Statement I.		DEOGUR BELOW THE GHATS.		DEOGUR ABOVE THE GHATS.		WYNE GUNGA OR BUNDARA DISTRICT.		CHANDAH DISTRICT.		CHUTTEESGURAH OR RYEPURE DISTRICT.

N. B. The letters R. and T. B. here mean severally trees procurable of the sizes of Rafter and Tie Beam timber—vide Remarks, Statement VI.

## FOREST TREES AND FORESTS OF NAGPORE.

### *Remarks applying to the foregoing Statement.*

I. The Pachmurra jungles lying all about the base of the range bearing the same name, and very dense to the East and West of it, though having a great profusion of fine timber, do not apparently furnish beams of equal scantling with those situated on a lower-level. The difficulties to be contended with in clearing a path for the transport of the timbers to the Kanhan are very great: and that stream, even in the monsoon, presents so many rocky barriers, as to render it doubtful whether the beams could even then be navigated in rafts to Kamptee; and again, the expense of land carriage would put the obtaining of beams from this source out of the question.

II. The jungles line about Deogur, Jobnee, Jam, and generally the base of, and on that line of ghauts. From these hitherto the supply of jungle woods for the Department has been drawn, they furnish very fine timbers, but the difficulties of cutting and transport yearly increase from the precipitous nature of the Hills on which they grow. These Hills are for the most part trap, resting on granite, which will fully account for the circumstance. These jungles will continue to supply the Department with Bejasar, Eyne, and Arjoon for many years. Hitherto land carriage has been employed to Kamptee from the obstacles to floating which the Kanhan presents in two or three places, but a more extended communication hereafter, might warrant an expenditure sufficient to overcome these.

III. At Koomerpani a little to the East of the above, great quantities of young teak trees (estimated at no less than 15,000) have been observed; these, if carefully preserved for the next 25 or 30 years, would, after the expiration of that period, furnish nearly a century's supply for the present Kamptee demand. The difficulties of transport are at present enormous, and not worth the expense of overcoming in the young state of the jungle. But when the trees shall have arrived at their full growth, the clearing of a track to the Pench or Kanhan Nuddees, would involve an expense inconsiderable with the value of the store opened up. The price of teak thus obtained would not probably be more than 5 annas the cubic foot, which would at once raise it to the first class either as a tie beam or rafter timber.

IV. Doongerthal, more to the East and South, will yield a supply of rafter timber, and from its nearness to Kamptee at a very moderate rate. The supply is however trifling.

V. Langee, though formerly thought so much of as a place likely to yield an excellent supply of timber, has been almost completely denuded.

VI. Mundilla, from which I believe the Seonee and Jubbulpore supply of teak is drawn, though abounding in fine timber, and specially with saul, presents from all accounts too great difficulties for a supply being at present drawn from it for the Kamptee market.

VII. The Panawarras jungles, South East of Kamptee, from which my present supply of teak is drawn, are gradually getting cleared, and timber suitable for the public service can only probably be obtained for another 6 years. From the nature of the country the cutting and transport of beams is comparatively easy. Till this season we have been in the habit of carting the beams all the way to Sillapore on the Bang Nuddee there forming them into rafts and floating them with the stream to Ambora (more correctly Ghat Kooraddee), where the Kanhan discharges itself into the Wyne Gunga. With the supply however which I am now getting up, I intend trying the Koragurh Nuddee, whose ramifications I understand extend to nearly all the places where the timber has been cut. The beams after entering the Wyne Gunga, will require to be drawn up against the stream to Kamptee, but I am in hopes that the expense will notwithstanding be less than that of former years.

VIII. I have introduced the probable supply of the Raepoor or Chutteezghur jungles in respect to teak and saul (vide statement) more as a matter of curiosity, than for any useful end to which it can at present tend. The Jouk, Leo, and other Nuddees which flow into the Mahanuddee, may at a future period bring timber from the vast forest in rear to the neighbourhood of the Baugnuddy, and thence to Kamptee; but, at present, it is useless to speculate on such a case presenting itself.

IX. Boojung Row's Zumindaree, from which the future supply of teak must be drawn, is capable of affording an unlimited supply, but accurate information is wanting.

## GALLS.

(800) FELAMERZ, the son of Roostum, the hero of Persian Romance, was defeated by Behram near the fort of Fessa, between Shiraz and Darab. Behram caused Felamerz to be hanged, and his tomb existed in the village, until, it is said, a European traveller removed it away, as a relic.

## G.

(803) GABA-GABA, is the stem of the leaf of the sago palm, much used throughout the Moluccas in buildings and fencing. *Atap* is thatch made of the fringe of palm leaves, doubled down and sewed on sticks or lathes of bambu.—*Journ. of the Ind. Arch. Vol. VI. No. 6.*

### (804) GAINGOOL.

Gaingool, HIND. | Tati kengaloo, TEL.  
Panam calang, TAM.

Is the young plant or shoot of the palm tree (*Borassus flabelliformis*). It is boiled and eaten by common people. To obtain it they dig a hole, about a yard deep, in which they put the stone of the fruit and cover it up with earth: about a year afterwards it is dug out and the plant or shoot then produced is called Gaingool.

(805) GALANGAL. This root is sent from China to India; there are two sorts, the greater and the smaller, obtained from different plants, the best of which is the smaller, procured from the *Maranta galanga*. This is of a reddish color, about two inches long, of a firm texture though light, and possessing an acrid, peppery taste, and a slight aromatic smell. The larger is from a different plant (*Kempferia galanga*), and inferior in every respect. Both are used as spicery, and to some degree in Europe as well as India.—*Williams' Middle Kingdom, Vol. II. page 400.*

### (806) GALEDUPA INDICA.

Karunjuka, SANS. | and BENG.  
Kutanja or kenja, HIND. | Ganuga, TELING.

Maaphul, DUK. | Majaknee, MALAY.  
Ufesa, ARAB. | Majuphal, SANS.  
Majoophul, HIND. | *Ains. Mat. Med. p. 165.*

Some years ago in the dispensaries of Bengal, Gall nuts were tried extensively in powder with infusion of Cheretta, but the general result was unfavorable, conveying the impression that the mixture was not equal to the common country febrifuges.

The subject was brought to the notice of the Madras Medical Board in 1853, by Assistant Surgeon Timmins, in charge of the Bhopal Contingent and Agency, and the result of his treatment was that "during the 12 months, from 1st

October 1851 to 30th September 1852, the whole of the cases of Fever, with one or two exceptions in the Hospital of the Bhopal Contingent, were submitted to this treatment (gall powder and infusion of chiretta) and all yielded to it with the exception of three cases of Quartan Fever, one of Remittent and one of Continued Fever, in which the concomitant symptoms being severe, he was necessitated to employ other remedies."

The cases he treated by galls and chiretta, were 244. By quinine and other means, five average No. of days in hospital to each patient 8.95. In cases treated the previous year by quinine during a corresponding period, the average No. of days in Hospital was 9.91.—*Dr. Cornish in Indian Annals No. VII. page 115.*

(808) GAMBIR, is an Extract from *Uncaria Gambir*, and has been recommended by Mr. T. C. Drysdale, of Singapore, as a preservative of timber exposed to water, or canvas. The gambier may be in solution, in water, but if applied to ships' bottom, it should be in the form of a composition of chunam, gambier and dammar oil. It is also recommended to be applied in house building to protect the beams from the white ants, and in ship building as a composition on the butts, and on the outside of the timber previously to planking. Gambier may also preserve timber from dry rot.—*Jour. Ind. Arch.*

(809) GANDASULI. Marsden gives this as the *Hedychium coronarium* of Linnæus, and adds that its flowers are worn as ornaments in the hair, and in the enigmatical language of flowers stand for inconstancy.—*Jour. Ind. Arch. Vol. V, No. 8, August 1851.*

(810) GANGES CANAL. This is unquestionably the greatest work of irrigation ever accomplished in any tropical country at any epoch of history. It cost a million and a half sterling, nearly all of which was expended during the seven years of Lord Dalhousie's administration and the main stream was opened on the 8th April 1854. It extends over 525 miles in length; measures 170 feet in its greatest depth. Its length is five-fold that of all the main lines of Lombardy united, and more than twice the length of the aggregate lines of Lombardy and

Egypt together, the only countries in the world whose works of irrigation rise above insignificance. It nearly equals the aggregate length of the four greatest canals in France: greatly exceeds all the first-class canals of Holland put together and is greater by nearly one-third, than the greatest navigation canal in the United States of America. When completed, it will be 900 miles in length, and it is estimated that the area which may be irrigated by its waters, will not be less than 1,470,000 acres.

(811) GANONG, generally called Ayen Panas, hot springs in Nainong. All the hot springs of the Malayan Peninsula, and some of those in Sumatra, occur in swampy flats. That of Ganong occurs at or close to the line up to which plutonic action has converted the rocks of the district into granite.

(812) GARDENS. In Mr. Wilson's specimens of the Hindoo drama, there are plays called "the Necklace," and "the Toy cart," which he translated from the Sanscrit, containing beautiful allusions to gardens in India.

"The garden is now most lovely. The trees partake of the rapturous season, their new leaves glow like coral, their branches, wave with animation in the wind, and their foliage resounds with the blythe murmurs of the bee. The bakula blossoms lie around its root like ruby wine; the champaka flowers blush with the ruddiness of youthful beauty; the bees give back in harmony the music of the anaclets, ringing melodiously as the delicate feet are raised against the stem of the asoka tree."—*The Necklace, Wilson's Specimens of the Theatre of the Hindoos, Act 1, page 272.*

"Look round the garden with these stately trees,  
Which daily by the kings command attended,  
Put forth their fruits and flowers  
And clasped by twining creepers, they resemble  
The manly husband, and the tender wife."—*Toy Cart, Act 8, page 125. Specimen of the Theatre of the Hindoos, translated by Mr. Wilson. —Ibid.*

This play is supposed to be written by a King, named Sudraka; over what kingdom he reigned, it is not ascertained with certainty. This play is, however, of considerable antiquity, and Mr. Wilson remarks in his introduction to the 'Toy Cart,' page 9, that it may be safely attributed to the period when Sudraka, the sovereign, reigned, whether that be reduced to the end of the second century after Christ, or whether we admit the tradition, chronologically, and place him about a century of our era. These specimens of the Hindoo drama are certainly curious. We are struck with the little change in the customs of the Hindoos since the plays were written.—*Chow Chow, p. 218.*

(813) GEOLOGY OF INDIA. Mr. Oldham, at the request of the President, proceeded to give some account of the results he had arrived

at from the investigations conducted by himself and his assistants in the Geological Survey in Central India during the season of 1855.

Briefly referring to the many valuable papers which had been contributed by previous observers illustrative of the Geology of Central India, and to the fact that few parts of the immense empire of India had excited more interest and attention than the districts adjoining the Nerbudda river, Mr. Oldham pointed out that the great thickness of sandstones and associated beds, which formed the mass of the Vindhya range, was the most striking and remarkable feature in that country. This had been spoken of as "the sandstone," "the great sandstone, &c." Capt. Franklin had referred it to the age of the middle portion of the new red sandstone of European geologists. Jacquemont, for the greater part at least of the area, assented to this view. Other observers had given it a different position. Captain Sherwill for instance had mapped it as old red sandstone, although giving it the somewhat anomalous position of resting upon "mountain limestone." In 1854, Dr. Carter of Bombay had published a carefully compiled summary of the Geology of India, in which the whole of this sandstone and associated beds was referred to the same age as the coal bearing rocks of Bengal, all which he classed with the oolitic or jurassic epoch of European geologists, and he took his typical groups, and the names for his subdivisions from localities in this district. He divided the whole into three sub-groups, which he called—Tara, Kuttra, and Punnah groups, in ascending order; the coal being supposed to belong to the central or the Kuttra group. And this classification he applied to other districts. Again on the geological map of India, recently published under the sanction of the Court of Directors, by Mr. Greenough, all this immense area, stretching from the Soane to near Mundlairsir in the Nerbudda, was placed under the general head of oolitic and diamond sandstone and limestone.

The researches of the Geological Survey of India, had extended over a considerable portion of this district during the past season, and although much remained to be done in working out the details, as might be anticipated in so large an area, sufficient had been learned to enable a few great conclusions to be drawn. It was at present impossible to give all the detailed illustrations of these, and they would therefore be only stated as briefly as possible. The importance of them would at once be recognised by those who had given any attention to these enquiries, tending as they did to modify existing opinions, and to alter the colouring of all our geological maps in the most marked and extended way.

Their late investigations had shewn—that there was good evidence of a great faulting, accompanied

by much disturbance mechanically, and by much alteration chemically, in the rocks (more especially to the south of this fault), which passed along the main line of the Nerbudda valley, along the continuation eastward of this line down the valley of the Soane; and thence across Behar, where the continuation of the same rocks formed the Kurruckpoor hills.

That there was a high probability that this line of dislocation was continued to the east by north, up or towards the valley of Assam; its main direction being E.  $15^{\circ}$  to  $18^{\circ}$  N. corresponding with the main direction of the Vindhya range and the Khasi hill range.

That south of this dislocation the great group of sandstones, shales, &c. forming the Vindhya hills, was almost entirely absent, (unless it were admitted, see below, that the highly metamorphosed rocks there seen were the continuation downwards of the same series greatly altered.)

That this great group was altogether of a different character and of a more ancient epoch than the beds associated with the coals of Bengal and of Central India. (The latter resting quite unconformably on the former.)

That from the absence of organic remains, there was as yet no evidence on which to base a reference of this group to any established epoch of European geology. (*It might be Cambrian.*)

That the names hitherto assigned to this group and its subdivisions being based on erroneous views of position, and therefore tending to erroneous conclusions, must be abandoned.

For the whole formation Mr. Oldham proposed the name *Vindhyan*, stating that it appeared most desirable that the general *physical* relations of the rocks should be determined, and the several groups established on such evidence derived from the actual arrangement and sequence of the rocks rather than from some fancied or imperfectly established analogies derived from partially collected or partially examined organic remains. When the actual sequence of the various groups had been established, wherever this was possible, the organic evidence would be valuable. Applying the name *Vindhyan* then to this great group as being best seen in the well exposed scarps of the Vindhyan range, he would propose as distinctive of the subdivisions in ascending order, the names Kymore, Rewah and Bundair. These minor groups were only given provisionally, as it was possible that more detailed examination would shew that there was only a two-fold division, and that the Rewah limestone and Bundair sandstone were only repetitions of the Soane valley limestone and sandstone produced by faulting.

Resting unconformably upon the Vindhya formation, there was a considerable thickness of sandstones, shales and coals, (in Central India much disturbed, and traversed by trap dykes).

ceeded some thousand feet. In these beds occurred numerous fossil plants, which thoroughly identified these rocks with the coal-groups of Burdwan, of Hazareebaugh and of Cuttack. No *additional* evidence tending to settle the doubtful question of their true geological epoch had been obtained, nor on the other hand any thing to shake the probability of their Jurassic date. Taking it as proved that the strata at Kotah, from which the fish and Saurian remains had been obtained, were the same with those of Kamptee near Nagpore, the strong *Permian* analogies of the Saurians (*Brachyops*) ought not to be overlooked. But the identity of the strata was, he thought, still to be established.

Resting again quite unconformably upon these rocks was found another series of sandstones, often ferruginous, generally speaking irregularly though strongly bedded, and of great thickness. These formed the lofty and boldly scarped range of the Puchimurry or Mahadewa hills. And to this group Mr. Oldham proposed to give the name of Mahadewas. No organic evidence had been found in these. In one or two places they seemed to pass upwards conformably into sandstones holding remains of large mammalia (and probably of Sewalik date.)

This group was markedly separated from the coal-bearing group below, and as compared with it was also characterized by the comparative absence of trap dykes or other exhibitions of igneous rocks.

Upon these, in parts of the district, rested the great spreading sheets of trap rocks forming the continuation of the immense basaltic field of the Deccan. Four and five distinct flows could readily be traced in places. And adverting to the occurrence of the beds containing Shells (*Physa*, *Paludina*, *Unio*, &c.) which were found between these flows (Intertropean lacustrine formation, of Carter) *so far as the evidence derived from the Nerbudda district was concerned*, it appeared that there was no reason to suppose that they were confined to any one layer or flow, and still less reason to suppose that their present aspect and condition was due to the intrusion of the igneous rocks from below (as advocated by some), but that on the other hand there was much ground for thinking that this alteration was entirely due to the subsequent overflowing of the heated mass of the trap above, and to the disturbances consequent on the exhibition of such powerful force as must have accompanied the production of these immense flows of lava. These shelly beds seemed to have been formed by tranquil deposition during the intervals between the successive flows of igneous rock, and to have been broken up indurated and baked by the succeeding outbreak. Mr. Oldham stated, that in making this remark, he wished to say that he had not had the oppor-

## GEOLOGY OF INDIA.

Messrs. Hislop and Hunter, near Nagpore, from which those careful observers had drawn their conclusions, but that his view had been derived solely from the facts presented to him in other places.

The detailed examination of the greater part of the Nerbudda district was due to the exertions of Mr. J. G. Medlicott.

The following would therefore give a summary view of the groups here proposed in descending order, neglecting for the present all the more recent divisions.

Groups.	Mineral character.	Age, &c.
Mahadewa,...	Sandstones, with a few shaly beds, for the most part pebbly, often striped with ferruginous bands.	Geological age unknown, a few vegetable fossil stems, &c.
Damoodah,...	Shales, sandstones, coal, for the most part thinly bedded and regular, often greatly cut up by trap dykes. <i>In Out-tack however there are no trap rocks.</i>	Age not thoroughly decided probably Jurassic, fossils chiefly vegetable, name taken from the locality where series is most fully developed.
Vindhya. Bundair, Rewah,...	Sandstones and shales. Limestones, shales and sandstones,...	Age unknown, probably very ancient, seen all along Vindhya range, into Behar and to the Ganges at Monghyr. Probably also in the Khasia Hills possibly only two subdivisions.
Kymore, Sub-Kymore	Sandstones and limestones and shales,...	
	Crystalline limestone pseudo-gneiss (name proposed by H. B. Medlicott, Esq.) micaceous schists, and quartzites, red and green, and white.	Highly probable, though not yet thoroughly proved, that these are only the continuation downwards of the Vindhya groups subsequently altered.

Granite, gneiss hornblende-rock, greenstone, &c.

Another district of considerable interest had also been examined during the past season, by Messrs. Blanford and Theobald, and the results arrived at under their careful scrutiny had been strongly confirmatory of the results given above. The Cuttack, or Talchere coal-field gave the following section, descending :

*Allyvium, laterite, &c.*

1.—Upper grit series,—unfossiliferous—quartzose grits and coarse sandstones, with occasional red shales; pebbly throughout, and near base

## GEOLOGY OF INDIA.

2.—Carbonaceous shale series, fossiliferous, consisting of

(a)—Blue and lilac shales, micaceous; white speckled sandstones ironstones, about 1500 feet thick.

(b)—Carbonaceous shales containing thin seams of coal (8 inches) irregularly dispersed through them, about 200 feet.

(c)—Shales and coarse white sandstones, the latter predominate in lower portion, 100 to 200 feet.

(3)—Lower shale and sandstone series, annelid tracks, consisting of

(a)—Blue nodular shales, generally arenaceous.

(b)—Fine sandstones, much jointed and "tesselated."

(c)—"Boulder bed," containing numerous boulders of gneiss and granite frequently 5 to 6 feet across—in a fine argillaceous or arenaceous rock, often rippled, sometimes replaced by a coarse sandstone.

Each of these series rested unconformably on that beneath it.—*Beng. As. Soc. Jour. No. III. of 1856.*

*On some Additions to the Knowledge of the Cretaceous Rocks of India, by Thomas Oldham, LL. D., F. R. S., M. R. I. A., F. G. S. &c. Superintendent of the Geological Survey of India.*

At the meeting of the Society for the month of May 1857, Mr. Henry Blanford and myself were present, with the intention of laying before the Society, a brief notice of a very important discovery bearing on the Geology of India which had not long previously been made. This was the fact of the occurrence of rocks of the Cretaceous epoch in the western portion of the Nerbudda district. And the specimens illustrative of the intended communication were laid on the table. The attention of the meeting on that occasion, having been fully occupied by other matters of interest, and importance, which came before it, time did not allow of this geological communication being brought forward, and as both Mr. Blanford and myself shortly afterwards left Calcutta, the subject was not again brought before the Society. I am, however, desirous of recalling these facts, from the circumstance that the same discovery has subsequently been brought forward elsewhere, and I desire to place on record the facts of the case, more fully than has hitherto been done, that the friend whose zeal first led to the discovery may be rewarded by obtaining full merit for his intelligent research.

"All those who have given any attention to the study of Indian geology, are aware that previously to last year, rocks of the cretaceous epoch, were only known to occur, in the South

limits of which were supposed to be near Trichinopoly on the South, and near Pondicherry on the North. The true relations of this band of cretaceous rocks, have never been fully investigated, but a very beautifully preserved, and numerous suite of fossils had been collected from them by Messrs. Kaye and Brooke Cunliffe, of the Madras Civil Service, which were presented to the Geological Society of London. The description of these fossils was undertaken by the late Professor Edward Forbes, and a most valuable and instructive memoir, fully illustrated with excellent plates, was published in the 3rd part of the 7th vol. of the Geological Transactions of London.

After giving a detailed description of the species found, Professor Forbes entered on a discussion of the inferences to be drawn from the Fauna thus represented. It must be borne in mind that previously to this publication, the occurrence of any rocks, representatives of the cretaceous epoch in India, had often been denied, and that there was no fixed geological horizon to which such a new discovery could be referred. The physical relations of the rocks containing the fossils to any other recognised groups were unknown, and it was only from a discussion of the organic remains contained in them, that any just inference as to their geological age could be attained.

Professor Forbes entered fully into this discussion, and from a careful analysis of the evidence arrived at the conclusion, that all the beds from which fossils had been obtained were parts or members of one and the same series, and that that series was equivalent to the cretaceous series of Europe; the deposits at Trichinopoly and Verdachellum, being probably equivalent to the upper greensand and gault divisions of that series; the deposit near Pondicherry, being equivalent to the Neocomien, or lower greensand.

During a brief visit to Madras in the autumn of 1856, I was indebted to the kindness of Mr. Brooke Cunliffe, one of the original labourers at these deposits, for a valuable collection of these fossils chiefly from the Utatur locality. This collection at once proved the correctness of the closing words of Professor Forbes' valuable paper that "Verdachellum and Trichinopoly will doubtless yield many more species than have yet been brought to Europe," for in it were many beautiful and well marked forms previously undescribed. But it also showed conclusively, that a still further and more careful research was requisite, before it could be supposed that anything like fair data had been obtained, for arriving at trustworthy conclusions as to the true character of the Fauna of this period in Southern India. The relative abundance of species, and even of genera seemed in many respects very different from that which the original collection gave, and it appeared probable that much

of this difference in different localities was the result of a difference in depth in the sea at the time of deposit, and not of difference in time—a result not in accordance with the conclusions arrived at by Professor Forbes.

Among the small collection presented by Brooke Cunliffe, Esq., not less than 93 species were distinguished. Of this large number only 33 were known to Professor Forbes from the original collection; leaving an addition to the Fauna known up to that time from these rocks of 60 species. Without exception these 60 species all tended to confirm the opinion of Professor Forbes, that these rocks were of cretaceous age. A summary is given below of these additions generically, reserving the details of specific description until it is possible to prepare illustrations of the fossils. But a group or two may be referred to, in illustration of our remarks. Thus, taking the several well marked sections of the great genus *Ammonites*, among the large addition to the known catalogue of species, which Mr. Cunliffe's collection has given, we have none of the *Fimbriati*, an oolitic and cretaceous section; none of the *Flexuosi*, also a lower cretaceous section; none of the *Dentati*, also lower cretaceous; none of the *Armati*, an upper oolitic section; none of the *Lævigati*; while on the other hand, of the *Cristati*, a section essentially cretaceous, we find one; of the *Olypeiformi* also a cretaceous section, one: of the *Heterophylli* five, and all of the cretaceous subdivision of this section; of the *Ligati*, a group essentially cretaceous, not less than ten.

Of *Nautilus*, a genus having a larger development in the upper than in the lower beds of the cretaceous, we have three allied to other cretaceous forms; of *Belemnites*, confined to the upper portion of the cretaceous group, one. And other instances might be given. These will however suffice to shew, that a vast addition to the cretaceous Fauna of India still remains to be worked out.

I would add that Mr. H. F. Blanford, with others, is at present engaged in making out the relation of these rocks, and I confidently anticipate, that much light will be thrown upon the subject, by the careful examination of the Officers of the Geological Survey in that district.

**NERBUDDA DISTRICT.**—During the season of 1855-56, while engaged in the examination of the valley of the Nerbudda, I had the pleasure of meeting Captain R. H. Keatinge, Assistant Political Agent for Mewar, at Poonassa. Among other things our conversation turned upon the coralline limestone, of which the ancient town of Mandoo had been built. I took the opportunity of pointing out the extreme interest attaching to this limestone in a geological point of view, and the utter ignorance under which we rested as to its age or relations. It had been very ingeniously, and correctly inferred by Dr. Carter, in his carefully compiled "Summary of the Geology of India," that the limestone used at Mandoo had been derived from near Baug or Bagh, which inference I pointed out to Captain Keatinge in Dr. Carter's paper, telling him at the same time my own impression that it would

# GEOLOGY OF INDIA.

prove to be, not ~~oolitic~~, as provisionally supposed by Dr. Carter, but of the nummulitic age. Captain Keatinge says:

"Higher up at Surbaperee on the Maan, I thought I traced the following succession, (ascending) a light greenstone metamorphic or volcanic; a soft sandstone, very fine grained and white; compact limestone, bluish white; and then the coral limestone, the latter only containing corals. The compact fine limestone, is found at intervals all over the jungle, and has been very largely used for lime in the Mandoo days; the old kilns are without number. Now as to the fossils, I found them wherever an edge of stone lay over a convenient mud bed to retain them. The *Echinida Micraster coranguinum* (This is a mistake. It is a *Brissus*), were in great plenty (the Bheels call them Paunchia from their five marks) and what I suppose to be *Pecten 5-costatus*. (It is so). *Plagiostoma spinosum* and *Terebratula octoplicata* were numerous, the latter the most numerous and in best preservation, pieces of a large finely marked *Echinus* (*Cidaris*) and I have a half one of the same sort of which I send you a sketch. I have kept it to show the natives what I want on some future occasion. There is also a rude impression on a stone I have got, of a very large shell, say six inches long. *Inoceramus*?

On receipt of these fossils, they were at once looked to, and it was found that although some of these specific distinctions were not correct, they entirely supported the conclusions of Captain Keatinge; and that here to the West of Mhow and Indore, in a country where such was before altogether unknown, there existed extensive beds of the cretaceous series. The importance of this fact, in its bearing on all reasonings as to the physical geography of the country at former periods, will be obvious to every one who has considered such questions, and its influence on the question of the still doubtful age of the rocks in the adjoining district was also great. Eagerly therefore I congratulated Captain Keatinge on his valuable discovery, and urged a further exploration of the field. And I had the pleasure of hearing the result in the beginning of the year. (March 1857.) Captain Keatinge had, in company with Mr. Blackwell, Mineral viewer to the Bombay Government, revisited the Baug district in the month of January, and has favored me with an extract from his journal, which being brief, and full of interest, I give entire.

From these details it will be evident that to Captain Keatinge alone is due the merit of having first distinguished these fossils as cretaceous, and to him also belongs the merit of having most zealously and under considerable difficulties, collected a very tolerable series of them.

I shall not here discuss the conclusions arriv-

ed at by Dr. Carter in the notice referred to, in the Journal Bombay Asiatic Society, No. XX. July 1857, page 621, that these beds are truly neocomien, because I think we have not got any sufficient data to reason upon, I feel confident that the hasty reference of any group of rocks, to some acknowledged European *subdivision* based upon the occurrence of 3 or 4 ill-preserved and ill-identified fossils is both unphilosophical and injurious. The evidence here is abundantly good to say that these rocks represent the cretaceous era, but altogether insufficient to enable one to refer them to any subdivision of that great series.

Reserving, as before, the detailed specific description of these fossils, a generic summary is here given of the number, &c.

*Cephalopoda.*

Ammonites of the *Rhotomagensis* Section, 2

I had hoped to have procured during the past summer an extended series of fossils from this locality, and with a view of having it thorough-

ly examined, Mr. Wm. Theobald, Junr. was deputed to remain in that district, after his field work of last season had been concluded in the Nerbudda Valley. But the very disturbed state of all the country in that neighbourhood has rendered it impossible to carry out these views. Mr. Theobald, after considerable risk has escaped unhurt, but the examination of the Bagh country, must be deferred to a more favourable opportunity.

*On the age of the coal strata in Western Bengal and Central India.—By Rev. STEPHEN HISLOP, Nagpur.*

The age of the coal field of Newcastle, Australia, has been a subject of discussion to as great an extent almost as the geological position of our Indian carbonaceous strata. For my own part, I have been inclined to acquiesce in the view of McCoy, who, in the An. and Mag. of Nat. Hist. vol. XX., endeavours to prove that the beds with vegetable and those with animal remains belong to different formations,—that the former are Oolitic, while the latter must be referred to Palæozoic times. Not having his paper at present in my possession, I cannot now adduce the arguments by which he seeks to establish his opinion; but it is of little consequence, as the evidence, which I shall bring forward, in the sequel, on the age of our Indian coal measures, will be independent of the Palæozoic or Mesozoic character of those of N. S. Wales.

Perhaps the most interesting part, in a section of the rocks of Central India, is the junction of the thick bedded sandstone above with the laminated strata below. The latter, however various they may be in different localities as regards their lithologic and sometimes even their palæontologic features, may readily enough be distinguished by their relation to the superior beds, whose identity again is sufficiently attested by the iron bands, which run through their mass. This ferruginous sandstone is well developed at the Mahadeva Hills, in the north of the province of Nagpur, in the vicinity of the city itself, and at Kota on the Pranhita, in the dominions of the Nizam. The subjoined sections represent the succession of the strata at these places respectively, as far as they are known:

1.—Mahadeva Hills.

2.—Near Nagpore City.

3.—At Kota.

85 feet.	Massive sandstone with iron bands.	75 feet.	Massive sandstone with iron bands.	80 feet.	Massive sandstone with iron bands.
	Carbonaceous and other shales with ferns, vertebra, phyllothea, &c.		Laminated argillaceous sandstone with ferns, vertebra, phyllothea, &c.		Argillaceous limestone.
	Sandstone.		Sandstone.		Bituminous shales with fishes.
	Green shale.		Green shale.		Sandstone.
45 ft. 25 ft. 15 ft. 2,000 ft.		40 ft. 30 ft. 30 ft. 15 ft. 100 ft.	Red shale.	27 ft. 25 ft. 23 ft. 11 ft. 8 ft. 4 ft. 9 ft. 500 ft.	Bituminous shales with argillaceous limestone.
			Crystalline limestone.		Limestone.
					Clays with limestone.
					Red shale.
					Limestone.

In the preceding sections the dimensions depend partly on inference with the exception of those of No. 3, which were ascertained exactly by the measurement of the late Dr. T. L. Bell. They are, however, I believe, sufficiently accurate for the purpose for which they are given. That purpose is to exhibit the similarity, which exists among all these sections. Immediately under the upper sandstone, laminated rocks are seen in all. In section 1st, the shales are bituminous and carbonaceous, while in section 2nd, they are of argillaceous sand. But that they are of the same age, there can be no doubt, as many species of fossils are common to both. In comparing sections 1st and 3rd, we find that the latter instead of having the limestone all collected in the lower part of the section, as is the case at Nagpur and in many parts of the Nizam's country, has it interstratified with the shale; but leaving this peculiarity out of view, we perceive that in it the bituminous strata occupy the same position as in section 1st. The difference in organic remains between these two sections is more than counterbalanced by their agreement in the sequence of the inferior rocks, which (still omitting the interstratified argillaceous limestone from section 3rd, and choosing section 2nd as being better known for comparison with it, instead of section 1st) gives us in descending order sandstone and clay, red shale and limestone.

Now, if the fern-bearing coal shales and laminated sandstones of this province be the same as the fish-producing bituminous shales of Kota, then the light, which the last mentioned beds afford regarding their own age, may be cast back on the other two. It is satisfactory to find, that the evidence supplied by the Kota fossils is that of animal remains. The fishes that rewarded the researches of Drs. Walker and Bell have been pronounced by Sir P. Egerton to be true Oolitic forms, and probably of the age of the Lias; and therefore our vegetable organisms can be no older. To make this part of the evidence complete, and with the view of introducing some remarks on the testimony of our fossil plants, I may here mention, that between Nagpur and Chanda, at both of which places the upper sandstone has the usual iron bands, and the lower laminated beds the common vegetable remains, there is a district with Mangali as the centre (sixty miles S. of Nagpur) where the superior sandstone is less ferruginous, and the inferior or laminated beds are coloured by iron of a deep brick red. In the latter strata, where, from the analogy of the country both South and North of them, we should expect an abundance of ferns and stems, the remains of reptiles, fishes and entomostraca predominate, while the few vegetables that are found, are generally very different from those occurring in other parts of this territory. And yet from the position of this

sandstone I have very little doubt that it is the same as that of the more ordinary appearance. The teachings of its Fauna are interesting. The skull of a Labyrinthodont, named by Owen *Brachyops laticeps*, might suggest for it a Triassic or even Carboniferous age, but the plentifulness of scales of lepidotoid fishes forbids us to assign a more ancient epoch than the Jurassic; and the conclusion is unavoidable, not that our laminated sandstone is older than the age we have attributed to it, but that the Labyrinthodont family has come down to a more recent period than is generally believed.

But now it is time to inquire what we are to learn from our fossil plants, regarding the age of the carbonaceous shales and laminated sandstone of this province.

The testimony of vegetable remains I do not reckon of trifling value. When they belong to a large genus like *Pecopteris*, which has run through many successive changes of the earth's surface, then the information they supply is not very precise. But the very same may be said with greater force of the genus *Terebratula* in the Fossil Fauna. And I have observed that, even among plants of an undecided character as regards genus, there is generally some form, which distinguishes the species of one epoch from those of another. Besides, a geological age may be known from the abundance of a genus or family of plants at one period as compared with others. Though the discovery of a single species might not decide the question, yet if the genus, to which it belongs, culminates in a certain formation, and a particular stratum presents an unusually large proportion of that genus, then some idea may be formed of the age of that stratum. Such is the case with the entire fronded ferns. They reached their maximum development in the Jurassic period, as the Oolite of Scarborough, Stonesfield, and, according to H. Miller's recent researches, of the North of Scotland, plainly shows; and one of them, the genus *Tæniopteris*, which is so fitly associated in our carbonaceous strata with *Glossopteris* and *Cyclopteris*, is almost confined to the Oolite, there never having been an example of it hitherto met with in the true coal measures.

Having said thus much on the general principle, I proceed to apply it to special instances. There are three localities with which our strata admit of comparison—Stonesfield and Scarborough in England, and Richmond in Virginia U. S. The slate at the former British locality and the carbonaceous shales and sandstones at the latter, are universally acknowledged, I believe, to be Lower Oolitic; while the American coal formation referred to, is generally assigned to the same era. Now the connexion between our strata and the Stonesfield slate seems to be, the abundance of *Tæniopteris*, and a resemblance among the fruits or seeds. The similarity to

Scarborough consists in the presence of what Lindley and Hutton call *Equisetum laterale* with its deciduous discs at the joints of the stem, a plant, which to the best of my knowledge has hitherto been discovered nowhere else. The relation to Richmond is more intimate still. *Teniopteris magnifolia*, found there by Prof. W. B. Rogers, appears to be specifically identical with one of the same genus here; and the descriptions given of the Virginian *Calamites* erroneously so-called, correspond exactly with the *Phyllotheas* of Central India. And if we are to count the strata of Mangali among the representatives of our carbonaceous shales, then they furnish other two points of comparison with the Richmond coal basin, viz. in a *Kuorria*, and another stem, resembling a *Lepidodendron*, but which may be called an *Aphyllum* or perhaps *Aspidiaria*, I might here add a third link of connexion between those Mangali and Richmond beds, viz. the occurrence of two forms of *Eatomostraca* belonging to the genus *Estheria*. But in this instance, the evidence of the Fossil Fauna is not so distinct as that of the ancient Flora. The inference to be drawn from a particular species of *Teniopteris* being common to the rocks of Eastern Virginia and Central India is, in my opinion, conclusive as to their contemporaneousness; but not so that drawn from the discovery of *Estheria* in both, as the genus just named, after having been too frequently taken for a mollusc, is now recognised in the carboniferous formation, and, I believe, the old red sandstone, as well as in the Lias, the Oolite, and the Wealden. Judging from Sir C. Lyell's figure, there is a great agreement between his species and ours, but when Rupert Jones, one of our best authorities in this department, is able to pronounce upon them, his decision will set the matter at rest.

I suspect that a good many other instances of resemblance between our fossil plants and those of admitted jurassic strata might be pointed out; but materials as yet are deficient. There is still wanting a revision of our ancient flora, discriminating between true Carboniferous and Oolitic types. For example, how long have all furrowed stems in Europe and America, and I need not add India also, been referred to *Calamites* and more rarely *Equisetum*, whereas many of them, viz. those characterized by the absence of tubercles, and the opposite arrangement of their sulci, must undoubtedly be classed under the genus *Phyllothea*. To establish some such clear distinction as this, is a step towards the determination of the age of the rocks, in which those stems are respectively met with. While an alternate furrowed tuberculated stem is never found in the Oolite, on the other hand, the stems destitute of tubercles and with opposite sulcation almost exclusively occur in that formation.

Hitherto my remarks have been confined to the

carbonaceous strata and laminated sandstone of Central India. In now including the coal measures of Bengal in my comparison, I must bespeak indulgence, as I have personally examined none of the strata or fossils of that part of India, and must depend wholly on the descriptions and a few figures that have already been published.

By "coal measures of Bengal" of course I do not understand those on the N. or N. E. of Calcutta, some of which doubtless belong to a Tertiary age; but I mean those on the W. and N. W. of the Indian Metropolis, of which the strata in the Damuda basin may serve as a specimen.

These strata, I consider to be the same as what we have in the north of this province, and therefore, if my previous reasoning has been sound, they also are to be regarded as jurassic. The grounds of my identification are 1st, similarity in organic remains, and 2nd, in geological position.

1st. *Similarity of organic remains.*—In the bituminous shales of the Mahadevas we have the following Bengal fossil plants: *Tryzygia speciosa*, *Vertebraria indica*, and a species of *Phyllothea*, a fragment of which is figured by Dr. McClelland as *Poacites minor*. Geol. Surv. Tab. XVI. f. 4. In the carbonaceous shales of Umret, besides the *Phyllothea* now alluded to, another stem, but unfurrowed, which seems to resemble McClelland's *Poacites muricata*. Tab. XIV. f. 6. In the laminated sandstone of Kampti, in addition to *Vertebraria* and the two *Poacites* as above, *Teniopteris*, perhaps of the same species as at Rajmahal, and McClelland's *Pecopteris affinis*, Tab. XII. f. 11. b., which in our specimen, is seen to be a well marked species with a tripinnate frond.

In all these localities, the genus *Glossopteris* abounds, but it is so difficult to represent in a figure its minutely anastomosing venation, that nothing but a comparison of specimens side by side would warrant the identification of species. However, there is little fear of any of the Bengal ones failing to find a match among some of ours, as from the sandstone and coal shale, we must have about twelve species in all, many of them very perfect and in the height of fructification. While we seem to have outstripped North Eastern India in *Cyclopteris* and several other vegetable remains, we are decidedly behind in regard to the Cycadeæ. The only specimen, which I have procured is a small fragment from the sandstone of Kampti, the leaflets of which are narrower than the minutest blade of grass, that I have ever seen.

2nd. *Similarity of geological position.*—It may be supposed that, though there is a general agreement in fossils between the coal strata of Bengal and oolitic rocks here, yet their position may be slightly different. However, from all the descriptions of Bengal coal strata, to which I have had access, I have noticed that

## GOLD.

where the sandstone is present to afford materials for comparison, the tendency to bituminous and carbonaceous shales there, as here, occurs immediately under the great mass of arenaceous beds. In proof of this I need only refer to the sections given by Mr. Homfrey from Beng. As. Soc. Journ. Vol. XI. p. 748, Palamow and Singra, and to the observations made by Mr. Osborne on the supposed coal-field at Umlah ghat near Bidjeegurh. Ibid, Vol. VII. p. 843.

In conclusion I would add, that though amongst the Cutch oolitic strata some are evidently marine, yet from what I have seen of those in the Deccan or read of those in Bengal, I know of none of them in either of these districts that exhibit the least evidence of having been deposited in the sea or ocean: all seem to be of fresh-water origin.

(814) *GIRARDINIA LESCHENHAULTIANA*, the Neilgherry nettle, is frequent all over the higher range of the Neilgheries: the bark yields a fine, strong, white flax-like fibre, which the hill people obtain by plunging the plant in hot water, to deprive it of its virulently stinging properties, and then peeling the stalks. The textile material so prepared is of great strength, and the Todawars use it as thread.

(815) *GMEIINA ARBORA*. *CUMBULA*, *RHEED*.

Gumbhara, SANS. and BENG. | Gumar Goombar, HIND. Joogani Chukar, TEL.

Addimoduram, TAM. | Ussulussoos, ARAB.  
Meettie luckerie, DUK. | Beykhmechuck, PERS.  
Jethimadh, HIND. | *Ains. Mat. Med. p. 24.*

(817) *GOGA*. The name of a tree very generally found in most of the Philippines (*Encernada Philippensis*), the woody filaments of which yield a soapy matter much used in washing linen, and in the process of gold washing for the purpose of precipitating the metal from the sand. It is a shore or littoral plant, formerly ranked by botanists as an *Acacia*.—*Crawford's Dis. of the In. Islands, p. 144.*

(818) *GOLD* is found to occur in lumps in the alluvium of a mountain in Sarawak named Trian. Several of the lumps weighed from three to four bunkals, and they were rarely less than one are two amass in weight. Gold is found in Nanning, near the hill, Buket Jalatang.

In 1848 the total amount of gold in use in the world was estimated by the best authorities at about £600,000,000 sterling and the annual supply was believed to be between eight millions and nine millions sterling. From the recent extraordinary influx consequent on the opening of the gold fields of California and Australia we may compute the amount now (1858) in hand at

## GRANITE.

about £820,000,000 sterling. The data in the estimate are as follow:

From a table in Westgarth's Victoria, it appears that those two regions have produced,

California.	Australia.
1849 ... 2,000,000	None
1850 ... 9,000,000	None
1851 ... 13,000,000	1,000,000
1852 ... 15,000,000	14,000,000
1853 ... 20,000,000	20,000,000
or California an addition of..	£659,000,000
Australia do.....	35,000,000
All other sources in the five years..	40,000,000
To those add the present product of £50,000,000 per annum from all quarters for two years.....	100,000,000

£834,000,000

From this deduct for waste estimated at £2,000,000 per annum

for seven years ..... 14,000,000

£820,000,000

This net product now in the world is equivalent to about 205,000,000 ounces troy or 8542 tons. Great as the amount seems it could be all contained in a cubic block of gold only 23 feet in diameter. The gold coinage in Great Britain, France and the United States amounted in 1843 to £4,200,000 and in 1853, it was £41,800,000 or nearly ten-fold as large.—*H. D. R. page. 189.*

(819) *GOOMADEE*,

Goomadee, TEL. | Tagoomooda, TAM.

A large timber tree, a native of the mountainous parts of India.

The wood is used for a variety of economical purposes: that of such trees as will square into logs from eighteen to twenty-four inches resembles teak, the colour is almost exactly the same, the grain rather closer, at the same time it is as light or lighter and as easily worked. It is used for the decks of pinnaces about Chittagong, Dacca, &c, and is found to stand the weather without shrinking or warping better than any other wood known there.—*Rohde, M. S. S.*

(820) *GOOJUR*. A race in the villages in Northern India addicted to plunder.

(821) *GRANITE*. Many of the temples of Southern India are constructed of this stone. Its preservation, and the sharpness of its carvings, testify to its great durability and the absence of wear and decay makes it difficult to determine from appearances, the age of many oriental buildings made of this substance.

The best granite quarries are at Bangalore, Sadras, Cuddapah, Vizagapatam, and Bellary; and the different modes of quarrying by the action of fire, by wedges, or by gunpowder, and explained in "Captain Foord's valuable little practical treatise on building and road making."

The prices vary in different localities, according to the cost of labour and the hardness of

## GUANO.

the stone. There is a variety of greenstone resembling the whinstone of Scotland which is much used for building and ornamental purposes in Madras; it occurs in many parts of Southern India and is known under the names of freestone and grey granite. It is hard and durable but more expensive than the granites, from the greater labor of quarrying and cutting the blocks; at Madras the cost of this stone is as follows:

Tank stones, from 3 to 600 lbs. Rs. 1-4-0 per ton.

In addition to the general use of this material for building and religious sculptures, the natives occasionally make domestic articles of it, such as round millstones, pestles and mortars, door-posts, lintels, &c. Ornamental granites of bright colors occur in several localities, those of Salem, Chittoor and Seringapatam are flesh colored, red, green, yellow and grey. Those of Arcot and Goodoowanchair are pure white. The Bellary and Bangalore sienites, are red, grey, and white, with the colors blended in about equal proportions.

The two last may perhaps be considered the most durable in India, some of the pale-grey granites and pegmatites or binary granites of Southern India contain a large proportion of felspar which leads to their decay. The carvings at Conjeveram, Trichacoonum, Sadras and Chellumbrum, have lost a good deal of their sharpness from this cause, while those at Tarpur-tree, Wootimitta, Hera Toombal, and other places in the Ceded Districts are nearly as sharp as when first executed. In a few temples and Mahomedan tombs, the most richly cut pillars and ornaments are hewn out of basalt, augite, or basaltic hornblende. The best specimens of this kind of carving are at Vellore, Seerah, Timevelly, Humpee, Adony, Dummul, and Anagherry. The carvings have often a polished surface resembling black marble, but they are so hard as to strike fire with steel.—*M. E. J. R.*

(822) GRASSES. The pig, the cow, the horse, the sheep, and the goat, are the most useful creatures to men. They are wanted everywhere where men live, and there are seventy-two kinds of food which the pig will eat.

Two hundred and sixty-two, the horse.

Two hundred and eighty-seven, the sheep.

Four hundred and forty-nine, the goat.

(823) GUANO. Birds forming Guano, M. A. Ramonde, Professor of Natural History at Lima, was sent in 1853 by the Peruvian government to the Chincha Islands, in order to ascertain the quantity of guano existing in these Islands; during a sojourn of more than six weeks, he made observations on the origin of the guano deposit and on the birds to which it owes its existence. In some places the guano deposit is 30 metres in depth. From the bodies of animals as well as from various manufactured articles found in it, he

## GUINEA GRASS.

concludes that the deposit belongs to the present epoch of the earth's history. The birds observed during his visit were *Pelecanus majus*, Molin: *Carbo Gaimardii*, Lesson: *C. albigula*, Brandt: *Sula variegata*, Tschudi: *Spheniscus Humboldtii*, Meyen: *Plotus anhing*, Lin: *Rhyncops nigra*, Lem. *Larus modestus*, Tschudi: *Puffinaria Gannotii*, Lesson: *Sterna inca*, Lesson. These species do not all live constantly on the islands, some of them only appear at the breeding seasons. The pelicans do not appear to produce much guano as they almost always inhabit the cliffs and their excrement falls into the ocean. The same may be said of the species of *Carbo*. The species of *Sula* contribute more to the deposit, their number being greater and their habitations being more in the interior of the islands. The species of *Plotus* and *Rhyncops* are very rare, those of *Larus* are more numerous, the *Sternas* only visit the islands to lay their eggs, but their numbers are so very great that they must contribute in a great measure to the formation of guano. The *Spheniscus* abounds in the southern island which is inhabited. These birds not being able to fly hollow out habitations for themselves in the guano. The birds which produce largest quantity of guano are the *Puffinarias*: their number is incalculable. *L. Institut*, May 1856—*Ed. New. Phil. Jour. Nov.* 1856, page 178.

(825) GUILANDINA BONDUCELLA.  
NAT. ORD. CESALPINEÆ.

Bonduc nut, ENG. | Kutkaringa, ENG.

The nut is a common febrifuge in Bengal and other parts of India.—*Indian Annals*, No. 6.

(826) GUINEA GRASS, *Panicum Jumentorum* Spry's Suggest, p. 15. This grass has been cultivated to a considerable extent in India and Ceylon with more or less success according to the care and attention bestowed on it. When well manured and kept clear of weeds it grows more luxuriantly and admits of being cut every six weeks or two months. A small patch, near Colombo, which, beginning with above three quarters of an acre has gradually been extended to above an acre and a half, has now for seven or eight years, supplied 3 or 4 milch cows, and from 5 to 7 horses continually with all the grass required for their consumption and has latterly left a surplus which has been dried for bedding and hay. When first planted it frequently attains a height of even 9 feet and a stalk taken promiscuously from a small patch planted lately in Combaconum measured 10 feet  $4\frac{1}{2}$  in length, but when cut two or three times it grows thicker but not so high. It is exceedingly excellent feeding for horses and cattle, and is generally preferred by them to the ordinary country grass, though

## HEDYSARUM TUBEROSUM.

horses which are hard worked seem to prefer the dry grass roots supplied by the grass cutters. It should not be given to cattle fresh but the supply for one day should be cut the day previous, and it should not be cut too close to the ground, but the stalk ought to be left 7 to 9 inches high. It is a good plan to move the ground between the roots every time the grass is cut, and the ground should be heavily manured after every three or four cuttings. It is very hardy and may be easily propagated. It requires abundant moisture but will not live in a soil which is at all marshy. It answers best planted in small tufts 1 ft. 9 in. to 2 ft. apart, which rapidly spread into stools from 6 inch to 1 foot in diameter.—*Literis, M.S.S.*

(827) GURRAS. The Gurras is a Nepaul tree that affects the highest situations; its flowers are large and of a deep red; and yield by decoction a purplish colour, which are converted by acids into a tolerable pink.—*Smith's Nepaul*

(828) GURU OR GOOROO. Govind Sing was the last of the Padshahs. The ten Padshahs or Gurus were 1, Nanak; 2, Angad; 3, Amara-das; 4, Ramadas; 5, Arjun; 6, Hargovind; 7, Harkishan; 8, Teghbahadur; 9, Harah; 10, Govind Sing.

## II.

(831) HALHED, Nathaniel Brassy Halhed, in 1776 published a code of Gentoo laws or ordinations of the Pundits, from a Persian translation made from the original, written in the Sanscrit language.

(832) HANG TUAH. The celebrated champion Hang Tuah called "the Laksamana," must not be confounded with the Laksamana of the Portuguese writers, as the latter lived several generations after the first who accompanied King Mansur Shah to Majapahit.

(833) HAOU ? TSING ! TSING ! The Chinese salutation on meeting, meaning literally, are you well ? hail ! hail !

## (834) HEDYSARUM ALHAJI.

Camelsthorn, ENG.	Showk ul byza, ARAB.
Fève de loup, FR.	Badawert, Shiturkar,
Kamels dorn, Sussklec,	* PERS.
GR.	Juwa (n) sa, IND and
Dehveh Samani, TUR.	CASHMIR.

## (835) HEDYSARUM TUBEROSUM.

*Kadsumi.* Bank's Icon Kempf. tab. 25.

Darce, Goomodee, TEL.

Shrubby, twining; *leaflets*, downy *Racemes* long; *flowers* three-fold. *Legume* hairy, pendulous, four jointed; contracted at the joints.

A rare species, a native of the valleys far up

## HEIGHTS AND DISTANCES.

(829) GYPS. As Mr. Yurrell does not appear to discriminate the Gyps occidentalis, it is just possible that the bird which he notices appertains to that particular race, rather than to the genuine Gyps Fulvus of the Himalaya.

(830) GYPSUM. Sulphate of Lime or Gypsum is obtained in a good many districts. The best qualities are from Ootatoor near Trichinopoly, the Chingleput District, Sadras, Ennore, the Red Hills, Nellore, Masulipatam and Bangalore. The only new localities for this mineral are Sadras, the Red Hills, and Nellore. It is now known to occur very abundantly in the Madras Presidency in two forms, the Fibrous and Crystalline Gypsums, both free from Carbonate of Lime, and well suited for the Manufacture of Plaster of Paris, for moulds, busts, statues or ornaments. It occurs chiefly in the green sand or lower cretaceous formations, and is almost invariably accompanied by Fossils. The Fibrous Gypsum of Bangalore, Tiagur and Nellore, are the thickest and best. It is not yet known in what strata these occur, as the accompanying Fossils have not yet been traced, and the natives seem averse to show the localities for this mineral in those districts, though rewards of 20 Rupees have been offered for this information.—*M. E. J. R.*

amongst the mountains. It flowers during the hot season, at which time it is perfectly naked of leaves, being deciduous about the beginning of the cold season.

The root peeled and bruised into a cataplasm is employed by the natives of the mountains where it grows to reduce swellings of the joints.—*Roxb. Fl. Ind. Vol. III. page 863.*

## (836) HEDYCHUM SPICATUM.

Kapoor HIND.	Suttee, HIND.
Kuchree, HIND.	Sidhuol, HIND.
Scer, HIND.	

The root sticks are pounded with tobacco and used in the hookah.

## (837) HEIGHTS AND DISTANCES.

*Table of heights and distances along the proposed line of Railway from Surat to Agra. Communicated by Sir R. Hamilton, Bart., Agent to the Governor General for Central India. Bombay, Baroda and Central India Railway.*

Distance from Bombay in miles.	Name of place.	Height in feet above low water at Broach.
	Surat	80

## (838) HELICTERES ISORA:

Maror Phullee (Joukaphul) Patsum.

The fibre of the bark makes good ropes.

(839) HERITIERA, (*The Ka-na-zoo, or Saul, or Soondree-tree*) is a much larger tree than in Bengal, chiefly found on the tide waters. Fruit hangs in loose bunches, size of grapes, very pleasant, one seed. Leaves large, alternate, smooth, green on the upper side, and silvery white beneath. Timber, hard, straight-grained, elastic, and durable; used for millwork, spokes, shafts, oars, &c. There are several species of this valuable tree.—*Malcom's Travels in South Eastern Asia*, V. 1. p 282.

(840) HERODIAS. Three specimens observed of an Egret in winter dress seemed to differ only from ordinary *Herodias garzetta* in having black toes.

# HOOGLY RIVER.

## (841) HIBISCUS SERIACUS.

Ooda Godhul.

There are four varieties of this plant: two purple, a single and a double; and two white, a single and a double. The flowers are used to blacken the eyebrows and shoe leather.

(842) *HIRUNDO FLAVICOLLA*, BLYTH, belongs to the group of Republican Swallows, (*Petrochelidon* of the Prince of Canino), and has similar habits to the *H. fulva* of N. America. Upper parts glossy black with white lateral edges to the dorsal feathers more or less seen: the rump brownish and crown dark rufous; lower parts white, with black mesial streaks to the feathers of the throat and breast; the under surface of wings pale brown; tail slightly furcate, with a slight whitish spot more or less developed, towards the top of the inner web of most of the feathers: tertiaries also white tipped. Length about  $4\frac{1}{2}$  inches: of which tail  $1\frac{1}{4}$  inch, wing  $3\frac{1}{2}$ .

This interesting new retort nest-building swallow, writes Mr. Jerdon, I discovered during a late trip, and found it only in two spots, building in company, the nests crowded together on rocks overlying the rivers Soane and Karne in Bundelcund, at which time it was breeding.

(843) HIT. A miserable town, the usual place where caravans cross the Euphrates between Baghdad and Damascus. There are copious fountains of bitumen and Naphtha outside the town with the smell of which the whole water and air is infected. It is undoubtedly the place mentioned by Herodotus, under the name of "Is," as furnishing bitumen for the building of Babylon.

(844) HLA PET, *Burmese*, literally Wet-Tea, in Burmah, to the eastward of Bamo and Kountung, hills are visible, peopled by cateran Kakhyens, and by breeches wearing Paloungs, peaceably growing tea for pickling. This is the Hlapet under notice, which is made up with oil, salt, assafoetida, &c., into a sort of pickle, and is essential to the comfort of every Burman, being partaken of on all ceremonial occasions. It is floated to Ava on bamboo rafts, so as to be retained always partially wet.

## (845) HOOGLY RIVER.

*The mean Silt held in suspension, is as follows:—*

	Water. oz.	Solid earthy matter silt.	Carbonate of lime in water.	Total solid (silt and lime.)

(846) HONG, A word used in original Malayan invocations in the same way as the Arabic Bismillah is used in the modern ones. Hong is deemed a very unhallowed word, of great power, and so panas, (hot), that if any man uses a Hong invocation three times, nothing that he undertakes for himself will succeed, and he will live powerful but miserable, able to afflict or assist others, but unable to assist himself. It appears to be considered as a recognition of an essence or first principle beyond God and an appeal to it for power which God has not granted to man. It is used in Japanese invocations and a Javanese explains it to mean Embryo of Being, Primeval Essence; so that Sir T. Raffles' conjecture, that it is the Hindoo Om (Aum), is probably correct.—No. 5, Jour. Ind. Arch.

(847) HONEY. The honey of the Archipelago is a thin syrup, very inferior in flavour to that of temperate climates. It is chiefly sought on account of the wax, which forms a large article of exportation to Europe, India, and China.—Crawford's Des. Dic. of the Indian Islands, p. 152.

(848) HOPLOPTERUS VENTRALIS. Chœ-

tusia gregaria was mistaken in Mr. Jerdon's Catalogue of the birds of the peninsula of India for Hoplopterus ventralis.

(849) HORSE. EQUUS. Two Tibetan animals are enumerated as wild "*Equus Kiang*, Moorcroft; *E. hemione*" (quære *hemionus*?), "Auct? Found generally throughout Tibet.

"40. *Asinus equioides*, Bligh. Species want verification, spoken of by Moorcroft and others: called wild Ass by the Tibetans, and said to be common on the plains of Tibet. Mr. Hodson, gives a name to the latter animal, which Mr. Bligh is satisfied refers to *E. hemionus*, or the *Kiang* (vide XV, 146.)

The 28th No. of the *Calcutta Journal of Natural History* contains a paper by Mr. Hodson, entitled 'Description of the wild Ass and Wolf of Tibet,' in which he states—"There is, I believe, no species of wild Horse in Tibet, and only one species of wild Ass, viz., the Kiang:" and Moorcroft named this animal *Equus Kiang*, and Mr. Hodson had himself termed it *Asinus equioides*, but Mr. H. gave as a third name *Asinus polyodon*.

\* And below the point where the Damooda and Roopnarain join the Hooghly. The flood tide from the sea much augments the volume of water here so that the discharge shewn is that of the whole tidal water of the estuary rather than that of the river.

## INDIAN ARCHIPELAGO.

(850) HOT SPRING. There is a hot spring near Chirana Puteh, and another at Salanama in Rambau. Tin has been procured near Taba, and also near Chirana Puteh.

Dr. Watson, Jessore, submitted a memorandum on two hot springs in the village of Kujoorah.

Dr. Palmer, the Civil Surgeon of Jessore, reported on these Kujoorah Springs in December 1854, to the magistrate of the district.

(851) INAW-BEN, Burmese, is a large tree, of pale-yellow wood, preferred for making combs. It bears a large, fragrant fruit, but worthless.—*Crawford*, v. 1. p. 192.

(852) HUMULUS LUPULUS. The Hop, has been extensively distributed in the Himalayas. At 2,500, in the Deyrah Dhoon, it grows well: and at an altitude of 6,000 feet, in the Government gardens Missouri, but, in those regions, the best limit appears to be 4,000 or 4,500. A small sample grown in the Kangra valley was pronounced equal to the finest Kent hops.

(853) HUSSEIN, SHEIKH OF THE ALOUINS. —This individual was well known to all travellers who journeyed to Petra and Jerusalem by the way of Akaba, and generally to their cost. Taking advantage of their position, when they must either give up seeing Petra or accede to his exorbitant demands, he succeeded frequently in extorting a far larger sum than under ordinary circumstances would be paid for the hire of

## INDIAN ARCHIPELAGO.

camels. He was sly, wily and cunning, possessed of great skill in arranging a bargain, but no warrior; with his own tribe he bore the reputation of being a coward, though very clever with his tongue.

(854) HUSSUN AND HUSSEIN, sons of Ali and his wife Fatimah, the daughter of Mahomed, who were destroyed, the former by poison, and the latter slain by a party of Yezed's soldiery. Hussun was buried at Medina. They are regarded as martyrs, and during the Mohur-rum, "*Marsees*" or funeral odes are recited in their names, with pathos such as few can listen to without deep emotion.

### (855) HYDRILLA VERTICILLATA.

Kurelee, Hind.

This plant is used by the sugar refiners of Saharunpore for covering the surface of sugar, in order to allow the slow percolation of water when refining it.

(856) HYDROPHYLAX MARITIMA, Linn. Seaside *Hydrophylax*. A straggling herbaceous plant, native of the shores of Coromandel, where it shows its pale lilac blossoms great part of the year. The branches run over the sand, sometimes under the surface, and strike root at the joints. It answers well as a sand binding plant where the sand is moist.

(857) HYDROSAURUS SALVATOR, a reptile of India.

## I.

(858) IBI-GAMIN, a glacier in Eastern Thibet, in height 22,260 feet English = 20,886 French feet.

(859) INDIA. Among the plants of foreign growth introduced into India since its possession by the British, may be mentioned, the Tea plant, succeeding admirably in Assam, and the Himalayas, Coffee, Cinnamon, Nutmeg, Bread-Fruit, Mahogany, Log-wood, Alligator Pear, Cherimoyer, Litchee, Loquat, Arrowroot, Ammabolo; and among valuable vegetables, the potato, carrot, and turnip, and some English fruit trees. To these might be added a list of ornamental trees and shrubs, besides several indigenous plants, the cultivation of which has been greatly improved and increased.—*Indi. Anna. Medi. Scien.* p. 259.

(860) INDIAN ARCHIPELAGO. We will here give some information additional to that under the word Archipelago.

The term "Indian Archipelago" by which that group of islands is now generally known, cannot supply a concise and appropriate name for the native inhabitants. The Greek Archipelago is inhabited by Greeks, and they are

called so, but it would be very inappropriate to call a native of the Indian Archipelago Indians. It therefore becomes necessary to make use of the term "aboriginal tribes of the Indian Archipelago" or some equally long and inapplicable name, when speaking of the Malaya-Polynesians of the Archipelago, which from the constant repetition required in Ethnological discussion becomes almost offensive, so that a writer on this subject often experiences great difficulty in rendering his compositions even readable.

The French, who are distinguished by the extent of their writings on Ethnology, have adopted the terms Oceanie or Oceania and Malasia to designate the Indian Archipelago, neither of which, however, have been by any means generally adopted. The late Dr. Prichard, the distinguished author of the "Physical History of Mankind," uses the term Malasian when speaking of the brown-complexioned races of the Indian Archipelago, being the only English writer who appears to have noticed them. The reason is sufficiently obvious. The term "Oceania" is equally applicable to several other clusters of islands, and both that and "Malasia" are not

sufficiently suggestive to impress themselves on the memory of the general reader. Sir Stamford Raffles proposed that the brown complexioned races should be termed "Hither Polynesians" to distinguish them from the allied tribes of the Pacific who were to be termed "Further Polynesians;" but the Saxon adjunct seems to have met with no favour with ethnologists, for no other has adopted them.

Nevertheless the time has arrived when a distinctive name for the brown races of the Indian Archipelago is urgently required, and it should be made to accord as closely as possible with the terms by which that portion of the world is most generally known, namely "Indian Archipelago" or "Malayan Archipelago." By adopting the Greek word for "islands" as a terminal, for which we have a precedent in the term "Polynesia," the inhabitants of the "Indian Archipelago" or "Malayan Archipelago" would become respectively Indu-nesians or Malayu-nesians. One writer has chosen the latter for several reasons. The first term would be too general, and might be thought equally applicable to the Ceylonese and to the natives of the Maldives and Laccadives. The latter, on the other hand, will show on the face of it that it is intended to apply only to the brown races of the Archipelago, and it would be some acknowledgment of the enterprise of the Malaysians in having extended their voyages over the entire Archipelago previous to the arrival of Europeans. Their language, too, is spoken at every sea-port, with the exception of those of the Northern Philippines. —*Journal of the Indian Archipelago, February 1850, page 71.*

On the authority of Newbold, the population of the Malay Peninsula numbers as follows in several states.

Kedah contains, ... ..	50,000 inhabitants.
Pera, ... ..	35,000
Salangor, ... ..	12,000
Johore, ... ..	25,000 (a) Far too
Pahang, ... ..	40,000 high; and
Kemaman, ... ..	1,000 this we sus-
Trangganu, ... ..	30,000 pect is the
Kalantan, ... ..	50,000 case with
Patani (b) about, ... ..	30,000 many of the
Sungei Ujong, ... ..	3,200 inhabitants.
Rambau, ... ..	9,000
Johol, ... ..	2,000
Muar, ... ..	2,400
Orang Binua Johole, ... ..	1,000
*Orang Binua of the rest	} 25,000
of the Peninsula (c) ..	
Pinang and Province Wel-	} 120,000
lesly. <sup>1</sup> ... ..	
Malacca, <sup>1</sup> ... ..	46,882
Singapore, ... ..	60,000
Total.....	542,482

With regard to Patani, however we may men-

tion that previously to the Siamese invasion it contained 54,000 inhabitants, Newbold, vol. II. p. 70. I allow therefore 24,000 persons to have been slaughtered, or reduced to slavery on that occasion.

Judging solely from the number of the Orang Binua in Johole, the number there given is a very small computation, but although the length of the Peninsula is about 400 miles, by an average breadth of 120 miles, and we are aware generally that the interior of this vast space is inhabited by the various tribes of the Orang Binua and Samang, yet in the present state of our knowledge, it is better to state the population moderately as above.

Thus in the Straits Settlements, and the Malay Peninsula, we have a population moderately computed at something above half a million souls.—*Page 380.*

A close approximation of the Netherlands official documents, and the numbers given by Monsieur Temminck in vol. II p. 2, with the general account given by English writers, may convince us that the total amount of the population of Sumatra is about 4,550,000, and we may without further delay proceed to ascertain the number of inhabitants residing at the various islands in the vicinity as follows:—

Pulo Nias, <sup>1</sup> ... ..	250,000
Batoe group <sup>2</sup> ... ..	3,270
Poggy, Engano, &c. <sup>3</sup> ... ..	10,000
Linga, Bintang, Dryon, Singkip, Karimon,	
&c., &c. <sup>4</sup> ... ..	100,000
Banka <sup>5</sup> ... ..	40,000
Billiton... ..	7,000
Anambas group ... ..	3,500
Aor, Tingi, &c., &c. ... ..	1,000

Islands ... ..	Total...414,770
Sumatra... ..	4,550,000
Total of Sumatra and adjacent islands	4,964,770

—*Page 383.*

It will be easier to compute the third division of our task, which includes the island of Java with the small islands round it, besides Bali, Lombok, Sumbawa, &c.

The population of these islands may with a great degree of certainty be set down as follows:

Java and the small islands around.....	9,560,380 in 1845.
Increase in three years and a half.....*	500,300
Bah.....	900,000
Lombok.....	259,000
Sumbawa.....	200,000
Floris.....	278,000
Soler, Adenara, Lombatte, &c. &c. &c.,...	157,000
Sumba or Sandalwood island.....	425,000
Timort.....	669,000
Total of third division.....	12,909,680
Malayan Peninsula, &c.....	562,482
Sumatra &c.....	4,964,770
Total of three divisions.....	18,436,622

—*Jour. of the Indian Archipelago, Vol. III. No. IV. June 1849, page 384.*

## INDIAN ARCHIPELAGO.

St. Stamford Raffles states that of Palo Nias, at 230,000, but we have taken the authority of Mr. Oppe, who makes it from 250,000 to 300,000.

Temminck is the authority for that of the Bato group.

In the *Moniteur des Indes*, M. Temminck does not extend the population of the Poggy and Engano group as there are as yet no official returns on the subject.

On the authority of Temminck that of the Linga &c. group is given at 88,000 in 1840, but the islands being at peace, and no longer much exposed to the incursions of pirates we have allowed an increase of 12,000 in 9 years.

Temminck gives 85,000; increase allowed only 5,000 in 9 years, on account of climate and the description of labour.

This of Java in census of 1845 as given in the *Moniteur des Indes*, vol. II. p. 21 [see Dr. Bleeker's estimate and remarks vol. I of this journal p.p. 75, 76.—Ed.] This increase is calculated from *Moniteur des Indes* vol. II. p. 28. 1847 was given in this journal (vol. II p. 172) at 64,995. We did not recollect this in time to correct the text,—Ed.

Temminck vol. I. p. 340 gives the number in Bali at 800,000. Mons Van Den Breck in 1818, reckoned the population of this island at 987,500, which is reduced in the *Moniteur des Indes* to 738,000, by reckoning 4 persons to one fighting man, which is evidently a very low estimate. Allowing for a small increase, we have taken for Bali the medium of these authorities.

*Moniteur des Indes* Vol. II., p. 238, is the authority for the populations of Lombok.

*Moniteur des Indes*, Vol. I., p. 70, is the authority for that of Sumbawa if the table from which this number is extracted is certainly not exaggerated.

The languages of the islands facing the Malay Peninsula from Pegu to Sumatra, are Indonesian and not Ultra-Indian.

The languages spoken may be arranged in four groups, Peninsular, Sumatran, Javan, and Bornean.

*Achean*. This territory is so named by Europeans, from its principal port Ache. The Acheeny language is distinguished from all others in Asia by having the accent on the terminal instead of the penultimate syllable. In other respects its phonology has the prevailing Sumatran character.

*Andamani*, a language spoken in the Andaman islands. It is more purely Indonesian, being dissyllabic. In phonology, the Andamani is fundamentally opposed to Silongi, Nicobari and Simangi; Nias to Achean, and Tilanjani to the rude Malayan dialects which appear to have prevailed, and are partially preserved in the adjacent portion of Sumatra. The vocalic element is found in all the Sumatran and Peninsular languages; strong in Battan and Lampongi; less so

## INDIAN ARCHIPELAGO.

in the Malayan dialects, and comparatively weak in the Achean and Samangi. In the Andamani Telinjani and Nias, the consonantal element is very slight.

*Bali*, a language spoken in the Javan Archipelago.

*Battan*. In the Battan dialects of Sumatra, an Indonesian element predominates, and they have the closest affinity with Malay. The basis of Battan is similar to that of Nias, the latter language having spread into Sumatra, and modified the W. Indonesian character of Battan.

*Besisi*, a dialect of the Malayan peninsula.

*Binua*. The ruder Binua dialects of the Malayan Peninsula, when compared with Malay, present the same aspect as the uncultivated Sumatran. But having been, comparatively with the more civilized and powerful Battan and Achin races, almost completely subjected to Malayan influence, the indigenous peninsular vocabularies are rapidly disappearing. The languages of the *Binua* or *Sakai* of *Peru*, appears to resemble the ruder dialects of the Barman group, which is the next to the southward.

*Bornean languages*. Of these we may name the *Ngaju Kahayan* of the South coast, and that of the *Landaki* of the West coast, inland of Pontianak. Both are entirely Malay in their structure and formatives.

*Bugis*, a language spoken by the people of this name.

*Javan*. The Javan language participates to a certain extent in the peculiarities of the *Kawi*, and *e* is a frequent sound in both. Indeed, it would appear that most of the peculiarities of the Javan, or those phonetic traits which distinguish it from the general N. Indonesian phonology on the one side, and from E. Indonesian on the other, may be referred to the influence of *Kawi*. The other western languages of the Java group,—Sundan, Maduran, (with its dialect Bawean), and Bali, have phonologies in most respects similar to Javan, but preserving still more of the primitive W. Indonesian character. The Javan of the inhabitants of the Tenggu mountains is much more guttural than that of the polished Javans. Those of Sassak and Sanbawan are softer than Javan. Javan and Malayan have deeply influenced the languages of the trans-Javan chain. The principal distinction of the Javan group, is in the possession of a sacred or poetical and a deferential dialect, and the Hindu origin of the former. Remnants of deferential or sacred words are found in most of the languages of the Archipelago, as of the Malay, of Sumatra, and the peninsula, the Ngaju of Borneo, and the Wugi of Celebes. Their antiquity in Asia, is vouched for by Polynesian. Wherever Hinduism was established, it has left traces of a sacred or sacerdotal language. The phonology of the Javan group closely resembles that of the ruder Sumatran Peninsula.

and is chiefly distinguished from it by being more hollow, palatal, aspirate and distinct, and less nasal, guttural and smothered, while equally slow and broad. Sundan, however, amongst other striking affinities with the southern Sumatra-Peninsular Malay, has a decided nasal vowel. Javan is richer in formations than Malay, and it exhibits more freedom and power in their application. It participates to a certain extent in this peculiar consonantalism of the Kawi.

The other western languages of the Javan group, Sundan, Maduran (with its dialect Bawiru) and Bali, have phonologies in most respects similar to Javan, but preserving still more of the primitive N. Indonesian character. Those of Sassab and Sambawan are softer than Javan.

*Kayan.* This northern language must be considered as the most southerly of the N. E. projection of Borneo, a position which brings it into proximity with the Bissayan and E. Indonesian languages. This is assuming the correctness of Mr. Burn's statement that the Kayans have spread from the basin of the Tiding over the water shed into the north-western lands extending from the Bruni to the Rejang.

*Kawi.* The Kawi language preserves some evidence that, at the era of its formation, the Javan language was less removed from the adjacent languages than it afterwards became through the continued development and influence of Kawi, and a disposition to a factitious and pedantic culture.

*Lampongi,* a language spoken by the Lampongs.

*Landak,* a language spoken in the Archipelago.

*Maduran.* A language of the Archipelago, spoken in Madura.

*Malay.* The Malay language may have been preceded in Sumatra by languages more Philippine in their ideologies, and may have derived much from them, but it belongs fundamentally to a far lower development. The Malayan language, in its more ancient form, partook in a considerable measure, of the general character of the W. Indonesian of Sumatra, as is evident from the phonology of its ruder dialects. With the purer phonology of E. Indonesian, it combined the consonantal, aspirate, and guttural tendencies of the Malacca basin. Traces of this earlier character are still found in the centre of Malayan civilization, Menangkabau, where the language received its greatest culture, and attained the form, which, with some phonetic improvements and a few glossarial changes, it has preserved in its dissemination throughout the Archipelago. The Malay of Menangkabau is distinguished from all the other Sumatran languages, by its higher culture, purer phonology, wider prevalence and greater influence on other languages. It is superior to the ruder phonologies of the Peninsula and Sumatra, but also, to a large extent, Javan.

*Mantawai.* The language of a race who inhabit the Pera and Pagai groups. Its phonology, is considerably more Battan than that of Nias, purer than the ruder Malay, and apparently free from Sumatran aspirates.

*Ngjan,* a language of Borneo.

*Nias,* a language spoken in the Archipelago.

*Nicobari,* a language spoken in the Nicobar group.

The Nicobar language has a phonology, allied to that of the Silong and Samaug.

*Silongi,* a dissyllabic language spoken in the Mergui Archipelago.

*Simang.* The most northern of the old Indonesian languages of the Malay Peninsula, are those of the Simang tribes of Kidah and Pera. They are mainly dissyllabic, like other Asianic ones, but they have more monosyllables, and a dissyllabic tendency may still be detected in the contraction of some Malay words. The phonology of the Simang has some strong peculiarities, the voices low and soft compared with that of the Binua and Malay tribes.

*Sumatran.* The principal languages of Sumatra are the Battan dialects and the Malaya, these being spoken by the largest populations and over the widest extent of territory. In Sumatra we found at least three well marked languages, each occupying its own area, and a fourth still preserving its peculiar character and location, although much affected by foreign influence. In addition, the Western Islands contain at least three other distinct and stable languages. It has however only the diffusive language the Malay.

*Sundan* has some peculiarities which separate it from the other languages of the Javan group, and ally it to some of the W. Borneon and S. Peninsular dialects. Formatively Sundan is more simple than the Javan or even the Malayan, and approximates to the ruder Peninsular, Sumatran and Borneon languages.

*Tilanjani,* a language spoken in the Archipelago.

The use of letters has been immemorially known to all the more civilized nations of the Indian Archipelago, of the brown complexioned, lank haired race; and many alphabets, at once distinct from each other, and not borrowed from any foreign source, are to be found among them, from Sumatra to the west, to Celebes and the Philippines to the east.

The Javanese is certainly the most perfect alphabet of the Archipelago, and a brief account of it will give a general notion of the rest which, although they differ in form bear it, in principle, a common resemblance. It has a distinct, and invariable character for every sound in the language, and so far, therefore, it is a perfect system. The consonants amount to 19 and we represent them in roman letters, as follow: b. c. d. d. g. j. k. l. m. n. n. p. r. s. t. t. w. y. Besides

these there is the aspirate which always follows a vowel, and never aspirates a consonant. The vowels are 6 viz., a. a. e. i. o. u. The diphthongs are 2, viz ai. and au., but have no characters, being expressed only by their elements.

The Javanese alphabet, like all the others of the Archipelago, is written from left to right.

In the character thus described are written, the proper Javanese, the Sunda, the Bali, and occasionally I believe the Lombock. The Sunda, and Bali alphabets, however, want the palatals d. and t. Altogether, including Palembang in Sumatra, it is probable that the Javanese alphabet is current among no less a population than twelve millions.

In Sumatra, beginning from the west, the first evidence we have of a native written character is found among the Bataks, and it is singular enough that a nation of cannibals should possess the knowledge of letters.

The substantive characters of the Batak alphabet are the same as those of the Javanese, with the exception of the letter c and the palatals d and t which it wants.

The next alphabet we meet with, proceeding eastward, is the Korinchi, found in the country of the same name which borders on Menangkabau; the parent country of the Malay nation.

We come next to the Rejang, the alphabet of Lemba and Pasumah on the western side of Sumatra. This consists of 23 substantive characters.

The Lampong nation, which occupies that portion of the south-western side of Sumatra which lies opposite to Java, divided from it only by the Straits of Sunda, has its own peculiar alphabet, which consists of 19 substantive letters, the vowel a and the aspirate being included among them. The consonants correspond in power, exactly with the Javanese, the palatals d and t excepted, which the Lampong does not contain.

The Lampong, like the Rejang, has the Hindu classification, but it is not so correctly followed, the vowel a and the sibilant, are found out of place, and thrust in among the liquids.

After quitting Sumatra and Java proceeding eastward, the first example of a native alphabet we meet with occurs in Sumbawa, which is ascribed to the nation called Bina. This character is no longer in use, but has been long obsolete, having been superseded by the current alphabet of Celebes.

Celebes appears to have produced two distinct alphabets, the one at present in use over the whole island, and which has extended to Banton and Sumbawa, or wherever else indeed the Bugis nation has settled or colonized.

The modern Bugis alphabet consists of 23 substantive characters. All this shows that the Bugis alphabet is imperfect, and for fulness and precision not comparable to the Javanese. In form, the body of the Bugis character con-

sists for the most part of small segments of circles running horizontally, the letters being distinguished from each other, by small processes.

In fact, the main characteristic of the Malayan letters, their differing among themselves, and their differing equally from all foreign letters, leads to the inevitable conclusion, that each alphabet was a separate and independent invention, made, in all likelihood, in the localities in which we at present find them — *Page 775.*

What causes conduced to this early invention of letters among Malayan nations and at so many different and distant points, it is not very easy to say.

The nine alphabets of the Archipelago are the produce of five large islands only, out of the innumerable ones which compose it. The most fertile and civilized island, Java, has produced the most perfect alphabet, and that which has acquired the widest diffusion. The entire great group of the Philippines has produced, and that in its greatest and most fertile island only, a single alphabet; even this one is less perfect than the alphabets of the western nations, in proportion as the Philippine islanders, who first seen by Europeans, were in a lower state of civilization than the nations of the west of the Archipelago.

The Malayan Peninsula and Borneo, extensive as they are, have never given rise to an indigenous civilization, sufficient to raise their inhabitants beyond the condition of small and miserable communities, and hence no indigenous alphabet can be traced to them. Their more civilized inhabitants are invariably stranger emigrants. This must be owing to the absence of a certain kind of fertility, in the land available to the rude and feeble efforts of a native industry, such as elsewhere gave rise to a concentrated population, to leisure and to letters.

No kind of native writing can be traced to the Spice Islands which, notwithstanding their rich native productions, are incapable of yielding corn, iron, or cattle, the rough staples of early civilization, and without the presence of which, letters have never been invented or existed. In the great island of New Guinea, with its savage negro population, and with the same deficiencies, the presence of any kind of writing is not reasonably to be looked for.

No trace of a written character has been found in the wide extent of the Islands of the Pacific. Most of them are, probably, too small to have furnished a population, at once sufficiently numerous and concentrated, to generate the amount of civilization requisite for the purpose. In the great islands of New Zealand, with their comparatively energetic race of inhabitants, the discovery of letters would, most probably, have been made, as among some rude nations of Sumatra, had the civilization necessary not been precluded by the absence, as in the smaller islands, of the

larger animals for labour, and of all the cereal grasses for food.

The facility with which materials to write on are obtained in the countries occupied by the Malayan nations has, probably, contributed something towards the early discovery of the art of writing. The want of them, on the contrary, is known to have proved a great obstacle to the progress of letters, and probably was to their invention in temperate regions. The absence of a good material in ancient Europe hindered the invention of printing, and its presence in China, no doubt contributed largely to its early discovery in that country.

The Indian islanders write on palm leaves, which have received no other preparation than that of being dried, and cut in slips,—on the inner bark of trees, a little polished only by rubbing,—on slips of the bamboo cane, simply freed from its epidermis, and on stone, metal, and finally on paper.

The palm leaf employed is that of the lontar, or *borassus flabelliformis*. The Malay word is most likely a corruption of two words, *ron*, a leaf in Javanese, and *tal*, the proper name of this palm in Sanskrit. This seems corroborated by the Javanese name, which is written *rontal*. From the use of this word, it might, at first sight, be imagined that the practice of writing on palm leaves was derived from the Hindus. But it happens that this word, with many others wholly or partly Sanskrit, belongs to the ceremonial and factitious dialect of the Javanese language a genuine native name *kropyate*, existing for it, in the ordinary one, so that no safe conclusion can be drawn from this etymology.

The instrument for writing with on the palm leaf, bark, and the bamboo is an iron style, and their writing is, in fact, a rude engraving, which is rendered legible by rubbing powdered charcoal over the surface which falls into the grooves and is swept off the smooth surface.

The Javanese alone understand the manufacture of a kind of paper. This is evidently a native art, and not borrowed from strangers, as is plain from the material, the process, and the name. The plant, in the Javanese language, is called *gluga*, *Broussonetia papyrifera*, and the article itself *daluan* changed into *dalanian* for the polite language. The process is not the ingenious one of China, India, Persia and Europe, but greatly resembles that of making the Egyptian papyrus, and still more closely the preparation of the South-sea cloth, the raw material being, indeed, exactly the same. The true bark, cut in slips, is long macerated and beaten, and after being thus treated, slips of it are joined to each other over a smooth surface, and defects made good by patching. The fabric thus obtained is of a brownish grey colour, unequal in its texture, rigid, but strong.

With the exception of the Javanese, it does

not seem that the natives of the Archipelago ever wrote with ink, before they were instructed by the Arabs, no doubt from the absence of paper. The Javanese have a native name for "pen" and "ink," *sua* and *mansu*, but with the other nations, the only ones are Arabic, *kalam* and *dawat*, often indeed greatly disfigured, as in the example of the Bugis who convert them into *kalah* and *dawak*. The pen generally used is not reed as on the continent of Asia or a quill as in Europe, but a stub obtained from the *Aren palm*, *Saguernus saccharifera*.

Even paper is generally known to the Indian islanders by the Arabian name of *kartas*, so that it is probable that a true paper was imported long before the arrival of Europeans, although the natives were never taught the art of preparing it. At present European paper is in general use by all the more civilized nations, to the exclusion of Asiatic.—*Crawford on the Indian Archipelago, in Journal of the Indian Archipelago, Vol. II., No. XII., Decr. 1848, page 776-7-8.*

#### *Trading Ports of the Indian Archipelago.*

*Albay*, (Philippines.) The capital of a district of the same name, situated at the S. E. extremity of Luzon. The town, which contains many substantial buildings and about 13,000 inhabitants, lies two miles inland from the head of the Gulf of Albay, which is said to afford excellent anchorage, but is not well known, as the trade is carried on exclusively by pontoons and other coasting vessels, which carry the produce to Manila. Its position, near the St. Bernardino channel, which is much frequented by vessels from the Pacific bound to Manila, is important, but Sorsogon, an excellent harbour in the same district, presents so many superior advantages as a port of refuge for vessels that have met with accidents in the Pacific, and also as a trading port, that it will be preferred when the outports of the Philippines become the resort of European traders, an event which seems likely soon to take place. Albay is chiefly remarkable for producing Abaca or Manila hemp of better quality and in greater abundance than any other district in the Philippines. This production is obtained from the filaments of the *Musa textilis*, a sort of banana, which is easily propagated by transplanting the suckers that spring up about the roots of the old plants. The Abaca is generally planted in the cacao gardens, to shelter the shrubs from the heat of the sun, and it seems to be only in Albay, Leyte, and on the north coast of Mindanao that it is cultivated expressly as an article of commerce; the production of sugar absorbing the attention of planters in districts more adjacent to the capital. The filaments are detached from the stem by a very simple process, which closely resembles the mode of preparing hemp in Europe. The consumption of Manila hemp is daily increasing, more especially in the United States of America. As

it evidently requires a rich volcanic soil, it would probably succeed in the Moluccas and in the islands east of Java.

*Amboyna*, *Ambon* of the Malays and Dutch, the capital of the Netherlands possessions in the Moluccas, Lat. 3°41'41" S. Long. 128°9'51" E. Dumont d'Urville. The town and fort are situated on the S. E. side of a narrow inlet, 14 miles in depth, which penetrates the island in a N. E. direction and nearly divides it, the low isthmus which joins the two peninsulas being only a mile and a half across. The Bay of Amboyna, as this inlet is called, consists of an outer bay, on the shores of which the town is erected, and an inner bay or harbour, with low swampy shores, which admits and affords shelter to vessels of the largest size, but is very rarely resorted to, even by ships in want of repairs, owing to its extreme unhealthiness. The outer bay is unfathomable except in a few spots close to the shore. The anchorage is on a bank of coral and sand, which extends rather more than a quarter of a mile from the beach in front of the town, and is so steep that at a cable's length from the shore the depth is 25 fathoms. The best anchorage for a vessel having much cargo to discharge is about half a cable's length from the end of the government jetty, to which she can haul for the purpose of discharging, but this cannot be done without permission of the authorities, which is rarely withheld, however, unless there happen to be several ships of war in port, and it becomes necessary to keep the jetty clear for general purposes. The best anchorage for vessels coming for refreshments only, or whose stay is not likely to be long, lies to the N. E. of the jetty, and it will be necessary, especially during the S. E. monsoon, to carry a warp on shore to one of the anchors that are set up near the beach, to prevent the ship from being driven off the bank by the puffs of wind from the land. The bay is clear of hidden dangers, but when the weather is calm, the strength and eccentricity of the tides and eddies often cause alarm to strangers. The danger however is more apparent than real, as the currents never set home on the land. A ship entering the bay during the S. E. monsoon should pass pretty close round Nusa-Niva Point, and keep the starboard shore on board all the way up to the town; and if coming from the westward she should never attempt to enter the bay until she can lay up for this point and so be able to proceed along the weather shore. There is a bank with 15 to 25 fathoms upon it a few cables length to the S. of Nusa-Niva Point, which might prove useful to a ship driven out of the bay by the outset, an event which often takes place during the calms which prevail in the intervals of the westerly monsoon. The bottom is coral, so that only a kedge or stream anchor

should be used, as there might be difficulty in getting it again.

*Ley-timor*, the smaller peninsula on which the town is situated, is 15 miles long by 4 wide, and is traversed throughout its entire length by a range of hills, which rises abruptly from the sea on the S. E. side, but leaves several small plains on the shores of the bay, the largest of which is the site of the town of Amboyna. Kitu, the north-western peninsula, is entirely composed of hills, some of which attain considerable elevation, but scarcely sufficient to entitle them to the name of mountains. The nucleus of the town consists in Fort Victoria, which owes its origin to the Portuguese, but it has been much enlarged and improved by the Dutch. It contains the chief government office, the barracks for the troops, and the military store houses. The esplanade of the fort is surrounded by a number of large brick houses without an upper story, which, with those that line two streets running towards the Governor's house, at Batu Gadja, are occupied by the principal residents. The Campong China, which abuts on the S. side of the esplanade, is the commercial portion of the town, and is almost exclusively occupied by Chinese and other native merchants. It also contains the principal church, and a spacious market house, which is the greatest curiosity in Amboyna, not on account of its architecture, for that is of the most primitive oriental character, but from its being chiefly occupied during market hours, by the Orang Nigri, or people of the villages of the interior, who resort to it for the purpose of disposing of their surplus produce. To the north-east of the esplanade lies the "Burgher" quarter, which is occupied almost exclusively by the descendants of the old Portuguese and Dutch inhabitants, retired soldiers and their families, in fact by all those who in the persons of themselves or of their ancestors have been connected with Europeans. This quarter also contains a spacious church, in which the service of the Dutch Reformed religion is performed in the Malayan language.

*Population.* The island of Amboyna contains about 30,000 inhabitants, a fourth of whom occupy the capital and suburbs. The country people, who are called Orang Nigri, or villagers are the ancient inhabitants of the country. They are generally below the middle size, have neat and active figures, and that bright and intelligent look which is also characteristic of the Dyaks and of the people of the interior of Celebes, but is rarely met with among the Malayas or Javanese. The extreme neatness of their dress, which consists, generally of a sarong and kaboya of black calico, their great personal cleanliness, and their utter rejection of the use of siri or betlenut, which so disfigures the mouths and teeth of the Javanese and Malays, combines in producing a tout ensemble which excites no small degree

## INDIAN ARCHIPELAGO.

of surprise in European strangers from the western parts of the Archipelago, who probably learn for the first time how prepossessing a people the natives may become through education and cleanliness. Their ancient form of religion has almost entirely disappeared, its place being supplied by that of the Dutch Reformed Church. The villages are still, as formerly, under the local controul of the Orang Kaya or hereditary chiefs, who are assisted by several Orang Tua, or elders, and two or three Marino, or police officers. The Orang Kaya have also the local management of the clove plantations, and are responsible for the trees attached to their respective villages being kept in order, and for the entire annual supply of spice being sent in to government. Every village is provided with a native school-master or Guru, who has been educated at the institution of the Nederlandsch Zendeling Genootschap or Dutch Missionary Society, which has long been established at Amboyna. These school-masters teach reading and writing in the Malayan language, (the Roman character being employed) with the rudiments of arithmetic and geography, and as the entire juvenile male population with the greater portion of the female, attend the school, education is more generally diffused than in any country of Europe, with the exception, perhaps, of Holland and Scotland. The immense numbers of Malayan Bibles and other religious books that have been circulated, not only in Amboyna, but throughout the Moluccas, have produced an uniformity of idiom which greatly facilitates communication not only between Europeans and natives, but between the natives of the different islands themselves. Indeed the Malayan language here assumes a degree of importance which is unknown to the other European establishments in the Archipelago. It becomes in a great degree the language of general society, as Dutch is rarely spoken except by individuals born in Europe who are few in number. A constant correspondence is also kept up in Malayan between the Government and Orang Kaya of the interior. Under these favourable circumstances the Malayan dialect of the Moluccas affords a facility in expressing ideas which is unknown to the westward, where the language is only spoken generally by uneducated people, a circumstance which may eventually lead to the Amboyna dialect becoming the general medium of communication throughout the Archipelago. The Guru undertakes the duties of curates or lecturers, in addition to their own, performing divine service in the village churches, which, if far from the capital, are only occasionally visited by the European clergy; indeed the latter, owing to the smallness of their number, are called upon to perform the duties of bishops rather than of pastors. The villagers lead a very quiet life, subsisting chiefly on the produce of their lands,—sago, maize,

## INDIAN ARCHIPELAGO.

yams and the sugar of the tuak palm,—which is eked out with fish obtained chiefly by means of stone weirs erected on the coral reefs that line the coasts. Crime is almost unknown, indeed is rare even in the capital, where from the motley nature of the population, which includes many slaves from Macassar, Java, and Bali, it might be expected to prevail to some extent.

The natives of Amboyna have been characterised by strangers as excessively indolent and apathetic, which indeed might be looked for under the circumstances in which they are placed, but the accusation is most unjust. It is true that the Burghers who usually crowd the jetty, spending their time in angling for small fish, will refuse to carry even a light burthen; but it must be remembered that this branch of manual labour is the peculiar province of slaves, and it is not to be expected that the Vrij Burghers, poor enough as they usually are, but priding themselves in professing the same religion with the Europeans, would lower themselves by performing a description of labour which even Chinese and free Mahomedans would disdain. As to the natives of the interior, what with the labour of tending the clove trees, which must be performed, coupled with that of cultivating the soil, on which their very subsistence depends, they have very little idle time on their hands.

**Commercial History.** Amboyna had been resorted to by native traders from the west during many years previous to the first arrival of Europeans in the Archipelago, for the purpose of obtaining spices and other valuable articles produced on the island or collected from the neighbouring countries. In the year 1512, the Portuguese viceroy Albuquerque, after the conquest of Malacca, despatched two commanders Abreu and Serrano, to explore the Moluccas. They loaded cargoes of cloves at Guli-guli, a port on the south coast of Ceram, but on the return voyage of, the Seano, which had separated from her consort, was wrecked on Nuša Pinho, or Turtle Islands, to the south of Amboyna. Serrano and his crew, after undergoing many hardships, succeeded in making their escape from the island in a coracora or native prahu, which they got possession of by stratagem, the crew having landed for the purpose of plundering the shipwrecked people. In a few days Serrano reached Amboyna, where he was well received by the inhabitants, and it was probably owing to this accidental circumstance that Amboyna was selected as a trading station by the Portuguese, in preference to the neighbouring districts of Ceram, which produced spices in much greater abundance. In 1605, the Dutch under Vas der Hagen attacked Amboyna, when the Portuguese garrison surrendered and was allowed to depart in two prizes, one of which sailed to Manifa and the other to Solor. In 1611 the English, who had traded occasionally with the Moluccas,

established themselves at Luwu, a port on the peninsula of Huamowel, which forms the eastern extremity of Ceram, but they were soon expelled by the Dutch. In 1620, owing to remonstrances made in Europe, the English were allowed to establish a factory at Amboyna, but it existed only two years, when it was effectually annihilated by the celebrated massacre of 1622, to which individuals of both nations, even now, feel it painful to refer. Amboyna did not attain a very high degree of importance until the year 1652, when a treaty was entered into with the king of Ternate, in which he consented to the extermination of the spice trees throughout his dominions. The Dutch were now enabled to confine the culture of cloves to the island of Amboyna, and one or two others in the neighbourhood, and that of nutmegs to the Banda group, a system which is maintained until the present day. Hongi-togten, or expeditions for eradicating the spice trees of the neighbouring countries, were undertaken periodically by the Dutch governors assisted by the native princes in their interest, but this part of the system has now been discontinued. The English, on gaining possession of the Moluccas during the late war, maintained the system of monopoly and the Dutch government, since the restoration of the Moluccas, have very closely followed the footsteps of their old East India Company, but not with the same profitable results.

**Productions.** Amboyna is remarkable for the variety and importance of its vegetable productions. The island possesses a rich volcanic soil, and from the peculiarity of its position, it is accessible to the rains both of the Indian and Pacific Oceans, and as these prevail at different seasons of the year, the atmosphere is in an almost constant state of humidity, which proves highly favourable to vegetation. Its geographical position is also favourable with regard to variety of productions, for being situated in the close vicinity of New Guinea and Australia, it possesses the vegetation belonging to the Australian as well as to the Continental Indian system. The fruits, which all belong to the latter, are excellent in quality. They comprise the orange, lemon, shaddock, mangosteen, durian, mango, jambo, lansat, anona, guava, papaya, and tamarind. The bread fruit, (both the Manila and South Sea-island varieties,) is also found here. To these may be added the Kanari, a nut which furnishes a large quantity of oil, and which takes a conspicuous place in the domestic economy of the inhabitants. In its wild state, the nut although eaten abundantly by the inhabitants, is not very palatable to Europeans from the quantity of oil it contains, but the cultivated variety of the Kanari produces a fruit which is equal in flavour and delicacy to the almond, and is justly prized by all who have had opportunities of testing it. This tree belongs decidedly to the Aus-

tralian system, as it is not met with to the westward of Amboyna or perhaps, Buru, although it is common on the north coast of Australia, and, I believe, extends as far to the south as Moreton Bay, on the east coast. The Kanari-nut constitutes the principal food of the birds of Paradise, of Arru and New Guinea, during certain seasons of the year, and their intentness on seeking their food among the thick foliage of the trees affords opportunity to the hunters, who have previously concealed themselves among the branches, to shoot them with blunt arrows, when they fall to the ground and are secured by parties lying in wait below, and their bodies and feathers dried for exportation.

Of the numerous varieties of palm, the most useful are the sago, which usually grows in the swamps, and furnishes no small portion of the food of the inhabitants; the cocoanut, which is planted around every house; the sagoweer, nipa, and lontar, which furnish the tuak or toddy, a favourite drink of the natives, and the surplus of which is distilled by a simple process into an ardent spirit, or is boiled down into sugar. Lastly the pinang and nibong, the first of which furnishes the betel-nut of commerce, and the other supplies the inhabitants with a hard wood which is used for spears, bows, and digging-sticks or wooden spades for cultivating the earth. The stems of the sago palms when stripped of the leaves are used for fencing in the plantations, and are then called Gabba-gabba; while the leaves of the others are employed in making hats, mats, boxes, and baskets, of many varieties.

The aromatics, comprising the clove, nutmeg, kolit lawang, and kayu puteh or cajeput trees, all belong to the Australian system of vegetation, but it seems to have required the rich soil and moist climate of the Moluccas to bring the three first to perfection as articles of commerce. The kayu puteh, however which delights in the sandy soil of the sea shores, is found in greater perfection in Australia than in the Moluccas.

As the nutmeg and clove are both cultivated at Singapore, the former with great success, it will be unnecessary here to enter into minute particulars regarding the mode of cultivation, which, indeed, would be foreign to the expressed object of this memoir. The nutmeg of Amboyna is inferior to that of Singapore. It is only at the Banda Islands, which are especially devoted to the cultivation, that the nutmeg attains perfection, but there the clove tree yields a very different product, while at Amboyna it attains its highest state of development. As the climate of the two groups is precisely similar, this difference must be the result of a variety in the nature of the soil, in fact it soon becomes evident to those who have had opportunities of visiting both groups, that Banda and Amboyna

## INDIAN ARCHIPELAGO.

are by no means alike in this particular. It struck me that the soil of Banda was chiefly enriched by the ashes cast out from the Gunning Api, or volcano, which stands nearly in the centre of the group, while that of Amboyna seemed to owe its fertility to the presence of decomposed limestone. The climate of Singapore exactly corresponds with that of Amboyna and Banda; the soil, only, is different, but this the skill and perseverance of our nutmeg planters have counteracted by producing a soil, through the aid of manure, which closely corresponds with that of Banda. The want of success that has hitherto attended the planting of cloves may probably be owing to a similar system of manuring being adopted to that used in the nutmeg plantations, whereas a totally distinct system is evidently required to produce the clove-soil of Amboyna. Perhaps, it would be well to obtain a sample of this soil from Amboyna itself, when analysis would shew what ingredients were required to render the soil of Singapore similar to that of the former place. When this is effected, the cultivation of the clove in the Straits will, in all probability, be perfectly successful.

The animal kingdom presents the same mixture of Asiatic and Australian varieties which has been noticed as characterising the vegetable kingdom;—the Australian opossum co-existing with the porcupine and civet cat of the continent of Asia. A small variety of the kangaroo, which still exists on the Arru Islands, is said to have been found here also formerly, but it has now disappeared. The opossum is the only marsupial which seems to hold its ground in the presence of animals of the old world. It is found throughout Australia, New Guinea, and the Moluccas, and has become more numerous in the settled districts of New South Wales than when the continent was first settled. This is probably owing to their taking up their abode in the forest trees, whence they also derive their food, so that they are not liable to the attacks of beasts of prey. The monkey, the only animal of the old world likely to molest them, does not exist in a wild state at Amboyna, although it extends along the Sumatran and Trans-Javan chain as far as the east end of Timor. Deer abound in the forests, but these are known, to have been imported originally from Java and Macassar. The domestic quadrupeds, consisting of a few ponies, cattle, buffaloes, goats and hogs, have all been derived from the same sources, indeed the process of importation, as far as regards the two former, is still going on, the island not affording sufficient open pasturage for breeding purposes. Fish are abundant throughout the Moluccas, and the varieties are very numerous. Valentyn, who evidently turned great attention to this branch of natural history, delineates upwards of 500 varieties in the plates attached to his famous work on the Moluccas.

## INDIAN ARCHIPELAGO.

Agriculture has not made the slightest progress since the first arrival of Europeans. The plough is still unknown, or at all events, not used, the mode of turning up the ground by means of two sharp sticks, one held in each hand, being still generally practiced. The agricultural productions consist of maize, small-grained millet and pulse, with yams, sweet potatoes, melons and pumpkins. The sago palm can scarcely be said to be cultivated, as the young trees spring up spontaneously from the roots of those that have been cut down, so that the proprietor of a piece of sago ground has nothing to do but to thin the young trees, so as to afford room for those intended as standards to spread their branches. Rice, in sufficient quantities for the supply of the Government establishment and of those of the inhabitants who can afford to purchase it, is imported from Java. The cultivation is said to have been introduced, but in that case it must be confined within very narrow limits. The Count C. S. W. De Hogendorp, in his valuable "*Coup d'Œil sur l'Isle de Java*," (p. 321) states that the circumstance of the cultivation of rice never having become extended is attributed by some to the policy of the old Dutch E. I. Company, which threw every obstacle in the way of its cultivation, with the view of keeping the natives in greater subjection from their being only able to obtain supplies through the medium of the Company; while others attribute it to the indolence and inactivity of the natives. A third cause exists in the country people being obliged to reside on the uplands, for the purpose of attending to the clove plantations; they therefore live remote from the low country which alone is adapted for rice planting. Indeed they could not have formed rice-saws, without first destroying the sago palms with which the low lands are covered, an act which would have been exceedingly unwise under the circumstances of the case, as the sago could be collected at any season of the year, in fact, whenever the clove plantations did not require their attendance; while the rice cultivation would entail continued labour during long periods and they had no guarantee that the produce would not be appropriated by their rulers, as the spices were already. The natives of Amboyna, if left to themselves, would probably never have become a rice growing people, but their rich products would have enabled them to purchase abundance from the inhabitants of the western islands. This would have given rise to a commerce which has never existed under the grasping monopoly of Europeans, although it was maintained to a great extent previous to their arrival in the East. Probably the greatest evil that the natives of the Moluccas have derived from contact with civilized nations, consists in their having been deprived, for more than three centuries, of the nutritious food that is necessary to the full development of human powers.

The cacao, or chocolate-bean has lately been introduced, and grows luxuriantly on several spots in the neighbourhood of the capital. The like success has attended coffee and indigo, indeed Amboyna seems to be well suited to any tropical production that requires a rich soil and a moist climate.

Commerce. The Nederlandsch. Handel Maatschappij, or Netherlands Trading Company, has an establishment here, which, with the Government, engrosses almost the entire foreign commerce. Amboyna, although the capital of the Moluccas, does not possess a single merchant ship; but some of the Chinese and other natives have a few trading prahus which are chiefly employed in bringing provisions from the neighbouring coasts of Ceram and Buru. The annual supplies of rice and other stores for the Government, and of goods for the Maatschappij establishment, are brought from Java during the westerly monsoon in ships belonging to Arab or other native merchants settled in Java, and these return in May, June, and July, with the yearly produce of cloves, and such articles as the Maatschappij agent may have collected. The latter, however, receives payment for his piece-goods and other European manufactures chiefly in silver guilders or rupees, which are circulated to a considerable extent here owing to the government officers, the troops, and the crews of ships of war on the station, being paid their salaries or wages upon the spot. The annual supply of cloves, averages about 300,000 pounds. The receipts on account of this spice amounted in the year 1822, to upwards of 500,000 guilders, while the expenses of the cultivation, or rather, of the small rewards given to the Orang Kaya, Orang Tua, and Maruinos, who superintended the plantations, amounted to 90,000 guilders. During this year the supply was rather less than usual, but it is never, even with the duties and taxes levied at the port, sufficient to pay the expenses of the establishment, which amount to the sum of nearly 1,000,000 guilders annually. Vessels belonging to other European nations than their own are not allowed to trade at Amboyna, and even private vessels of the Dutch very rarely visit the port unless taken up for government service. These restrictions are sometimes evaded by small Spanish vessels from the Philippines which bring cargoes of Manila segars and China goods, and take cacas and cash in return. This subject was discussed at some length in the Singapore newspapers about 12 months ago, as it was thought that from the provisions of our treaty with the Netherlands of 1824 it would afford an opening for British vessels also. The 7th Article of this treaty runs thus: "The Molucca Islands and especially Amboyna, Banda, Ternate and their immediate dependencies are excepted from the operation of the 1st, 2nd, 3rd and 4th Articles until the Netherlands Govern-

ment shall think fit to abandon the monopoly of spices: but if the said government shall at any time previous to such abandonment of the monopoly allow the subjects of any power other than a native Asiatic power to carry on any commercial intercourse with the said islands the subjects of his Britannic majesty shall be admitted to such intercourse upon a footing precisely similar."

More importance was given to this concession (if it may be so called) on the part of the Dutch, in thus admitting Spanish vessels to participate in the commerce of the Moluccas, than it really deserved, for if the British government had deemed the opening of the ports of the Moluccas as conducive to our commercial interests it might have been effected years ago, and without any reference to the provisions of the treaty. I find that I have stated the fact of Spanish vessels being admitted to trade at the port of Amboyna in a report which was sent home to government soon after my visit to Amboyna in 1841, and which was published in the Parliamentary papers relating to port Essington in 1843. As I understand the fact has been denied by parties in Holland, I insert an extract from a recent work on the Philippines by M. Mallat, which was published in Paris in 1846, and as he cannot be supposed to have been aware of the full bearing of his paragraph, he may be considered, at least, as a disinterested authority.

"The departure of the vessels for the Moluccas takes place during the months of December and January. The merchandise they carry is of a similar description to that exported to Sulu, to which may be added fancy articles, and gown pieces for the ladies of the residents and the superior authorities. Their return cargoes consist of cacao, birds of paradise, cloves, nutmegs, &c. These islands are Dutch possessions; commerce can therefore be carried on there in the greatest security. But the import duties being very considerable, a great deal of contraband trade is carried on. The freight is 5 per cent. on the value of the merchandize, and  $\frac{3}{4}$  per cent. additional per month."—*Les Philippines: Histoire, Géographie, Mœurs, Agriculture, Industrie, et Commerce des Colonies Espagnoles dans L'Océanie par J. Mallat. Paris 1846, vol. II. page 326.*

These vessels, however, take the precaution of touching at the island of Sulu, and obtaining a native flag and papers. The local authorities seem to be pretty well aware of the evasion, but they are heartily ashamed of the illiberality of their Government, and are evidently not inclined to make very minute inquiries when the parties do not attempt to break the regulations of the port. English and American vessels in distress occasionally put in at Amboyna, where they are treated with hospitality, and allowed to purchase such stores and refreshments as the place affords.

but a guard of soldiers is put on board the ship the moment she arrives, and remains there until the period of her departure, which proves so annoying that the port is never resorted to except in cases of the utmost necessity.

The following articles are to be obtained at Amboyna in addition to those already mentioned:—Ambergris, kayu puteh oil, bees-wax, ebony lingoa-wood, kayu-buka, and many other ornamental woods, some of which are prepared in slabs from 6 to 9 feet in diameter. When the resources of the neighbouring countries come to be developed, this list will be greatly increased, especially in the particular of resins and dye woods, of which the adjacent island of Ceram furnishes many varieties.

The present miserable state of commerce at Amboyna scarcely authorises so long a notice as the above, but it is not likely to remain a sealed port for ever, and when once opened, it must become the emporium of the Moluccas and New Guinea. Much as we may admire the moral courage of the Dutch in persisting to maintain a system that has been repudiated by every other civilized nation, it may be doubted whether their line of policy, which is so well calculated to invite aggression, will tend much to the stability of their Indian empire. As long as the system of monopoly had only to encounter the apathy of European nations, which naturally do not care much about the commerce of remote places concerning which they know little, affairs have progressed smoothly enough, but a new nation is springing up in the south, and gradually spreading over the continent of Australia, which is already beginning to shew symptoms of discontent at being excluded either actually by the absolute prohibition, as in the Moluccas, or virtually by exacting regulations, as in Java, from ports in their immediate neighbourhood, whence they could derive those supplies to tropical produce for which they are now obliged to resort to the more distant Spanish settlements of the Philippines. That there is a strong and intelligent party in Holland favourable to liberal measures is well known, and I cannot conclude this article more appropriately than by extracting the following remarks from the valuable work quoted above, the author of which has spent the greater portion of his life in the public service of the Dutch Indian settlements, and I believe, now fills the important office of vice president of the Council of Batavia.

It is a fact unfortunately too well known, and which it will answer no good purpose to pass over in silence, that the Company, to insure the monopoly of its own wares, caused all the clove and nutmeg trees, beyond the number necessary to produce the quantity of spices that they could sell, to be rooted up and destroyed, often with arms in their hands. To effect so general a devastation it became necessary to commit

many violences, to maintain costly garrisons, to build forts and strongholds, to pay pensions to the native chiefs, and in fine to deprive themselves of every other source of revenue.

“Again if the results of this system ensured them the exclusive trade in spices, still they were never able to sell more, in ordinary years, than two millions of guilders worth of cloves, nutmegs and mace, while to obtain them they often expended more than three millions, all in ruining these beautiful countries from which they might have derived immense advantages under a good administration.

“The cruel effects of this fatal system on the countries and nations that had the misfortune to be subject to its influence will be long felt, but let us hasten to say that a salutary balm has been shed upon the bleeding wounds, and we may now lay the first foundations on which an edifice may be erected more consonant with present times and existing manners.” The author here alludes to the results of the Governor General’s visit to the Moluccas in 1824, when the oppressive laws of the former Dutch East India Company, which were supposed to have led to the risings and massacres of Sapama and Nusa Laut in 1817-18 were greatly modified. These reforms, however, were not full enough to satisfy the natives, for in 1829 a conspiracy, in which many of the chiefs and a portion of the garrison were concerned, having for its object the massacre of the Europeans, was discovered, by accident when on the eve of consummation. Six of the ringleaders were shot, among whom was Raja Wangi, a chief of great influence with the natives. Lieut. Bastiaanse, who was an eye witness to the execution, states that Raja Wangi was not struck by a single ball at the first discharge, which tended to confirm a belief on the part of the natives that he was invulnerable.—*Voyages dans Les Molugues*. Paris, 1845. p. 103.

“No point in the colonial system has probably excited more attention on the part of the superior authorities in our Indian possessions than the problem as to the advantage or disadvantage of the monopoly of spices in the Moluccas; or has called forth more opposite opinions.

“The partisans of the olden time, and such are not wanting, pretend that without the monopoly of spices the Moluccas will not be of the slightest value to the state. The partisans of liberal ideas assert, on their part, that this exclusive monopoly carries a destructive germ that will in the long run cause the total loss of these valuable possessions. Nevertheless all parties agree that to carry out with success, and without imminent danger, changes in the existing system, it will be necessary to act slowly and with prudence, following a plan that will only present at first preparatory courses, and the effects of which will only make themselves felt in proportion to the results obtained.” Neau

moins tous etaient d'accord que, pour faire avec succes et sans un danger imminent des changemens dans le systeme existant, il fallait agir avec prudence et lentement, d'apres un plan que ne presenterait d'abord que des voies preparatoires, et dont les effets ne se feraient ressentir qu'au fur et a mesure des resultats obtenus. Coup d'œil sur l'isle de Java et les autres possessions Neerlandaises dans L' Archipel des Indes, par le Comte C. S. W. de Hogendorp, 1830, p.p. 315 et seq.

Similar opinions to those expressed by the intelligent author quoted above have been long entertained by the great bulk of the educated classes in Holland. Respecting the annual loss sustained by the government in supporting the monopoly there can be no doubt, and its oppressive bearing on the native population is sufficiently indicated by the annual decrease in their numbers. The Baron Melville Vancarnbee, in his valuable statistics of the population of the Moluccas (*Moniteur des Indes* for 1847-48) gives the following as the amount of population of Amboyna and its environs during the years 1837 to 1841 inclusive. 1837—11,702; 1838—10,909, 1839—9,041, 1840—9,274; 1841—8,966.

(861) *Amfuang* (Timor.) A small trading port about 40 miles to the north of Coepang, which is occasionally resorted to by prahus and small vessels for the purpose of obtaining sandal-wood and bees-wax, but for some years past the greater portion of the produce has been carried overland to Coepang, owing to the coasting trade having been much interrupted by Lanun pirates, who now visit the eastern islands of the Archipelago more frequently than formerly from their having been much disturbed lately on the coasts of Java, Borneo and Sumatra, by Dutch and English vessels of war. Amfuang was also frequently resorted to by British and American whaling vessels, chiefly to obtain spars for masts and booms, which are abundant and of good quality in the neighbourhood of the anchorage. In May, 1843, the English Whaler "Sarah Elizabeth," Captain Bellinghurst, while at Amfuang, with two officers and 14 men on shore cutting spars, was attacked by 5 large and several smaller Lanun prahus, the crews of which, after killing, taking or dispersing the party employed on shore, boarded the ship, the Captain and the remainder of the crew, who were taken by surprise, escaping to sea in the whale-boats. The pirates, after plundering the ship, burnt her to the water's edge, in which state she was found by three other whalers, that had been met with by Captain Bellinghurst in the offing, and had accompanied him for the purpose of rescuing his ship from the pirates. A full account of this transaction will be found in the "*Moniteur des Indes*" for 1847-48, p.p. 34-5. The article alluded to is the production of the late Jankpeer

Comets de Groot, who was during several years Resident of the neighbouring settlement of Rhio, and afterwards Secretary General to the Colonial department of Holland. For particulars respecting the productions, &c. see Coepang.

In many of the English charts, the next bay to the north of Coepang is called Amfuang Bay, but it is not known by that name to the natives, who apply it only to a spot a few miles to the N.E. of the Gunners Coin, in lat. 9° 3' 58" S. long. 123° 41' 24" Freycinet, and to an inland territory of which the latter is, or was, the sea-port.

(862) *Amhai or Amahoy* (Ceram.) A port on the south side of the island, nearly due north from Nusa Laut, the easternmost of the Amboyna group. The town lies on the shores of a small bay a short distance within Point Koba, which forms the eastern extreme of a large bight called Elipa-puteh. This place was formerly much frequented by native traders from the west, as the anchorage is said to be excellent, and easy of access, while the neighbouring territory once was remarkable for the abundance and quality of the clove produce. The trees, however, were destroyed when the power of the Dutch became paramount in these parts, and its trade has since consisted exclusively in a pretty constant intercourse, kept up by means of boats or cora-coras, with Amboyna, which place it supplies with large quantities, of provisions and pottery. The inhabitants are nearly Christians, and as the country around is populous and productive, it may at some future time become a trading port of consequence. The bay, although supposed to be clear of hidden danger, should be approached with caution, as the fringing reefs extend in some places more than a mile from the shore.

(863) *Amomang Bay* (Celebes.) A deep, narrow inlet on the north coast of Celebes, about 30 miles to the westward of Menado, the capital of the Dutch possessions in the northeast part of the island. This bay is much more secure than that of Menado, which is exposed to the heavy squalls from the northwest. Its north eastern shore should be avoided, as it is lined by an extensive coral reef. The best anchorage is in the southwest part of the bay, where vessels lie in 40 fathoms very near the shore, but sheltered from all winds. There is a small, but well constructed fort, in which the civil commandant resides, who is under the orders of the Resident of Menado. The chief production of Amomang is black coir or gummati rope, which is of excellent quality. A considerable quantity of coffee is grown in the neighbourhood, but this is all transported to Menado for shipment to Europe in the vessels of the Netherlands Trading Company. Amomang offers no inducement to the visits of trading vessels, but it abounds in refreshments, a circumstance of which the English and Ameri-

## INDIAN ARCHIPELAGO.

can whalers formerly availed themselves, but latterly certain restrictions have been placed on the intercourse between the inhabitants and foreign vessels, which will probably prevent its being resorted to in future. In February, last year, the American whaling ship *Octavia* anchored in Amomang Bay, but the commandant refused to allow the crew to purchase supplies until permission had been obtained from the Resident of Menado. In the course of two days the necessary permission arrived, accompanied by an order that the ship should depart from the Bay within twenty-four hours. It is said that the opening of Menado to foreign vessels, which occurred a short time ago, was accompanied by an order on the part of the Batavian government excluding them from all the coffee ports on the north coast of Celebes. Such a daring assumption of power is scarcely credible, but it seems, nevertheless, to be true.

(364) *Ampanam*, (Lombok,) a town on the west side of the island, in lat 8° 33' S. Horsburgh. It has of late years become the chief resort of foreign traders, owing to its being the nearest seaport town to Mataram, the present residence of the king of Lombok, which is distant inland about 3 miles. The anchorage is due west of the town in 10 to 15 fathoms sand, from 1 to 2 miles off shore, the latter distance being generally chosen from November to March, when the westerly monsoon sometimes blows with great strength, throwing a short but turbulent sea into the roads. During the easterly monsoon, ships taking in cargoes of rice often lie much closer to the shore, which is nearly steep to, it being necessary to use the utmost despatch in embarking their cargoes while the sea is smooth, for, although the wind is off the land during this season, a tremendous surf is often experienced for days together, which cuts off all communication with the shore except by signal, while its strength lasts. This surf is caused by heavy rollers from the S. W. which occur at intervals, and generally during calm weather. A similar phenomenon is experienced at the island of Ascension and sometimes at St. Helena. It is probably caused by submarine volcanic action, as it is evidently unconnected with atmospheric causes. In all the old charts a sort of ridge or bar, with 7 fathoms water upon it, is laid down, and is distinctly mentioned in Horsburgh's Directory as having existed in 1811, but this has certainly disappeared. A small knoll, having less than 3 fathoms upon it, lies to the south of the anchorage, about three miles off shore, which seems to be identical with the "shoalest part of the ledge" in the directions by Mr. Dawson, an officer of H. M. S. *Psyche*. (Horsburgh's Directory, vol. ii. p. 657, Edition of 1843. In October 1841, we anchored about a mile and a half to the N. E. of this knoll in H. M. S. *Britomart*, and immediately abreast of the town.

## INDIAN ARCHIPELAGO.

Ampanam was not frequented by European vessels previous to the year 1834; Labu-Hadji and Pijou, in the eastern side of the island, being then the chief resort of ships requiring cargoes of rice for the China market. About this period an English merchant, Mr. King, who had previously carried on business at Batavia, established himself at Ampanam under the protection of the King of Mataram, and was afterwards followed by Messrs. Bird and Lange, two Danish gentlemen connected with the China trade. The facilities their presence afforded for carrying on a commercial intercourse with the inhabitants, soon attracted British vessels that had taken out emigrants to Australia, and were on their way to the Indian ports to obtain return cargoes for Europe. These would often obtain a freight to China, the Mauritius, Singapore, and sometimes to England, or, if the captain was possessed of Treasury or other Bills could procure rice on the owner's account which would materially aid in paying the ships expenses if taken to China. During the year ending in October 1841 no less than 25 English ships loaded at Ampanam, either on owner's account, or on that of Mr King, who had now become the sole European merchant, Messrs. Bird and Lange, having removed to the neighbouring island of Bali, where the latter soon acquired great influence over the natives, and was of material assistance to the Dutch during their late invasion of Bali. In the meantime, Mr King, who had assisted the king of Mataram in an internal war which had made him master of the entire island, was appointed Bandar or controller of the trade of Ampanam, which virtually gave him the monopoly of trade as far as regarded Europeans. This prosperity, however, did not last many years, for a few months after our visit in the *Britomart*, a commissioner of the Dutch Government arrived from Batavia. The manuscript of his report, as well as that of Mr Moliere, an agent of the Handel Maatschappij, who visited Bali and Lombok in 1839, were used by Mr. Melville in the compilation of his valuable account of these islands, having been placed at his disposal by the ministry of the Colonies. (*Moniteur des Indes*, 1846-47.) Mr. King has since removed to Koti, on the coast of Borneo, and the British trade with Lombok may be said to have ceased entirely. Even the national flag of Lombok, which was often to be seen formerly in the roads of Singapore, has disappeared for some time past. It is scarcely known where the immense rice produce of the island now goes to, but it is said to be carried for the most part to Java in Dutch and native vessels, where it is much required to make up the deficiency caused by a large portion of the rice lands of Java being now devoted to the culture of produce better suited to the European market.

Ampanam also exports coffee, cotton, and to-

bacco. Refreshments of all kinds suited to the wants of shipping, -bullocks, pigs, poultry, yams, and sweet potatoes, -are to be obtained in great abundance; which causes the port to become a favourite resort for American Whalers during the season in which they fish in the seas contiguous to the N. W. Coast of Australia, namely May to September, when the boisterous season of the southern hemisphere obliges them to resort for a time to low latitudes. Labu Hadji, on the opposite coast of the island, has now, however, become the chief refreshment port of Lombok, the king having made a request that the whalers would confine their visits to the villages of the east coast, where refreshments were more abundant, and where the crews could enjoy themselves on shore without interfering with the trade. No less than 17 whalers have been seen in the port of Ampanan at one time, each with a crew of upwards of 30 men. Traders visiting Ampanan, or any of the ports East of Java, should take every precaution to prevent surprise, as the Lanun pirates now resort to these parts in greater numbers than formerly their course along the north-west coast of Borneo to the coasts of Sumatra and the Malay Peninsula being now obstructed by the settlement of Labuan, which they cannot pass without some intelligence being received of their motions, and this being conveyed speedily to Singapore, would inevitably lead to their being sought out and destroyed. In the year 1837 the schooner Maria Frederica, Captain Gregory, was cut off in Ampanan roads; and in 1840, the English whaler Mary, Captain Blossie, while at anchor at the North Islands, near the N. W. point of Lombok, was surprised and taken by a fleet of Lanun prahus; See "Moniteur des Indes" for 1847-48 p.p. 17 and 21; but the vessel and crew were soon afterwards ransomed for a large sum in Spanish dollars by Mr. King, who subsequently finding that the pirates still remained there, fitted out an English merchant brig, that was then loading rice for England, with guns and men supplied by the king of Lombok, and succeeded in driving them away for a time. There are no port dues, or charges, unless such may have been introduced recently.

For particulars concerning the population, productions, commerce, manufactures, &c., see Lombok. For the sake of arrangement I find it necessary sometimes thus to refer the reader to articles which have not yet appeared. Where an island or district contains several ports as is the case with Lombok, it would create needless repetition were I to give full particulars on the points mentioned in the text under the heading of each port. I have therefore classed all those minor ports which admit such arrangement into small geographical districts, such as "Sulu Archipelago," "Sumatra (West Coast)," "Timor" &c. a plan which may appear to leave the articles

unfinished, but will be found to facilitate reference when the publication is completed.—*Journal of the Indian Archipelago, Vol. IV., No. VII., July 1850, page from 380 to 410.*

(865) INDIGOFERA GLANDULOSA. Willd. III. 1227.

Barugadam, Tel. \*

A small shrubby species, a native of moist rich lands amongst the mountains. Flowers and ripens its seeds during the wet and cold seasons.

Of the seeds the natives of the hilly countries make meal, which they bake into bread, and use as an article of diet; when more agreeable food is scarce. Cattle are fond of the plant.—*Roxburgh's Flora Indica, vol. III, p. 378.*

(866) IND-WAY. Burmese. This large tree abounds in the Burmese forests. Seed the size of a small egg. It yields a very useful resinous gum, of a light-grey colour, used in the seams of boats, &c. It is obtained not only by incision, but drops on the ground, and is gathered without trouble. It is very much used, and may always be bought in the bazaar.—*Malcolm. v. 1, p. 192.*

(867) INDRO. See MACASSAR.

(868) IN-JEEN. Burmese. This is a large tree, common in the upper provinces. Flowers, small, pinkish yellow, very fragrant, growing in clusters, and celebrated in Burman poetry. This is said to be the species of wood generally found petrified near the earth-oil wells on the Irrawaddy. Gaudama died near one of these trees.—*Malcolm. v. 1, p. 192.*

(869) INK. The Tamools occasionally make ink with nearly the same materials, that we do; but that which is used by native writers in the Cutcheries and public offices is prepared by the following very different process.

First. A burnt rice water is to be made in this way. Half a seer of rice, burnt black, is to be well boiled in a seer and a half of water, till but one seer remains, then strain off the dregs. To this seer of burnt rice water, is to be added two pollams of *Kumburruk* (Lac) boil them well together and strain off the dregs.

Half a seer of *Carpoo veruum* (Lamp black) and half a pollam of *Vullam pisin* (Gum Arabic) are then to be well rubbed into a fine powder, and generally added to the decoction of *Kumburruk*, and burnt rice water; when the whole are to be rubbed together, and well shaken at different intervals, for the space of three days.

The Mahomedans prepare their ink which they call *seahie* in the following manner:

Take of Lamp black and Gum Arabic equal quantities, and pound them together into a very fine powder. This powder is then to be moistened with the juice of the pulp of the *Kuttalay*, (small aloe), and well rubbed at intervals, for two days together, after which it is to be formed into little cakes, that are to be put on plantain leaves, and dried in the sun for use.

(870) IPPU. The name of a tree in Borneo

## IRON.

from which is obtained the famous Borneon poison, with which the Idan tribe poison their darts. The poison is collected by this tribe only, and its effects are similar to those of the Llana and Ticinma of South America.—*Dalrymple's account of Sulu.*

(871) IRON. A considerable quantity is produced in the Salem district, and two varieties are obtained, one remarkable for its softness and malleability, the other for its steel-like hardness, which adapts it for the formation of edge-tools, cold chisels, &c.

The following are names given to this metal in process of adaptation to its finished manufacture. Culties or blooms of iron. Palms or bars of iron. Vuttoms or pieces of cast steel as it comes from the clay crucibles. Oolies or bars drawn out from the clay crucibles. Iron beads which ooze out from the blooms in the blast furnace.

Bloom iron from Paulghaut is readily malleable and furnishes a hard steel-like iron. The natives state that it is necessary to subject the bloom to a second fusion and much hammering before they can bring it to the state of the soft malleable iron, in which it is met with as an article of commerce.

This statement seems to correspond with what one might expect from the difference of appearance of two samples; the one of Paulghaut, being highly metallic as shown by its bright metallic lustre, while the black charry look of the other seems to indicate such an excess of oxids as to unfit it for the hammer.

At the Madras Exhibition of 1857, one of the richest departments of the Exhibition was the ores of iron and steel. "Almost every district in the Presidency contributes specimens, and the collections from some localities are very extensive and varied; those from Cuddapah, Hyderabad, Bellary and Coimbatore are particularly deserving of notice. Large collections were also sent by Capt. Puckle and Mr. Addis from Bangalore, but the quality of the ores is not rich at that station. The principal ores of the Cuddapah district are red, brown, and purple in colour, which yield iron of excellent quality and very malleable. Some of the magnetic iron ores of the same district are particularly rich in iron, and a few of them contain traces of manganese those from Chemoor and Poolevendalah, the latter is magnetic although earthy and dull red in the fracture and bright red in the streak. The steel grey and granular iron ores from Chitwail, Camalapoor, and Gooruncondah are all rich in the metal and more or less magnetic. The yellow ochre and rusty ores of the Muddenpully Talook are said to yield good malleable iron. The steel grey iron sand of Comarole and Yendapully in the Doopaud Talook are highly magnetic and contain a little manganese.

## IRON.

The micaceous iron ore and iron glance of the Doopaud Talook are also rich in the metal.

The most prevalent iron ores of the Hyderabad territories seem to be the rusty brown, red and yellow ochres; the iron or steel sands with manganese, and the specular or glance ores: now of the latter however are magnetic. The black, brown, and red cellular iron ores are abundant in this collection, and a great deal of attention appears to have been bestowed on the minerals of this District and on the iron ores in particular.

The Bellary District yields a variety of iron ores, some of which are very rich in the metal and several of them associate with manganese. The prevailing ores of iron, of this district are the black and grey ores alternating with sandstone liver colored ores (which has been repeatedly sent to Madras as copper ore) and red jaspery clay iron stones. They are also associated in the same district and in the vicinity of Kurnool and Gooty with Magnesian Limestone, Grits, conglomerates, Aluminous shale. Fire Clay and Black Dolomite, but the Fossils which are the surest indications have still to be sought for.

The Iron Ores sent by the Coimbatore Local Committee were of very fine quality, being particularly rich in the metal and the most highly magnetic in the Exhibition.

A Sub-Committee of the Jury carefully examined all the ores of Iron with the blow pipe, and as to their magnetic properties, and the following was the result of these examinations.

Magnetic Iron Glance of fine quality occurs in Coimbatore, Salem, Cuddapah and Vellore.

Magnetic Hæmatites in Cuddapah.

Magnetic Iron sand also in Cuddapah; none of the Iron sands of other districts magnetic.

Magnetic rusty Ochrey Iron Ore from Hyderabad was as the other Ores of Hyderabad magnetic or magnetic Iron Ores from Bellary, Masulipatam, Bangalore, Mysore, or other districts. Manganese detected in the Iron Ores of Hyderabad, Kurnool, Bellary, the Bababooden Hills, Mysore and Vizianagrum.

Meteoric Iron, exhibited from Mysore and Pondicherry.

Micaceous Iron Ores of good quality from Cuddapah and Vizianagrum. Brown hæmatite and Reddle from the Red Hills, Bellary and Hyderabad. Common Iron Pyrites or Soornamooky stone is exhibited in Magnesian Limestone from Kurnool, Cuddapah and Gooty. Radiated Pyrites in large pieces in black marble from Nundial and near Cuddapah. This is an important substance, and if procurable in large quantities, it might be used for the manufacture of sulphur, sulphuric acid, yellow and red ochres or polishing powder.

Iron Pyrites was also exhibited in small quantities in Aluminous shale from near Bangalore; where it is found in large quantities in this matrix, or if the alum slate be of a dark olive

green with the sulphuret of Iron diffused through it, Alum may be prepared from it.

(872) **IVORY.** A writer, in Blackwood's Magazine, (March 1853), on Zanzibar and the East Coast of Africa, says that tusks weighing 100lbs. each are common; those of 175lbs are not rare, and he had heard of a pair whose joint weight was 560 lbs.

(873) **IVORY VEGETABLE. VEGETABLE IVORY PLANT.** Vegetable ivory is now imported chiefly from the river Magdalena into Europe and the United States of America: in some years no less than 150 tons of it were imported into England. The nuts may be purchased in the toy shops of the British metropolis for a few pence each but when bought in large quantities they are obtained at a much cheaper rate. In August 1854, 1000 nuts were sold in London for seven shillings and six pence. The ivory plant is confined to the continent of South America where it grows between the 9th degree of north and the 8th degree of south latitude, and the 70th and 79th of west longitude. It inhabits damp localities such as confined valleys, banks of rivers and rivulets and is found not only on the lower coast region as in Darien but also on mountains at an elevation of more than 3000 feet above the sea as in Ocaña. Amongst the Spaniards and their descendants it is known by the name of *Palme de marfil* (ivory palm), whilst its fruit is called by them *Cabeza de negro*, (negro's head) and its seed *marfil vegetal* (vegetable ivory.) The Indians on the banks of the Magdalena term the plant *Tagua*; those on the coast of Darien, *Anta*; and those of Peru, *Pullipunta* and *Homera*. It is generally found in separate groves seldom intermixed with other trees or shrubs and where herbs are rarely met with the ground appearing as if it had been swept. The trunk is always pulled down partly by its own weight, partly by its aerial roots and thus forms a creeping caudex which is frequently twenty feet long but is seldom higher than six feet. The top is crowned with from twelve to twenty pinnatisect leaves, the entire length of which is from eighteen to twenty feet. The fruit, a collection of from six to seven drupes, forms clusters which are as large as a man's head and stand at first erect, but when approaching maturity its weight increasing and the leaf stalk which had up to that period supported the bulky mass having rotted away, it hangs down. A

plant bears at one time from six to eight of these heads each weighing when ripe about twenty-five pounds. The drupes are covered outside with hard woody protuberances formed in the same manner as those of the trunk of *Testudinaria elephantipes*. Each drupe contains from six to nine seeds but generally seven. The testa is thick, bony, the embryo peripheral, and placed near the hilum. Habit is nearly the only link which connects *Phytelephas* with the order of Palms, its simple spadix, its imperfect flowers, its indefinite number of stamens and its embryo situated in the axis of a fleshy albumen separate it from Palms and proclaim it (in conjunction with other characters which it presents) a member of Endlicher's class *spadicifloræ* and Lindley's alliance, *Arales*. Botanists enumerate four orders as belonging to that great division (*Pistiaceæ*, *Pandaneæ*, *Typhaceæ* and *Aroideæ*. To *Pistiaceæ* and *Pandaneæ* it cannot belong, because it has an exile placentation. Amongst *Typhaceæ* it cannot be placed, because it has a multiovular ovary: with *Aroideæ* it cannot be associated because it has a drupaceous fruit. Repelled by these and other considerations from placing it with any of the natural orders above mentioned and finding it impossible to trace out any relationship of it with any other group than the *spadicifloræ* we are compelled to adopt the views of Martius who looks upon it as the type of a new natural order (*Phyttelephanthææ*). The uses of the ivory plant may, as far as they are known, be summed up in a few words. The Indians cover their cottage with the leaves of it but only when those of palms are not procurable as the latter lasts much longer than the former. The seed at first contains a clear insipid fluid with which travellers allay their thirst; afterwards, this same liquor becomes milky and sweet and it changes its taste by degrees as it acquires solidity until at last it is almost as hard as ivory. The liquor contained in the young fruits turns acid if they are cut from the tree and kept sometime. From the kernels (albumen) the American Indians, as well as European turners fashion the knobs of walking sticks the reels of spindles and little toys which are whiter than animal ivory and equally hard if they are not put under water, and if they are they become white and hard when dried again. Bears, hogs and turkeys devour the young fruit with avidity—*Seeman* in *Botanical Magazine*, May 1856, page 192.\*

## J.

(874) **JAHEZ**, *Arab.* or **MAYNDHEE** *Hind.* a Mahomedan bride's bridal paraphernalia, which is carried in procession to the bridegroom's house.

(875) **JAINS.** The Jains are a sect of Buddhists,\* pread all over India, and many of their doctrines and ceremonies resemble those of the Brahmins, but the Jain, though he burns the

dead, does not make offerings to them, when the rite, called *Shraddhu*, is performed; for he says, "of what use is it to pour oil into the lamp, after the wick is burnt to ashes." The Hindoos believe that the soul of the dead must remain in purgatory for a certain time, that the performance of *Shraddhu* releases it after a given period, and

## JATROPHA CURCAS.

that by means of gifts to the Brahmin priests, the manes of the deceased is translated to heaven. Shraddhu means literally, firm faith, and is a ceremony that reminds one of the Roman Catholic masses for the repose of the soul of the dead. The Jains bear a very strong resemblance to the Buddhists in their religious doctrines; they believe that there is a God, but affirm that he can be known only by such as become absorbed in his essence; that therefore, a person knowing God, ceases to possess identity; that hence, it is absurd for a human being to pretend to know him. The moment you discover him, your identity ceases. They deny that God was ever incarnated, and, like the Buddhists, believe that men, by their virtuous conduct, became omniscient, and may thus be considered infallible. They hold, that since the beginning of time, only twenty-four such superior beings have appeared for the reformation of mankind; these they style the 'Tivithankar.' Their priests, the Jatis not only never put anything to death, but never eat anything that has had life. The Jains resemble the Hindoos, in having caste, which the Buddhists have not, in the Mysore and the south of India, the Jains admit also certain of the Hindoo deities into the courts of their temples, which is never done, either in Bombay, the Mahratta country, Guzerat, or Marwara, in all of which places there are numbers of Jains."

The Jains are easily recognized by their lofty turbans, and by the sectarian mark on their foreheads—a straight line of sandal-wood powder, drawn from the roots of the hair to the junction of the nose with the forehead. When they pray they cover their mouths with a cloth, lest they should swallow any insect, and gently brush the place where they intend to sit lest they should crush one. When they find a stray bird, or animal, they take the greatest care of it. Ward, in his work on the literature and mythology of the Hindoos, says, that the Jains carry this principle so far, that "they cannot allow that any crime justifies the taking away of life; hence like the Buddhists, they consider kings, as the administrators of justice, the greatest of sinners."—*Chow Chow*, p. 12 to 15.

(876) JAMBAN, the name of a tree in Canara. It grows from two to four feet in diameter and from twenty-five to forty feet in height. This wood, as also the kulbagi, is very scarce. It very much resembles mahogany and is generally used for house furniture.—*Edye, M. and C.*

## (877) JATROPHA CURCAS.

Physic nut, ENG.  
Pignon d'inde, FR.  
Brechnuss schwarze, GER.  
Dund berrie, ARAB.  
Coat amunaka, TAM.  
Pahari Arund, also Bagbarinda, HIND.

Bugla barendee, PERS.  
Rotenjot (paharee) INDIAN and CASHMERE.  
Nagalam, TEL.  
Kanana herundum, SANS.  
Adevie Amida, TEL.

This is one of the most common small trees

## JOHORE ARCHIPELAGO.

or bushes on the coast of Coromandel, and is in flower and fruit all the year.—*Roxburgh's Flora Indica*, Vol III. p. 687.

### The Seed.

The seeds of this species of Jatropha, are called in Tamil *Coat amanaka mootloo*, they are purgative, but very uncertain in their operation; proving sometimes violent like those of the *Ner-valum*, though they are naturally milder. Before administering them, they should be cleared from the thin filament in which they are closely enveloped; after which two or three may be taken as a dose. The leaves which are five angled, are considered as discutient, and the milky juice of the plant is supposed to have a detergent and healing quality.

### The nut.

The nut is called in Dukhanie *Junglie erundie ke beenge* and in Arabic *Dundebirrie*.

### The oil.

A fixed oil, (called in Canarese *Mara hara'n unay*) is prepared from the seeds of the *Coat amunaka*, which is reckoned a valuable external application in cases of Itch and Herpes; it is also used in chronic Rheumatism, and for the domestic purpose of burning in lamps.—*Ainslie's Materia Medica*, v. I, p. 73.

The milky juice boiled with oxide of iron, makes a fine black varnish.

(878) JATROPIA PANDURÆFOLIA. The juice is used by the natives to remove specks from the cornea.

(879) JAVA AND MADURA, two islands occupied by the Dutch in the Eastern Archipelago, for their civil Government are divided into 22 provinces or prefectures, known under the names of Residencies. The census of 1845, showed a population in Java of 9,542,045.—*No. 3, Jour. Ind. Arch.*

(880) JHILUM. The district of Jhilum as at present constituted, extends from the Jhilum river on the E. to the Attock on the W. On the north it is bounded by the various talukas of Rawalpindi as the public country, Potwar, Syud Kusran and Nurali, the river Suan and Pindi Gheb; on the south, its limit is the Jhilum river as far as Dhak, whence it stretches due west, being bounded to the south by the districts of Khushab, Mitta, Tuwanah and Kuchi. In this extent of 130 miles, with a range of hills traversing the centre, it is natural that the character of the country should vary much, the ravine country to the north, the hills of the centre, and the fine fertile plains to the south, are well marked distinctions.—*Jour. Ben. As. No. 1 of 1850*, p. 644.

(881) JOHORE ARCHIPELAGO. This extensive Archipelago is formed by the prolongation of the plutonic zone of elevation of the Malay Peninsula from Singapore to Billiton. These islands, with the exception of a few of the most southerly, formed the insular part of the kingdom

## KAF.

of Johore from the 13th century to the occupation, in 1820, of Singapore.

(882) JOOZ, *Arab.* A section of the Koran.

(883) JOQINI TANTRO, a work of high repute in Assam, its contents are supposed to have been communicated by Siva to his consort Parbati. It is stated, regarding the king Norok, that though an "Osor" infidel, he was in such favour with the gods that they made him the guardian of the temple Kamikhya. It is not improbable, that the temple was originally erected by Norok, but of this we have no certain evidence. The assertion made in the Tantro, however, would, at least, lead us to suppose that the temple was in existence in his days.—*Jour. As. Soc. of Ben. No. 1 of 1855, Robinson's M.S.*

(884) JUMBAGUM MARUM. *PTEROCARPUS* sp. Common about Nelambore and Wynaad, a large tree, wood used for building and fencing gardens, said to be durable.—*McIvor. M. E.*

## KALAYUM.

(885) JUMNOMUNDROO. This Nepaul tree bears yellow sweet-smelling flowers in branches; its leaves resemble those of the holly and the wood is, both in closeness of texture and colour, very like box.—*Smith's Nepaul.*

(886) JUNIPERUS EXCELSA. Pencil cedar of Kooloo.

Shoor, also Lewr, HIND. | Dhoop, HIND.

(887) JUNIPERUS COMMUNIS. Creeping Cypress of Himalayan travellers.

Purpinja, HIND. | Chee Chia, HIND.  
Budma, HIND.

(888) JUNIPERUS RECURVA.

Khoubair, HIND. | Ubhul, HIND.

(889) JUNIPERUS RELIGIOSA.

Googul, HIND.

(890) JUNIPERUS SQUAMOSA.

Pama, HIND. | Theloo, HIND.

## K.

(891) KACHULA CHULA, *Malay*, (instead of tandock) is the name given to hard horns or horn like parts of animals, believed to possess magical or medicinal properties. Lang Limu [ilmu] kahutan katungalan. The Malays cannot affix any definite meaning to the first two lines. The rendering would perhaps be [magical] science for protection when alone in the forest, or to make the offerer alone as when surrounded by a forest.—*Jour of the Indian Archl. December, 1847, page 309.*

(892) KADDA PILOW, the Tamil name of a tree, which is the river side Jackwood. It is inferior to the wood of that name: the natives use it for inferior purposes in small pattamahs and coasting-vessels. It is not of much value.—*Edye, M. and C.*

(893) KADIR WULLEE, a Mahomedan Saint whose tomb is at Negapatam. His Ooroos, is held on the eleventh day of the sixth month, Jemadi-ool-Akhir.

(894) KAF.

Koh-i-kaf, PERS.

*Mount Kaf*, is the fabulous mountain which, according to oriental cosmographers, surrounded the world (apparently to prevent those at the extremities from falling off,) but since the science of geography has made some progress in the East the name has been confined to Mount Imaus to the East, and Mount Atlas to the West. The Genii, a race intermediate between angels and men, produced of fire, are supposed to have inhabited the earth for several ages before the birth of Adam, and to have been governed by Kings, all of whom were called Soleiman (Solomon.)

They fell into a general state of depravity and were driven into remote places by Eblis (the fallen angel) and such as remained in the time of Caïumeras, the first of the Peisdadian dynasty of Persia, were by him driven to Mount Kaf.—*Journ. Ind. Arch., Vol. V, No. 9, page 548.*

(895) KAHLARU, the Malayala name of one of the jungle-trees. It grows to about seventeen feet in height, and seven inches in diameter; is very hard, close grained, and strong; and is used by the natives in boats, and for timbers, and knees in vessels.—*Edye, M. and C.*

(896) KAHOLO, a Nepaul Wood. Of the Kâholo, the poorer classes of the people, in time of scarcity, prepare a nutritious bread, which is sometimes mixed with flour.

(897) KAJAH, the Malayala name of a tree which grows to about eight feet in height, and ten inches in diameter; it is very strong, and the crooks of it are used by the carpenters for boat work.—*Edye, M. and C.*

(898) KAJUL.

Kajul, HIND.

Lamp-black.

(899) KALAYUM in Tamil, and Condle in Malayala. This tree grows from ten to fifteen feet in length, and from twelve to eighteen inches in diameter; its branches at the top are very thick; the wood is of a reddish cast, and much like the pencil cedar; it grows on the banks of rivers, but is not of much value for any purpose. The tree produces a fruit which I could not find was of use either to man or beast.—*Edye, M. and C.*

## KARANGELY.

### (900) KA-LING.

Ka-ling, BURMESE.

A tree grows twenty or thirty feet high, generally wild. The fruit is the size of a child's marble, used more as medicine than food.

(901) KALLOW MOW, the Malayala name of a tree which grows to above sixteen inches in diameter, and twenty feet in height. It produces a nut which is food for monkeys and other animals of the forest, the wood is used for various purposes, but is of little value.—*Edye, M. and C.*

(902) KALUDUMUM, the Tamil name of a tree which is remarkably heavy and very close-grained, and much resembles the English pear-tree wood; it grows to about eighteen inches in diameter, and from twelve to fifteen feet long: it is used for purposes where strength is required. I should expect that it is not very durable, or that it is not to be procured in any quantity, as it is but little known.—*Edye, M. and C.*

(903) KAMALAH, the Tamil name of a tree which very much resembles the wood in Ceylon named Halmille and Somendille; its growth is about thirty feet long, and two feet in diameter; it is used for much the same purposes as the other jungle-woods, in vessels and house-work; and the crooks are similar to the last-named.—*Edye M. and C.*

(904) KAMBALLOO, a product of an umbelliferous plant used by Burmese ladies as a cosmetic for the face.—*Cat. in M. Ex. of 1857.*

### (905) KAN.

Kan, BURMESE.

Is a shrub, three or four feet high, yielding a valued fruit which resembles a sweet grape.—*Malcom, Vol. 1. p. 52.*

### (906) KA-NA-ZOO.

Ka-na-zoo, BUR.

Soondry-tree. Vide (*Heritiera*.)

(907) KANDOBA. Is next to Wittoba, the most popular object of worship among the Mah-rattas, and his most famous temple is at Jejuri, near Poona.—*Chow Chow, p. 262.*

(908) KANGU VITTU, the Malayala name of a tree which grows to about sixteen feet high, and eight inches in diameter. It is one of the jungle-trees of the coast.—*Edye, M. and C.*

(909) KARA-KUNDLE, the name of a tree that grows in the Malabar and Travancore forests to about sixty feet in height, and two feet in diameter. It is used by the Arabs for masts of dowses, buggerows, donis, and patta-mahs. It is very strong, and is said to be durable; but must be considered heavy for the purposes to which it is applied.—*Edye, M. & C.*

(910) KARANGELY in Tamil, and Karakili in Malayala. This wood is very tough and of a whitish colour, and used by the natives for general purposes; many of the planks of the native boats are of this wood, and the edges are sewed together with Koir, with wadding on the

## KARLEN.

seams, and yarns crossing the joints, for the purpose of making the boats pliable in the surf, as it would be useless to fasten them with nails, &c. for the services for which they are required.—*Edye M. and C.*

(911) KAREN. A race scattered throughout the Burmese, throughout all the wildest and most secluded parts of Pegu and Martaban as well as Tenasserim, and the western parts of Siam. There are two tribes known, one of these call themselves Shos, but are called by the other tribe "Pwos" and by the Burmese Meet-khyeens, or Talain karens. The other tribe call themselves Sgaus, but by the Burmese are designated Meethos, or Burman karens. They are most populous in the Bassein district, where they form the great bulk of the agricultural population, the Burmese and Talains being principally small traders, fishermen and mechanics. After the cession of Arracan to us, the Karens spread largely over the hills into the district of Sandowa. In the northern parts of Pegu, on the side of the Irawaddi, the Karens are few and sparse and they have not been heard of further north in Burmah than the district of Tsalen.

(912) KAREOVAM, the Malayala name of a tree which grows to about eight inches in diameter, and twelve feet long. It is generally curved, and used for the frames of native vessels, and for agricultural purposes. It is known as jungle-wood.—*Edye, M. and C.*

(913) KARINCOLU in Tamil, and Karinjurah in Malayala. This tree grows to twelve or fourteen feet long, and twelve inches in diameter; it is of a whitish cast, and not of much use or durability. It produces a fruit which the natives eat in a raw state.—*Edye, M. and C.*

(914) KARINDAGARAH, the Tamil name of a tree which grows to about forty feet in height, and eighteen inches in diameter. It is used by the native carpenters in house and ship-building, and for various purposes. It is not found in any quantity, and consequently it is not much known.—*Edye, M. & C.*

(915) KARINGATTA, the Malayala name of a soft, light wood, which is preferred by the natives for the soles of sandals, &c. It grows to about twelve feet high, and eight inches in diameter. It produces a fruit from which oil is extracted. This, with the leaves of the tree, is used for gout and rheumatic pains.—*Edye, M. and C.*

(916) KARLEN. Here, as also at Junir on the Ghauts, and Kuden or Korah in the Concan, as also at Kanheri and Nasik, are caves containing inscriptions in Deva nagari, known as Sahyadri. These contain inscriptions, excavated at various dates from before Christ 200 years, to A. D. 460, the oldest, those at Karlen and the newest those at Kuden, in the Concan, the seven centuries during which Buddhism flourished in western India, while the modern Hindu system was

silently moulding itself into its present form, and preparing to take the place, at a somewhat later period of the religion of Buddha, and to exhibit that compound of Vedic pantheism and Buddhistical tenderness for animal life and indigeneal superstition that is now current in India.—*Dr. Stephenson in Bom. As. Soc. Jour. No. XIV. Vol. V. of 1854.*

(917) KARNARA VETTE, the name of a wood which the native carpenters use for boat work, and small vessels. It ranks amongst the numerous jungle-woods, and grows only to twelve inches in diameter, and about fifteen feet high. It is not of much consideration as to quality, quantity, or durability.—*Edye, M. and C.*

(918) KARNATAGARAI, in Tamil and Malayala. This tree is a close-grained firm wood; when old it resembles the Vitte Marum, or black wood of Malabar, known in England by the name of Bombay black or rose wood. It grows from twenty-five to thirty-five feet long, and two feet in diameter; it is used for furniture and house-building: it grows straight, and is found in patches on the Ghats, east of Cochin.—*Edye M. and C.*

(919) KARROO VAGOO: PTEROCARPUS, Sp. A very common tree on the western Ghats, wood strong, durable and much used for building.—*M. E. J. R.*

(920) KATHUKEVI, the Tamil name of a tree which grows in Travancore. It is very buoyant, and is generally used for rafting the heavy timber from the forests; and also for catamarans and canoes, as it is easily worked, and obtained without much trouble, and of all dimensions. It is not very durable.—*Edye, M. and C.*

(921) KAYANS. Mr. Dalton states that the Kayans amount to 270,000 souls, and that they were greatly addicted to head hunting.

This people inhabit the North-West of Borneo, in the interior of the country comprised between the rivers Baram and Rajang, which with the small rivers intervening allow the Kayans access to the ocean. The mongrel malays occupy the coast, and the country between them and the Kayans is occupied by eleven other tribes in number each about 500, the majority of whom are subject to the Kayans. The Kanawit tribe closely assimilate to the Dyaks of Saribas, whose neighbours they are. The tribes Punan, Sakapan and Kajaman are the chief collectors of camphor and birds nests. The Kayans are a nation of prostitutes, they are not so passionately fond of skulls as to bequeath them as fortunes to their children as is said of the Dyaks. They continue human sacrifices, but to a less extent. The Kayan name for God is Tanangan, whom they hold to be invisible and supreme. The coal and iron fields of the Balawi or Rajang are more extensive than any yet discovered on the Island. From the river Baram, coal is traced

to the upper parts of the Bintulu, and thence southward to the Rajang river, on the left bank of which at Tujol Nang, there is a seam exposed upwards of thirteen feet in thickness. *Mr. Burns in Feb. 1849, No. of Jour. Ind. Arch.*

(922) KEADIE, or perhaps, HEADIE, the Malayala name of a tree in the forests of Canara. It grows from eighteen inches to two feet in diameter, and from thirty to fifty feet high. It is a close-grained wood, and is said to be durable; but it is rather scarce.—*Edye, M. and C.*

(923) KEE. Burm. *Syndesmis lavoyana*, of Wallich.

(924) KERBELA or Mesched Hoossein, is situated a short distance from the West bank of the Euphrates, and not very far from Hillah, the supposed site of Babylon. It is surrounded by gardens and groves of palm trees which are watered by a canal from the river. The chief object of interest is the Mosque, built in the reign of Shah Abas the Great, on the spot where Hoossein the son of Ali, nephew of and son-in-law of the Prophet, was murdered. It is a sacred place of pilgrimage and burial to the Persians who are Sheaites, that is who acknowledge the Caliphate of Ali: by the Turks, however who are Sounites, and do not believe that Ali was the rightful Caliph, it is held in no peculiar veneration, hence though no Christian is allowed to enter the precincts of the Mosque, a Turk whose house overlooked the court, made no objection to a traveller going up on his roof and making a sketch. Kerbela fell into the power of the Turks when Sultan Murad IV. took Baghdad A. D. 1636.

The Persians frequently send their dead to be buried at Kerbela, from the interior of the country. On leaving Kerbela the traveller met nine mules laden with coffins, and while at Baghdad he often saw others passing to their last resting place near the honoured remains of the grandson of the prophet.

(925) KERBELA. In India, a plain near the sea or any river or tank, whither the Mahomedans annually carry their Taboots.—*Herklots.*

(926) KEWN, Burm. Teak. *Tectona grandis.*

(927) KHAKSI. A curious Nepaul shrub called the Khaksi, the leaf of which answers the purpose of emery or sand paper, giving a fine polish to the harder woods.—*Smith's Five Years in Nepaul, p. 68.*

(928) KHIZR. Khaja khizr, a festival held in Northern India on the Fridays of the month Shaban, said to be in commemoration of Elisha or Elijah.

(929) KHONNAY, in Tamil, Kakay in Malayala and Carnataka. This tree grows to thirty feet long and from twelve to eighteen inches in diameter; it is curved in growth; is rather close-grained and heavy; and very much resembles the Maragosa in Ceylon; but it is rather scarce

## KORINGI MARAM.

on the coast of Malabar. It produces the pod known by the name of *Cassia fistula*, or Banda lotte, which is considered an excellent purgative in case of habitual constipation, both by natives and Europeans.—*Edye, M. and C.*

(930) KHUTEEB, ARAB. A mahomedan preacher who reads the Khootba.

(931) KIAONG, the name given in Burmah to the monastery houses of the Phongis, or Bhudist Priests or monks.

(932) KINA BALOW, a mountain near Bawang, in the Archipelago estimated between 13,000 and 14,000 feet in elevation.—*Journ. Ind. Arch.*

(933) KIPPONG, a tree, the bark of which is chiefly used, both at Johore and by the Berman tribes, for the sides of their houses.

(934) KITE-FLYING is a pastime universally practised amongst the Chinese, who excel all other people both in the varied forms of their kites and the heights to which they can make them rise. They are constructed of paper made of refuse silk and bamboo. They assume every possible shape, and sometimes it is impossible when they have reached the culminating point, to distinguish them from birds. By means of round holes, supplied with vibrating cords, on which the current of the air acts, the kites when ascending, issue a humming noise, similar to the hum of a swarm of bees.

(935) KOIK-PAH, the Malayala name of a tree which answers the purpose of small spars for native vessels: it is said to be strong and durable for such purposes.—*Edye, M. and C.*

(936) KOOKIE. In a *slight notice of the Grammar of the Kookie language*, by Lieut. R. Stewart, 22nd Regiment B. N. I., he says that the people to whom the term Kookie is given by the inhabitants of the Eastern Frontier of Bengal, occupy, together with other tribes, the hilly tracts lying to the North, South and East of Cachar, and Manipoor: they are divided into numerous clans each under a petty hereditary chief or Rajah.

The appellation of Kookie is unknown among themselves, and they have no title embracing their whole race, but they call one another by the names of their different clans.

They all speak the same language, with very slight modification in the dialects, and it is called among them Thadou Pao, from the name of one of their principal clans.—*Jour. Beng. As. Soc. No 3 of 1858.*

(937) KORAH, a short but heavy Nepaul weapon of a half moon shape, the edge of which is on the inner side like that of a scythe.—*Smith's Nepaul, p. 170.*

(938) KORA-KORUM. A pass in the chain of Kuen-luen, 18,300 feet high.

(939) KORINGI MARAM, or Horingi-maram, the Tamil name of a tree which produces the soap-nut, or rather the soap-apple, which the natives use as a substitute for soap. This tree is

## KURVAH TANGA MARAM.

common on the Malabar Coast, and grows to about eighteen inches in diameter, and twenty feet long. It is used by the carpenters for many purposes. There is another sort named Horingi Tanga Maram, which is the jungle or wild soap-tree. The apple is very inferior in size and quality to the former, and the tree nothing more than jungle or underwood. The soap-apples are gathered and sold in the bazar at all seasons of the year, and answer the purposes of soap for washing.—*Edye, M. and C.*

(940) KUB-LO-WAH. Burm. (*Laurus*).

(941) KUBO, is the name applied to the Shans in the Manipur language.

(942) KUEN LUEN, a chain of mountains in Thibet, which are as lofty as the Himalayas, where the chain forms the western boundary of Thibet.

(943) KULBAGI, the name of a tree in Canara. It grows to fifteen or twenty-five feet in height, and from twenty-four to thirty-six inches in diameter. It is a close-grained, hard and durable wood, and is used by the natives at Mangalore and Honore for the keels and beams of vessels. It is of a dark colour, and is considered valuable.—*Edye, M. and C.*

(944) KULMAH, Arab. THE CREED or the Kulma shahadat, used by the Mahomedans means "I bear witness that there is no deity save God, who is the one and has no co-equal; and I bear witness that Mahomed is his servant and is sent from him."—*Her. k.*

(945) KUNDU PALE, or Hundu Pale, a tree which produces a fruit. It grows to about eighteen inches in diameter, and twenty feet high. It is not of much use excepting for its fruit, which is eaten by the natives and by wild animals.—*Edye, M. and C.*

(946) KUNJEERAM MARUM or POISON TREE. *Strychnos Nux-Vomica*, a small tree very common about Nelumbore, wood strong and elastic, much used for tool handles.—*M. E. J. R.*

(947) KUN-NE-AN. Burm. (*Myristica*.)

(948) KUN-NYIN-BEN, and KUN-NYIN SE, Burm. (*Dipterocarpus*.)

(949) KURBEE, Hind. This name is given to the stalks, cut small, of the sufaid Joar, or Saonulee, the Sorghum vulgare, and in this state is extensively used for feeding cattle.

(950) KURUTU-PALAH, the Malayala name of a tree which grows to about eighteen feet long and eight inches in diameter. It is very close in its grain, and remarkably hard and strong. It produces a fruit which is eaten medicinally; but the wood is not much used in consequence of the labour required in working it.—*Edye, M. and C.*

(951) KURVAH TANGA MARAM, which is the wild cinnamon-wood tree of the jungle. It grows to about twenty or thirty feet high, and from twelve to fifteen inches in diameter: it is

very scarce, and consequently not much known or used.—*Edye, M. and C.*

(952) KYET-MOUK, *Burm.* or COCKSCOMB, is a moderate sized tree, found wild in

most parts of the Burmese country. The fruit is red, sour, and the colour of a cock's-comb, and has similar corrugations on the skin. It hangs in grape-like clusters.—*Malcom, VI, p. 181.*

L.

(953) LABUAN. *Report on the Geological Phenomena of the island of Labuan and neighbourhood. By J. Motley, Esq. in the Journal of the Indian Archipelago, Vol. VI. No. 10.*

The island of Labuan on the N. W. coast of Borneo, and now a British settlement, is in shape, a sort of triangle, of which the longest side, running about N. E. and S. W., is 11 or 12 miles in length and approaches a straight line. The coast line is, for the most part, flat and sandy, although in one or two places, low cliffs abut upon the sea and at about the centre a sloping cliff, 100 feet high or more, leads out to a long sunken ridge of rocks, terminated by a rocky islet named Lyang Lyangan. At this point, deep water may be found up to the beach; but elsewhere shoals and coral reefs extend to a great distance from the land. The southern side of about 6 or 7 miles in extent from E. to W., is indented by a broad bay having for the most part very shoal water, from the bottom of which a considerable stream, the China river, pursuing a very tortuous course through mangrove swamps but in a general N. and S. direction, divides the island for about 2-3rds of its length into two nearly equal parts. Victoria harbour may be considered a part of this bay, for it is probable, though not certain, that the mangrove swamp at its head is continuous or nearly so with that bordering the China river, so as to separate the range of low hills on the west of the harbour from the rest of the island. From the opposite sides of this bay two ridges of hills, probably nowhere more than 200 feet in height, converge towards the head of the China river, the most elevated parts probably occupying about the central lines of the two divisions and forming the water-shed between the central mangrove swamps and the ravines of the eastern and western shores. Besides the main central drainage of the China river, there are upon this coast several minor creeks, dignified by the name of rivers, which penetrate but a short distance into the jungle.

The dependant islets of Labuan, with the one exception just mentioned, all lie to the south, and proceeding from W. to E. are as follows:—Pulo Kuraman, consisting of a long low ridge and a good deal of sandy beach, is about  $1\frac{1}{2}$  miles in length and is situated a little to the S. W. of Tanjong Kiamsana the west

point of Labuan. Eastward of it is Pulo Burong, opposite the mouth of the China river, a round mass of limestone rock about 50 or 60 feet high. Off Tanjong Ranche Ranche, to the west of Victoria harbour, is Pulo Belulang, a small limestone rock, and south of it is Pulo Enoo, a small hill surrounded by extensive sandy tideway. On the east of the harbour entrance lies Pulo Kulin Pappan, a small ridge with sandy beach on each side, and connected by a line of rocks, for the most part sunken, with Pulo Daaf, which is the largest of the islands, being 4 or 5 miles in circumference, and containing several hills 80 or 90 feet high. Still eastward and in the mouth of the Kalleas river, passing over an island named Labungan, is Pulo Malan Kassam, which by some mistake in the naming of the early charts was ceded without the intervening island. All these islands are nearly in a straight line. To the southward of Kuraman are Oosookan Kichil and Oosookan Besar, rocky islets with a little flat sandy plain and surrounded by very foul and dangerous ground.

The eastern side of the island forms also a shallow bay almost filled with coral reefs and sand banks, and partially fringed with mangroves. Towards the north another smaller river, the Gangarak, drains a considerable extent of country, chiefly swampy, producing a luxuriant vegetation of various palms and mangroves, and the greater part of it hardly elevated above the level of the sea. Its sources are, for the most part, to the southward of its debouchment, though one small branch runs in a northerly direction, and they are divided from those of the China river by the united northern extremities of the two ridges before mentioned, which are here, for the most part, very low.

The measures of which the whole island is composed are alternating clays and sandstones, with all the intermediate modifications usually found in an English coal field, but having throughout the appearance of having been exposed to much less pressure and condensation. Coal occurs in several places, and the veins appear to be associated in groups. In one place five, in another three veins (one very small) are distributed in a very small space of ground, and in each case, the containing group of clays is placed between two very thick

## LAC.

beds of sandstone. The clays are usually very slightly laminated, excepting where they are alternated with sandstone in excessively thin beds, a formation rather common. They are also much less carbonaceous in general than the corresponding members of the Welsh and north of England coal fields, but to this there are some exceptions. One bed of blue shale, apparently of considerable thickness, yields in several places small springs of dark coloured but tolerably pure petroleum. This bed is in perpendicular depth some 400 or 500 yards below the principal coal seam. No regular beds or veins of ironstone have been detected though the clays frequently contain nodules of argillaceous iron ore, sometimes in nearly continuous courses. These nodules are often septarian, and are filled with crystallized but very friable carbonate of lime. Small masses of arsenical pyrites are also sometimes enclosed in them, as well as in the clays themselves. These nodules when exposed to the air, appear in the course of a great length of time, to become converted into a red oxide of iron of various degrees of hardness, from a powdery yellow soft substance, to a dense dull purple cavernous stone of vitrified appearance, capable of striking fire with steel and closely resembling the laterite of Singapore. The whole surface soil of the island and the beds of most of the streams are more or less covered with scattered masses of this substance. It is also found on the main land, and is the ore from which the Kadyans and Moorats, native tribes in the neighbourhood of Brunei, manufacture their iron.

The coal is of very good quality, hard, dense and with a fracture inclining to conchoidal, and is remarkable for having dispersed through its substance masses of imperfect amber, sometimes light yellow and very transparent, sometimes approaching to black and in a semi-carbonized state, but always extremely friable and brittle; when burnt it diffuses the fragrant smell of recent resin, and is in a sufficiently perfect state to be collected by the workmen and used with fresh dammar in making torches. In some seams of coal on the river Bintula, to the south of Brunei, the late Mr. Burns mentioned that almost half the seam consists of this substance, which is there commonly dug and used by the inhabitants as dammar. Specimens of coal from Ritch, on the east coast of Sumatra near the Indrageri, contain much of this substance.—*J. Motley Esquire, in Jour. Ind. Arch. Vol. VI. No. 10, Oct. 1852.*

(954) LAC. The lac which is largely exported from Burmah, is obtained chiefly in the Shyan districts. It is the product of an insect, (*Coccus lacca* of Linnaeus,) which exudes the gummy matter upon twigs, to protect its eggs, and creates a sort of habitation. It lives on

## LAMPONG DISTRICTS.

various trees; in Assam, chiefly on the *Ficus religiosa*.—*Malcom.*

(955) LA-HOUL-O-LA-QOOWUT, &c. *Arab.* Meaning there is no power or strength but in God, these are the commencing words of a Mahomedan invocation.—*Herk.*

(956) LA-IL-LA-HAH, IL-LUL-LA-HO, *Mahomed oor-Russool Oollahay*, which signifies there is no other deity except the one true God, and Mahomed is the prophet (or messenger) sent by God.—*Herk.*

(957) LA-MOO, *Burmese.* Is a small tree, like a willow, growing only near salt water, and generally on the very edge, twelve or fifteen inches in diameter. The blossom is very beautiful, a little like a thistle, very fragrant, pale-green, large umbrella-shaped pistil, innumerable stamens, no corolla, but a thick calyx, which remains, and holds the fruit like a dish. Monkeys are fond of the fruit, and are often seen in the tree. The natives use it in curry. Timber useless.—*Malcom, Vol. I, p. 181.*

(958) LAMPONG DISTRICTS OF SUMATRA. The size of these districts is about 12,926 square English miles. Their maritime boundaries are formed on the South by the Indian Sea and the Straits of Sunda, and on the East by Java, whilst the rivers Masuji and Pisang bound it on the north and west.

Tobacco is planted here and there, but it does not constitute an article of export. The leaves do not grow very large, but have a fine flavour. The inhabitants of the Lampongs deem their tobacco better than that of Java and will not buy or use the latter. It is probable that the difference consists more in the preparation of the produce than in the plant itself. In the markets, tobacco is sold according to the weight of the copper money, i. e. the buyer receives for his copper money, as much tobacco as the doits weigh.

The forests produce some articles of merchandise, which are of great importance to such a poor country. The first of these is the rattan both the pliable rattan and the cane, which are found in considerable quantities, and which are exported to Singapore as well as to Batavia. The cane (*calamus rotang* L.) is called in the Lampongs "*semambu*." In a botanical point of view the country is very rich in species of these, and allied genera. The inhabitants of Tarabangi enumerated besides the *Semambu*, the following species:—

2	<i>rotlan bubwar</i> or <i>bubar buwar.</i>		
3	„ <i>bunkua.</i>	10	„ <i>Lakki.</i>
4	„ <i>Kommoran.</i>	11	„ <i>Sabuk.</i>
5	„ <i>Semuly</i> or <i>jemang.</i>	12	„ <i>Peledes.</i>
		13	„ <i>Sessak.</i>
6	„ <i>Suti.</i>	14	„ <i>Tungal.</i>
7	„ <i>Urang.</i>	15	„ <i>Bobras</i> and
8	„ <i>Balk.</i>	16	„ <i>Manu.</i>
9	„ <i>Kayu.</i>		

## LAMPONG DISTRICTS.

The *calamus draco* L., is only first found further to the north-west, for example in the plains of Palembang; at all events not on this side of Tulang Bawang.

The country is unusually rich in plants which yield gum, and that not only for trade but for daily use in the houses of the inhabitants. The kind of gum most sought for is the "*dammar kacha*," also called "*dammar mata kuching*." The extraordinary high price which this article for some years maintained in the European market, has now fallen considerably, and during my sojourn at Telok Betong some prahus laden with dammar returned from Batavia because dammar could only be disposed of there at unusually low prices. The greatest use is made of some other sorts for candles and flambeaus, as scarcely any oil is burnt in the interior. Some periods of the day are even named according to the time of lighting the rosin flambeaus. In Tarabangi I heard the names of the following kinds of dammar, or rather I have to thank Mr. Juch for the communication of these names, viz.

1. *Dammar kacha* or *mata kuching*. From a high tree which grows in the vicinity of the southern coast.

2 *Dammar kuyung* used for flambeaus.

3 „ *Assem.* 6 „ *Hulu tupay.*

4 „ *Barinti.* 7 „ *Bunu.*

5 „ *Seburu.* 8 „ *Karuwing* or *bangbang*. Probably the thick oil, tough and quickly drying of the *Hernandia sonora*, called "bunka" by the Bugis. Could we not employ this in making tea boxes?

9 *Dammar tahala.*

10 „ *Selunay*, from the *Mengarawan* tree, which is the wood most sought after in the Lampongs for building. I could not classify it botanically.

11 *Dammar tambikat.*

12 „ *Sali-siep.*

13 „ *Kenbutul.*

14 „ *batu* or *serem* for flambeaus.

15 „ *dagin meira*, which runs of itself from the trunk.

16 *Dammar Mahalu*, makes a good cement.

The Lampongs possesses three species of ape which are not found in Java. The *Orang Outan* appears to be even less native than on Java. Besides tigers and panthers, two smaller species of cats also occur, which are strangers to the island of Java, as also another kind of *Viverra* and *Mustela*. The Malayan bear and the elephant are also wanting on Java. In place of the rhinoceros of the last we find there the *Rhinoceros sumatrensis*, and in place of the *Cervus russa* we find there the *cervus equinus*.

The *tapir* probably has his habitat towards the frontiers of Palembang, and on the other hand the *banteng* (*Bos sundaicus*), which is spread over the whole of Java, is wanting.

The bear is called "*gemol*" in the Lampongs.

## LAMPONG DISTRICTS.

The beautiful *Argus pheasant* occurs, which it is difficult to export, because it easily sickens and dies on the voyage. Its eyes are first affected, afterwards follows a complete blindness, then a swelling of the whole head and throat, and shortly afterwards it dies. The natives call the bird *ku-wau*. Its manner of living agrees entirely with that of the peacock.

The inhabitants of the Lampongs are aborigines in the true sense of the word, because there are very few strangers there. There are Europeans at Tarabangi, 2 or 3 Chinese at Telok Betong; Bugis and Javanese on the coast and at the places where most trade is carried on. Of the foreigners the Bugis are most numerous, and they principally reside at Telok Betong, Mengala and Siring Kebo. The true aborigines of the Lampongs differ little from the Sundanese on Java, and clearly belong to the same race. They are not larger and are less muscular than the latter. In particular we do not find amongst any of them the round broad faces, short legs, and the coarse large feet, which are so frequently met with amongst the Sundanese. The difference is most marked in the female sex, who are favourably distinguished in the Lampongs by finely formed feet and hands, by a fairer colour of the skin and a softer and slightly pensive expression of the eyes. That the colour of the skin is less dark brown, may be ascribed to the circumstance that the female sex pass the greater part of their lives in well closed houses. The dress of the men is exactly the same as in the west of Java.

The Lampong fair ones delight much in finery, which however they only wear so long as they remain unmarried. As wives they do not make any further use of their ornaments. We find:

1st. *Bands for the forehead*, which consist either of resin-beads strung together and covered with silver or gold and are called *jelemeni*; or are made of a thin stripe of bambu to one end of which their gold leaves are sewed while the other remains loose. This kind is called *kembany pandan*. A cincture of gold leaf in the form of a hoop is called *Kandu Keda*.

2nd. *Bracelets*.—These, which consist of the before mentioned beads, are called *piko*: those of gold and silver leaves, *gale pepe*; those of resin rings covered with gold, *gelang*.

3rd. *Necklaces*, of gold leaf or silver leaf, gold and silver thread, *tad gala*.

4th.—*Bangles*, or ankle rings of gold or silver, *gale chalu*.

5th.—*Eur-needles*, with gold or silver crowns, *chundok*.

6th.—This is not yet the whole. A girl who would be fully adorned, must affix silver nails to her fingers. There are very short ones called *singai*; and very long ones, which look like claws, called *tanggai*, which are principally used in dancing.

# LAMPONG DISTRICTS.

# LAMPONG DISTRICTS.

All the houses in the Lampongs stand on high posts. They are built so beautifully, so strongly and so fitly, especially in the interior of the country, that we cannot sufficiently admire the patience, activity and art of the inhabitants, particularly when we consider what small me-

chanical means the builders have at their service and how few and rude are the instruments which they employ. The houses consist altogether of wood with the exception of the floor, but including the roof, which is made of good shingles (*airaps*).—*Jour. Ind. Arch. Vol. No. 12.*

Mengala	...	3,616.
Siring Kibo	...	12,435.
	550	67,684.

## LEAD.

(959) **LANTERN FEAST.** The feast of lanterns, amongst the Chinese, takes place on the first full moon of the new year. It affords opportunity for a display of ingenuity and taste, in the construction and mechanism of a variety of lanterns made of silk, varnish, horn, paper and glass, some of which are supplied with moving figures of men galloping on horse back, fighting, or performing various feats, together with representations of birds, beasts and other living creatures all in full motion. The moving principle in these is formed by a horizontal wheel, turned by the draft of air created by the heat of the lamp, and the circular motion is communicated in various directions, by means of fine threads attached to the moveable figures.—*Davies.*

(960) **LARIX GRIFITHII**, "Sah", HIND. This Himalayan Larch splits well, and is the most durable of any; but the planks are small, soft and white.—*Hook. Vol. II. p. 45.*

(961) **LAURUS** (The *Kullowah* Bur.) is an inferior sort of camphor-wood. Bark fragrant.—*Malcom's South Eastern Asia, Vol. 1, p. 191.*

(962) **LAURUS PARTHENOXYLON**. (*W. J.*) *Enneandria Monogynia. Kayo Gadis.* Malay. This is a lofty timber tree, abundant in the forests of Sumatra. This species has considerable affinity to *L. cupularia*. The fruit has a strong balsamic smell and yields an oil, which is considered useful in Rheumatic affections, and has the same balsamic odour as the fruit itself. An infusion of the root is drank in the same manner as Sassafras, which it appears to resemble in its qualities. The wood is strong and durable when not exposed to wet, and in that case considered equal to teak. Kayo Gadis signifies the virgin tree, whence the specific name.

May this be the oriental Sassafras wood mentioned under the article Laurus in Rees' Cyclopædia.—*William Jack in Calcutta Journal of Natural History, Vol. V. p. 354.*

(963) **LAVENDULA CARNOSA**. Lin.  
Karpoorawullie, TAM. | Vurdefrasoon, ARAB.  
Silake, pungerie, DUK. | Barage, SANS.  
*Ainslie, p. 253.*

(964) **LAZ-UN**, Burm. *Pongamia atropurpurea*.)

(965) **LEAD.** The old Lead Mines of Kohel lie near the Red Sea, a day's journey N. by E. from *Gebel Zubara*, in about Lat. 24° 40'. Not far distant are the Lead Mines of *Gebel Rassas*, lit. Mountain of Lead.

The Mines are situated about 1½ mile from the W. shore of the Red Sea, as before observed. The ore, galena and carbonate of lead, occurs in an argillo-siliceous schist, associated with small quantities of sulphur and iron—a poor carbonate. A Bey visited seven excavations, which are mostly from three to four feet broad, about five feet high, and run down in inclined planes cut in steps. Galena was found in the shaft worked by Brochi; but the indications discovered

## LEPUS HISPIDUS.

are not considered favourable. Besides other minerals, titanated iron, manganese, zinc and fire-clay have been discovered here. The surface of the rock between the mines and the shore is coral limestone, covered with a gravel of granitic gneiss, porphyry pebbles.

The mines were worked by the ancients; and the ruins of an old, but not extensive station still exist, in detached buildings of loose stones and foundations—some round,—others square. Water is brought from *Gebel Egleh*, or *Edjleh*, four or five hours' distance.—*Newbold.*

(966) **LEEZAN**. The village of Leezan consists of scattered houses on the side of a hill which slopes down to the river Zaab.

A mountain stream empties itself into the river at the foot of the village, which it separates from the church.

During the massacre of the Nestorians by the Koords, the inhabitants of Leezan took refuge upon a platform on the rock above the church, where they defied all the attempts of Beda Khan Bey to dislodge them. But being at last starved out, they capitulated on the understanding that they were to surrender their arms and property, and their lives to be spared.

The Koords on being admitted to the platform and having taken the arms, commenced an indiscriminate slaughter, but few persons throughout the entire valley escaped this terrible massacre.

(967) **LEP-HAN**, BURM. Grows everywhere in the upper provinces, and is one of the largest trees in the country, often ten and twelve feet in diameter. The ripe seeds are contained in pods, enveloped in a fine cotton, of which mattresses are commonly made. Both blossoms and fruit are eaten when young, chiefly in curry. Timber inferior.—*Malcom, Vol. 1, p. 181.*

(968) **LEPUS HISPIDUS**. PEARSON: *CAPROLAGUS HISPIDUS*, Blyth, *the Hispid Hare of the Saul forest*. Habitat. The great forest at the base of the Sub-Himalayas and of their off-sets, from Gorakpur to Tipperah.

This primeval forest is the peculiar and exclusive habitat of the Hispid Hare, a species that never ventures into the open plains on the one hand, or into the mountains on the other; and hence it is so little known, deep cover and deadly malaria contributing alike to its happy obscurity. As the black-necked Hare or *L. Nigricollis* is the single species of the Deccan, and the Redtail, *L. Ruficaudata* of Hindostan and Bengal, so is the Hispid of the vast Sub-Himalayan forest; and it is remarkable that the mountains beyond the forest, even up to the perpetual snows, have no peculiar species.

The Black Hare or Saul forest Hare, both excellent names—feeds chiefly on roots and the bark of trees, a circumstance as remarkably in harmony with the extraordinary rodent power of its structure as are its small eyes and ears, weighty body and short strong legs, with what

## LEPUS SINENSIS.

has been just stated relative to the rest of its habits. The whole forms a beautiful instance of adaptation without the slightest change of organism.

The sexes are as near as possible of the same size and colour; but, if anything, the male is rather the larger and darker. The male measures  $19\frac{1}{2}$  inches from snout to vent—head to the occiput, 4.; ears to the lobe  $2\frac{7}{8}$ ; to the crown  $2\frac{3}{4}$ ; foreleg from elbow to end of longest toe nail  $4\frac{5}{8}$ . Hindleg from true knee to longest nail  $7\frac{1}{2}$ ; Planta from heel to long toe-nail  $2\frac{7}{8}$ ; heel to knee  $4\frac{1}{4}$ ; scut only  $1\frac{1}{8}$ ; scut and hair  $2\frac{1}{8}$ ; weight  $5\frac{1}{2}$  lbs. The female is 19 inches long and  $5\frac{1}{4}$  lbs. Both have a girth behind the shoulder of 12 inches: but the female's tail is the longer, being 2 inches, or 3 with the fur. Her other proportions are almost identical with the male's. Compared with the common species, which lies beside them as I write, these animals are conspicuously of darker hue and heavier make, but not larger. They have heavier heads, much shorter ears, smaller eyes, shorter tails, limbs shorter, stronger and less unequal—in that respect like a rabbit—and, lastly, their mystacial tufts are much less, and their fur much harsher. Looking closer into their structure it is observable that the profile of the head is less curved in the Hispid than in the common species, the nails somewhat larger, and the digits slightly different in gradation, the thumb in particular being less withdrawn, and the little finger more so, from the front, in Hispidus. But the nails have no peculiarity of conformation, and so far from being "very acute," they are very blunt and worn. The nose and lips agree precisely with those of the common species: but the eye is conspicuously smaller, and placed less backwards, or midway between the snout and ears. The ears both in male and female considerably exceed one half of the length of the head, and are broader as well as shorter than in *L. Ruficaudatus* or *Timidus*; and it is remarkable that the tail in the male is shorter than in the female—in both more so than in *Timidus*. The teats are six, two pectoral, and four ventral, just as in *L. Ruficaudatus*, and the skulls and teeth of the two species are framed upon precisely the same model, general and particular.—*Beng. As. Soc. Jour. No. CLXXIX. June, 1847.*

(969) *LEPUS PEGUENSIS*. Blyth, Is very similar to the *L. ruficaudatus*, Is. Geoffroy, of Bengal, Assam and an upper India, but at once distinguished by having the tail black above, as in the generality of the genus. Upper parts same colour as Bengal hare, but the belly abruptly white.

(970) *LEPUS RUFICAUDATUS*. Common all over Northern India.

(971) *LEPUS TYTLERI* seems the same hare as *T. ruficaudatus*.

(972) *LEPUS SINENSIS*? Captain Phayre,

## LINSEED.

imperfect skin of a Hare "from the east side of the range of mountains dividing Arakan from the valley of the Irawaddi, where the S. W. monsoon is much modified." It would appear to be identical with *Lepus sinensis*, Gray, of Hardwicke's 'Illustrations of Indian Zoology,' known only by that figure. The skull closely resembles that of *Lepus ruficaudatus*, Is. Geoff. (the common Bengal Hare; and so far as could be judged from what remained of the skin, the ears having been destroyed), the general structure would appear to be quite similar, but the colouring is remarkably different; being a mixture of deep tawny or rufo-fulvous with much black on the upper parts, and the under parts, whitish. The paws are black underneath, mingled with some tawny along the lower surface of the tarsus; the latter being almost pure white externally, and thus forming a remarkable and striking contrast with the hue of the lower surface. Tail black above and at the tip, whitish below towards its base. On the sides towards the belly the fur much resembles both in colour and texture that of the entire upper parts of *L. ruficaudatus*; but on the back the fulvous hue is very much deeper, and the admixture of black is much greater: the short soft underfur is deep buff or fulvous, whereas in *L. Ruficaudatus* the same is whitish or rather almost pure white.—*Beng. As. Soc. Jour. No. 4, of 1852, page 359.*

Hares are unknown in Arakan and in the Tenasserim provinces, also throughout the Malay-an peninsula and archipelago, with the exception of *Lepus Nigricollis*, F. Cuv. in Java, which has mostly probably been introduced from S. India or Ceylon, as it doubtless likewise has in the Mauritius; but we have met with several notices of Hares in the Hindo Chinese countries, even in Cochin China, the species being as yet undetermined.—*Beng. As. Soc. Jour.*

(973) LIENG-MAH, Burmese; Orange Tree.

(974) LIENG-MAH, Burmese; Lemon: (*Citrus lemonum*, &c.)

(975) LINSEED from *Facts for factories*, Bombay 1857. Four years ago (1853?) Bombay exported only 4,000 tons of seeds, whereas now (1857) it has reached 60,000 tons. Of these linseed forms about two-thirds.

### Price of seeds.

Linseed per cwt...	Rs. 5 to 6.
Rapeseed „ „ „ „ „ „	4½ to 5½.
Teelseed „ Candy of 5½ Cwt. „	20 to 27.
Copra (Stripped Coconut) Red	
per Candy of 5½ Cwt...	Rs. 54 to 60.
„ „ „ „ „ „	Black „ 55 to 60.

The loss in weight in cleaning linseed varies according to sample. On a good lot, the loss should not be over 5 per cent.

## LOMBOK.

usually about 4 per cent, in Kutch and Katty-war seed, it is very trifling.

On Khandeesh Teel seed, the loss is about 3 per cent.

Cleaning expenses come to about 2as. (3d) per cwt. but if done by machinery on a large scale, these should not exceed one anna (1½d) per cwt. and calculate another anna to cover weighing, carting &c.

In copra there is of course no loss in cleaning.

The red kind yields most oil, the black being used for food, is dearer.

Linseed has been known to cost less than four Rupees per cwt. and not very long since it was down to nearly that price and other seeds in proportion.

### Prices of oil in Bombay.

Cocoanut oil per maund of 28 lbs.	Rs. 3 10 0.
Castor " " " " "	2 15 0.
Gingelly oil (Sweet oil) " " " "	3 12 0.
Linseed " " " " "	3 0 0.

(976) *LOBIVANELLUS LEUCURUS*. This is found in India birds, the only Indian specimen previously recorded was obtained in Calcutta.

(977) *LOCUSTELLA RAYI*, Blyth, the British Grasshopper Warbler, would appear to be at Mhow not uncommon. A specimen has also been seen from the N. W. Himalaya.

(978) *LOLIUM ITALICUM*. Italian Rye Grass. Affords fine fodder for cattle: is a useful cold weather green crop, and is well worthy of extensive cultivation.

(979) *LOMBOK*. *The island of Lombok by K. Zollinger, Esquire.*

The princes of Mataram must be well acquainted with the number of the population of their island, since the manner of raising the taxes and regulating the military services, as well as the forced labour, obliges them to maintain a kind of census. The population of the island must amount to more than 400,000. I learnt this first from Mr. K., and afterwards from the Rajah himself, who at an audience asked, over how many persons Mr. Mayor had authority. When I answered over 500,000 the Rajah exclaimed in great surprise "that is then more than the population of my whole island." Finally, another chief informed me that the whole men capable of bearing arms amounted to 80,000 which multiplied by 5 gives 400,000 souls. If these data are correct, there are on Lombok exactly 4,000 persons on a square geographical mile. According to races and origin, the population of Lombok consists as follows:—

4 Europeans	5,000 Bugis.
1 European (coloured)	20,000 Balinese.
10 or 12 Chinese.	380,000 Sassaks.

One European lives at Piju, the rest at Ampanan. One Chinese is established as a trader, the rest are his servants, his coolies or those of the Europeans. The Bugis all reside upon the coasts

## LOTUS.

island. The population is divided amongst the different parts of the island as follows:—

north of the mountains,	40,000
in the mountains on the south	10,000
western half of the plain	220,000
eastern do.	135,000

This is an estimate made from the relative strength of population of those parts of Lombok visited personally. The data of the N. and of the S. were communicated.

The whole Balinese population reside at Mataram, and in the neighbouring parts, as at Ampanan, Karang, Assem &c. It is very prudent in the Balinese not to scatter themselves far in the country, because, in the event of an out-break they can be more easily collected together for defence than if they were settled in all parts of the island.

Small red fish (*iken mera*) are imported from Makassar.

Ivory, *Kayu pelet* and *Kayu Kamuning*, are imported by the Bugis from Sumatra and used for making the handles and sheaths of *Krises*, *Klewangs*, &c.

Exports to *Bima*, *Timor*, *Sumba*. Rice, *ding-ding*, oxen (very few).

Imports. Ponies (very few), fish, slaves (very few) sandal-wood (for China) tali ramie (thread of ramie) wax.

Of the government and the administration of the country it may be stated that the Rajah of Mataram is, by right of conquest, absolute sovereign of the island.

The Rajahs of Mataram are like their ancestors of Kawang, Assem and Beliling, members of the caste of Wasiyas. Although absolute monarchs, they consult nevertheless, of their own accord, in all important matters, the principal *gustis* and *idas* of the country, some of whom are entrusted with the execution of what is resolved upon. These men may be considered as the ministers of the Rajahs, if not *de jure et nomine*, at least *de facto*.—*Jour. Ind. Arch. Vol. V. No. 8, Aug. 1858.*

(980) *LOTUS*. The lotus is the most sacred flower among the Hindoos, it enters into all the ornaments of brass vessels used in the temples.

It is alluded to in the most popular poems, and the poets say, that the lotus was dyed by the blood of Siva, that flowed from the wound made by the arrow of Kama (Cupid)?

Yet marked I where the bolt of Cupid fell

It fell upon a little western flower—

Before, milk-white, now purple with Love's wound  
And maidens call it love-in-idleness.—

*Midsummer-Night's Dream. Act II.*

This flower is also considered an emblem of beauty; and in the *Retuavali*, or, the Neck-lace—a play written in the twelfth century, *Vasautaka* says to his lady love: My beloved *Sagarika*, thy countenance is as radiant as the

is the full-blown flower, and thy arms its graceful filaments.—*Wilson's Hindoo Theatre*, p. 296; *Chow Chow*, page 199.

(981) LUFFA. The Honorable W. Elliot sent two fruits of *Luffa Ægyptiaca*, grown in his garden, from seed brought by him from Egypt. This is one of the *Curcubitaceæ*. The Genus "Luffa" owes its name to the Arabic word for *Luffa Ægyptiaca*, viz. "louff" or "Loof," and is a remarkable kind of Gourd: when quite ripe, within, it has no pulp but is dry and filled with netted fibres, very much interwoven. It is used in Turkish baths as a scrubber. It is a useful product, and if cultivated would probably find ready sale.

*Luffa Ægyptiaca* is of easy culture, trained on a raised mound, similar to the snake gourd &c.—*M. E. J. R.*

### (982) LUFFA AMARA.

Hairy momordica, ENG.	Kereleh, PERS.
Luffe amere, FR.	Kerula, kurrella, INDIAN
Luffa bittere, GER.	and CASHM.
Kerula, BENG.	Sheti beera, TEL.

Every part of this plant is remarkably bitter,

the fruit is violently cathartic and emetic. The juice of the roasted young fruit is applied to the temples by the natives to cure headach. The ripe seeds either in infusion or substance are used by them to vomit and to purge—*Roxb.'s Fl. Ind. Vol. III*, p. 715.

(983) LUKUT, is at present the chief tin producing basin in the south of the Malayan Peninsula. It has a large population of Chinese, Malays and Binua, and its importance has induced the king of Salangor for some time to reside there. From Lukut, good Malay paths lead to the Langat on the one side, and Simujong on the other.—*Journ Ind. Arch. December 1850*. p. 754.

(984) LYLUT OOL QUDUR. *Arab.* The Night of power, occurs on the 27th night of the month Rumzan. Mahomedans sit up all night, burning frankincense-pastiles, repeating a particular prayer called "Nafil", reciting in praise of the Almighty, reading the Koran, and proclaiming the Azan. It is a period of great solemnity.—*Herkl.*

## M.

(985) MACAO. Sir John Davies states that it was about the middle of the 16th century that the Portuguese established themselves at this place. It seems that they had temporary shelter on shore.—*Davies, Chinese*.

(986) MACASSAR, from a few remarks made during the voyage of the *Himmaleh* in 1837, from the "Singapore Free Press" 1837, By the late G. Tradescant Lay, Esq.

The Macassar differs from the Bugis in having larger and more open features, as well as in the peculiar ruddiness that is mixed with the brown tincture of his skin. The hair is suffered to fall down and float loosely upon the shoulders, and has a red tinge oftentimes, by way of correspondence with the rest of the person. I have seen the truth of this circumstance questioned, because red hair and a dark complexion were thought incompatible with each other—an opinion that is not affected by this instance, for here the hair is not yellow nor orange, but its ends have a deep red hue, while the rest is black. The little boys and girls that you see running about in troops are often very handsome, while the lineaments of the latter are sometimes not only faultless in design, but they have withal a shade of thoughtfulness and melancholy, which is rightly esteemed to be the last touch and finishing stroke of personal beauty. These promises of future loveliness vanish before maturity, for the want, I suppose, of education, which, while it bestows un-

and perpetuate all the perfections of the body. I do not pretend to have a profound acquaintance with those branches of knowledge, that teach us to judge of the jewel by the shape of the casket; yet I cannot help thinking that the indications which I read upon the head and countenance of a Macassar, so often at variance with his present condition in the scale of morals and intellect, will hereafter unfold and explain themselves in a very delightful manner, when liberty and religion shall have cast their smiles upon him. That he is not deficient in head-piece is evinced by some productions of skill in the manufacture of gloves and baskets, where the workmanship for delicacy and fineness cannot be surpassed.

The first ascent of the barometer and the first descent of the thermometer in the afternoon is connected with a curious little fact in botany, the expansion of the flowers of the *Mirabilis jalapa*, which is for that reason here called the *Bunga Pakul Amput* or four o'clock plant. At 4 the barometer begins to rise, the thermometer to fall, the *Mirabilis* to open, as if by mutual understanding.

One of the prettiest plants I saw at Macassar was the *Damasonium indicum* or "telepo;" the petals are of delicate white, and the long calyx has its corners ornamented with a fringe gathered into a kind of flounce or furbelow. It is common in some of the floods

## MAHOMEDANS IN INDIA.

the beauty of its figure than by the singularity of the leaves, which bear some distant resemblance to the way-side plantain of Great Britain. In the same waters we find a species of Mimosa, with large yellow flowers and very long floating stem, covered between the joints with a spongy substance. But notwithstanding the large supply of moisture that is laid up in the spongy receptacles just mentioned, existence out of the water is not to be tolerated for a moment, for as soon as you attempt to lift up one end of the stem the leaves begin to fold, the nearest first and then the more distant in succession. When the plant is restored to its native element, the leaves once folded from such an injury never revive and expand, teaching us that this sensibility is something beyond the ordinary range of mechanical causes. A French experimentalist found some nervous matter in the sensitive Mimosa; I think this would have yielded a copious supply for examination.

At Macassar the *Indro* or Gomuto palm is very common; at Bonthain it is replaced by the Lontar palm, which often presents itself as you ascend the hills in large clumps. It is known here by the Hindu name of *Tala*, and yields a juice that is very refreshing when obtained in a pure vessel. But it is customary to catch it in an old bambu tube, which sets the process of fermentation at work, so that it is seldom free from an acid and, to one not used to it, a very disagreeable taste. In this state it is much relished by the natives, who pass the tampurong or shell to each other as if they drank more to please their palate than to allay their thirst. The stem is remarkable for its straightness, bare in the upper parts, but often covered with a loose texture of sheathing below, which is characteristic of the tree.—*Journ. Ind. Arch. Vol. VI. No. 10.*

(987) MADU-KAH, the Tamil name of a tree, the wood of which is yellow and very small; its grain is close and heavy: it is not of much use or value.—*Edye M. and C.*

(988) MAHOMEDANS IN INDIA are divided into the four great classes, Syed, Sheikh, Moghul and Pathan.

The Sheikhs are of three origins, the *Koreishee*, Mahomed's tribe; the *Siddegee*, Abou Bukr's tribe; and the *Faroojee* or Oomer's tribe.

The *Syeds* are all descendants of Mahomed through his daughter Fatimah.

The *Moghuls* are of two countries, the Iranee or Persian and Tooranee or Turkish.

The *Pathans* are said to be descended from some of the Greeks who settled in Affghanistan.

These classes may be and are often, indifferently of the Shiah or Sunnee sect of Mahomedanism.

There are other smaller sects and classes, as the Nowaets, the Ghair-Mehdi, Ishmaelee, Lub-

## MAHOMEDANS IN INDIA.

Mahomedanism comprises five divine commands,

1st.—Kulmah parhna, or confession of faith.

2d.—Numaz karna, or prayers.

3rd.—Roza rukhna, or fasting.

4th.—Zukat dayna, or alms-giving.

5th.—Mukkay ka huj karna, or pilgrimage to Mecca.

### *Mahomedan Saints of India.*

(989) *Abdool-qadir* surnamed Gows-ool-Azum the great contemplative, born at Jal, near Bagdad, A. H. 471 (A. D. 1078-79). He was endowed with great virtue and with the gift of miracles, had many disciples, and is still much revered. He is called Sheikh, but was a *Syed*, i. e. of the race of Hosein, and died in A. H. 571 (A. D. 1175), aged ninety-seven years. Where he died or was buried does not appear.

(990) *Sooltan Surwur*, at Balooch, four coss from Mooltan. He was distinguished for piety and purity of manners, and died as a martyr with his brother, fighting against a troop of idolators, and was buried with his wife (who died of grief) and his son, in the same tomb. Several miracles are related as having happened at his tomb. A camel's leg, when broken, was forthwith made whole; the blind, the leprous, the impotent were cured. (Araesh-e-Muhfil.)

(991) *Shah Shams ood Deen, Dariai*, at Depaldal in Lahore. He is stated to have had even a pious Hindoo among his disciples. The latter having expressed a wish to go and bathe in the Ganges, the saint directed him to shut his eyes, when lo! the Hindoo found himself among his relations and friends on that sacred stream, in which (as he supposed) he bathed with them. On opening his eyes again, he straightway found himself beside his spiritual guide in Lahore. His tomb is guarded by Hindoos, who will not resign their posts to the Moosulmans. It is also related that some carpenters having proceeded to cut down a tree which grew near his tomb, split it into many pieces for use. Suddenly a dreadful voice was heard; the earth shook, and the trunk of the tree arose of itself; the workmen fled terrified, and the tree did not fail to resume its flourishing condition.

(992) *Qootoob Sahib, or Qootoob ood Deen*, near Delhi. He lies buried at Qootoob, a town near Delhi named after him, in which the late Shah Alum and many members of the royal family of Delhi are buried. His tomb is much frequented by pilgrims, he being one of the most renowned and venerated of the Moosulman saints.

(993) *Sheikh Buha ood Deen, Zakaria*, Born at Cotcaror in Mooltan. He was a great traveller, having it is said, overrun Persia and Turkey, and a disciple for some time of Shihab ood Deen Sohurmurdee at Bagdad. He died on the 7th *Safur*, A. H. 665 (A. D. 7th September 1266).

(994) *Furreed ood-Deen*, Born at Ghanawal near Mooltan. He was so holy, that by his look clouds of earth were converted into lumps of sugar. He was therefore surnamed Shukur-gunj, which means in Persia the treasury of sugar.

(995) *Sheikh Shureef boo Ali Qulundur*, Born at Paniput, a town thirty coss north-west of Dehli, to which capital he came at forty years of age, and became a disciple of Qoottoob-ood-Deen. He devoted himself for twenty years to external sciences; after which he threw all his books into the Jumna, and began to travel for religious instruction. In Asia Minor he profited greatly by the society of Shams Tubreez and Mowluwee Room. He then returned home, lived retired and worked miracles, and is said to have died A. H. 724 (A.D. 1323-24.)

(996) *Shah Nizam ood Deen Owleea*, By some supposed to have been born at Gazna, A. H. 630 (A. D. 1622-3), and by others in A. H. 634 (A. D. 1236) at Badaam, a town in the province of Delhi where he lived. He died A. H. 725 (A. D. 1325); and was buried near Delhi, hard by the tomb of Qoottoob ood Deen. Through his great piety he was considered one of the most eminent saints of Hindoostan.

(997) *Kubeer*. A celebrated Hindoo Unitarian, equally revered by Hindoos and Moosulmans, founder of the sect called Kubeer Punthee or Nanuk Punthee, from which Nanuk, founder of the Sikhs, borrowed the religious notions which he propagated with the greatest success.

(998) *Baba Lal*. A Durvesh (and likewise a Hindoo) who dwelt at Dhianpoor in the province of Lahore, the founder of a sect called Baba Laees. He held frequent conversations on the subject of religion with Dara Shikoh, eldest son of Shah Juhan, and brother of Aurungzebe, which have been published in a Persian work by Chundurbhan Shah Juhanee.

(999) *Shah Dola*, Died in the seventeenth year of the reign of Alumgeer, at first a slave of Kumayandar Siolkoti in Lahore. But he seems afterwards to have attained great affluence as well as fame; for having settled at Ch'hottee Goojrat (little Guzerat), he built tanks, dug wells, founded mosques, and bridges, and embellished the city. And no wonder; for though his contemporaries came to visit him from far and near, and made him presents of gold, money, and other objects, he returned to each three or four-fold more than he received. His generosity was such, that had he been contemporary with Hatim Tai, no one would have mentioned the name of that hero.

(1000) *Syed Shah Zoohoor*, Distinguished by his wisdom, piety, and austerity of life. He built a small monastery of earth at Allahabad, which still remains. He was celebrated for his miracles, and by his prayers the most frightful

of which an instance is given in respect to the case of the governor of Allahabad, Nuwab Oomdut ool Moolk Ameer Khan. This saint (Zoohoor) boasted of having lived three hundred years.

(1001) *Sheikh Mohummud Ali Hazin Gillanee*. His tomb is at Buxar, where he died in A. H. 1180 (A.D. 1766-7), distinguished for his science, learning, and literary talents. He wrote in both prose and verse with equal skill.—*Herkl. p. 432.*

(1002) MAILAH, the Tamil name of a tree which grows to about twelve feet high, and twelve inches in diameter. It is generally curved, and is used in boat work. It produces a fruit which the wild pea-fowl feed on; and is to be found in the forests of Malabar, and also in Ceylon.—*Edye, M. and C.*

(1003) MALABAR POINT, BOMBAY. Here are the ruins of a very ancient black stone temple, and many fragments strewn about with a variety of images sculptured on them. Below the point among the rocks, there is a cleft well known to the natives, and esteemed very sacred.—*Chow Chow, page 60 and 61.*

It is here we believe, where the believing hindu, obtains regeneration or a second birth: He comes to the spot and deposits all his clothing, then passing through the aperture he is supposed to be born again, and ablution in the tank and gifts to the priests completes the washing away of his sins.

(1004) MALABAR COAST. Along this coast, cocoanut day, is one of the great feasts at every seaport town. It occurs in August, and is supposed to mark the termination of the rainy season, the date when the navigation of the sea is open, and when the Hindoo trader may very safely trust his ships and goods to the ocean. At Bombay, the natives clad in their holiday attire, go in procession from their houses in the town to the seashore, preceded by bands of music. On the beach, numerous ceremonies are performed over a cocoanut, generally covered with gold and silver leaf, which is then cast into the sea as an offering by the principal person present. Every trader or boat-owner there makes a similar offering on his own account. Many of the lower classes of natives swim or wade in, to fish out the cocoanuts; and as during the scramble, some of them often receive severe knocks from the cocoanuts, which are thrown in by persons in the crowd, there is generally a good deal of laughter, noise and excitement.

'The first boat of the season' generally puts to sea directly after, gaily decorated with streamers. In former days, the chief civil functionary at the Company's factories, at such places as Tanna, Surat, and Broach, used to attend and sometimes cast in the first cocoanut; but this practice has been long since stopped by orders from the Court of Directors, and no servant of Government is now allowed to take any part in any such

## MALAY PENINSULA.

(1005) MALAY PENINSULA. The Malay Peninsula, if we give the term its widest application, is disengaged by the Gulf of Siam from the broad mass of the general Hindu Chinese Peninsula in about  $13^{\circ}30'$  N. L. Its length is so great compared with its breadth, being nearly as 10 to 1, that it may be described as an irregular zone stretching from that latitude (Lon.  $98^{\circ}$  . .  $100^{\circ}20'$  E.) through above 800 miles (Geo.) to within  $1^{\circ}14'$  of the Equator (Lon.  $104^{\circ}27'$  . .  $104^{\circ}17'$  E.) and dividing the sea of Bengal from that of China in their southern portions. Its base is a line extending from a point a little southwest of Bangkok to the mouth of the Tavoy river, at right angles to the direction of its northern half. Thence it stretches almost due southward for about  $5\frac{1}{2}$  degrees between the Bay of Bengal and the Gulf of Siam, at first gradually contracting its breadth from above  $2^{\circ}$ , that of the base, to  $1\frac{1}{2}^{\circ}$  in  $12^{\circ}$  N. L., where the eastern coast suddenly retires at Kwi Point for about 40 miles, thereby reducing the breadth to about  $1^{\circ}$ , which it retains with little variation to the latitude of  $9^{\circ}$ . Here it again abruptly expands on the east into the Gulf of Siam, this expansion coinciding with the commencement of the second or southern half of the Peninsula, which is very decidedly distinguished from the northern by a difference in form and direction. It is to this latter half that the name of the Malay Peninsula should perhaps be restricted, as it indeed seems often to be by writers. The northern half is properly a long isthmus, that of Kira, connecting the Peninsular Malaya, (as it is sometimes called,) with the Hindu Chinese region.

A slight deviation of  $2^{\circ}$  E. from this direction (or  $140^{\circ}$  of the circle) will give the sides of a parallelogram 82 geographical miles in breadth, extending 540 miles throughout its whole length, and including the maximum of land that can be embraced by a regular figure of four sides, or 44280 square miles. Nothing can better show the essential regularity of the Peninsular form, and the correctness of the direction indicated, than the fact that the bulging portions on the east and west sides are themselves very elongated, no where of greater breadth than 50 miles, while generally much less, and altogether occupy about 17,280 square miles. The surface of the Peninsula is thus about 61,560 square miles.

If to this the Isthmus, which has a superficies of about 21,600 miles, be added, the entire area of the Malay Peninsula, in its widest sense, will be about 83,000 square geographical miles.

The western coast of the Peninsula is remarkable for the great number of islets of various sizes which skirt it. A broad and almost uninterrupted belt of these extends along all the western side of the Isthmus, and is continued as far

## MALAY PENINSULA.

the Lankawi group contains only a few. The rest of the western coast and the greater part of the eastern are more thinly sprinkled with islands. But there are several extensive groups of islands, some of them remarkably bold and imposing, along the latter coast, such as the eastern Johore Archipelago, and the Redang islands. The concave southern coast half embraces the islands of Singapore, and an Archipelago of several hundreds of islets stretching to the S. E. by S., from the termination of the continent to Banka and Billiton, marks that the peninsular zone has not yet wholly sunk beneath the sea, and, expanding as it does to the west and blocking the extremity of the Straits, attests how nearly a junction with Sumatra has been accomplished.

Most of the bays, coves and creeks have been subsequently filled up by sediment, producing flat plains and mangrove swamps, through each of which wind the waters from the surrounding hills, collected in streams. The most advancing hill ranges are often seen extending like ribs across the flats, and projecting at the coast or around the margins of the plains.

The western coast of the isthmus is hilly, much and deeply indented, and acquires a peculiar character from the broad and continuous zone of islands, known as the Mergui Archipelago, to which we have already alluded. Most of the islands are bold, and one of them, St. Matthew, rises to the height of 3,000 feet. The isthmus itself is occupied by numerous high hill ranges, which have the same general southerly direction. Along the sea borders considerable tracts of flat alluvial land occur, the best known of which is the large plain of Tenasserim.

From Junk-Ceylon to the Langkawi group, the coasts of the mainland and islands, still exposed to the full force of the Bengal sea, are broken, and frequently rocky and precipitous. The high and perpendicular limestone rocks, with their deep excavations pillared with colossal stalactites, and with their summits crowned with dense forest, present the most magnificent scenery. As we proceed south the coast changes, the islands disappear, and on the mainland a broad wooded plain extends from the beach to a considerable distance inland, where mountains are seen stretching away to the southward. The island of Pinang is a bold mountain mass, rising in some of its northerly summits, to a height of nearly 3,000 feet, and contrasting nobly with the broad and beautiful plain which lies opposite to it on the mainland.—Page 87.

It is impossible to form any estimate of the average height of the interior. The only mountain whose height has been accurately measured is that of Pinang. The summits, of which heights have been most carefully ascertained; are respectively 2,922 and 2,410 (Belcher) feet above

## MALAY PENINSULA.

Peak) and Gunong Ledang (Mount Ophir) have been stated to be 5,705 feet (Low) and 5,693 feet (Newbold,) high, but no dependence can be placed on estimates which have not the foundation of even the rudest barometrical or trigonometrical observations, and which are probably considerably too high.—*Page 89.*

In the geological formation of those countries, the Malay Peninsula forms an important link in the chain of evidence. It is directly united not only geographically but geologically with the continental mass, and, through the islands to the south and Sumatra on the west, a connection with the rest of the Malayan Archipelago can be established.—*Page 90.*

The mountain zone of Sumatra, while it is parallel to the Peninsula, and repeats its plutonic rocks, is at the same time, almost united to Java, and, throughout its whole length, contains tracts of volcanic rocks, and volcanoes, several of which are still active.

The volcanic belt of Sumatra extends at least to Chittagong, thus following the plutonic bands of the Hindu Chinese region through a large part of their course to the north.—*Page 91.*

Indications of coal have been found on the coast to the south of Junk-Ceylon, and a partial examination on different occasions during the year resulted in the discovery of coal at Tama, Tangong Bongbong and T. Patong, of which the most northerly is in lat. 8° N. and the most southerly in 7° 37' N. (Journ. Ind. Arch &c. vol. I. p.p. 145, 151, 353.) Traces were also observed about one degree farther south. It has not yet been found in layers sufficiently thick and pure to be wrought, being generally lapidified or pyritous. But, where pure, it is a highly bituminous jet, and superior to the products of the Indian coal fields. The existence of coal in the calcareous division of the Peninsula serves to shew that its geological features were analogous to, or identical with, those of the isthmus of Kra, before the era of the plutonic elevation of the zone.

We believe that the limestone has not been observed further south in the Peninsula than the Bunting Islands, which lie a few leagues to the north of Pinang. Opposite Pinang, and for some distance to the northward, sandstone appears to be the principal aqueous rock. It is associated with clays and shales. A similar formation probably existed and is still partially preserved, in Perak, but we have no account of the sedimentary rocks of that country, nor of the northern part of the next kingdom, Salangor. Of the southern part of Salangor and of Johore generally we can speak more positively from personal observations. The predominating sedimentary rocks in the last two degrees of the Peninsula are argillo micaceous and argillaceous

## MALAY PENINSULA.

ciated. The sandstones and common clays and shales, in some places predominate, as in Singapore, and some of the middle parts of Johore. The same rocks are found in the northern islands of the Johore Archipelago, but we are without any actual observations of the large portion of this Archipelago. In Banka the prevailing stratified rocks are clays and sandstones.

*Metals.*—The tendency to the production of metalliferous ores at and near the junction of plutonic and sedimentary rocks which has been observed in many countries, might have led us to anticipate a large share of metallic riches for the Peninsula. In reality it probably abounds in some ores far beyond conception.

Iron ores are every where found, and in the south they exist in vast profusion. In some places the strata have been completely saturated with iron, and here the bare surface of the ground, strewed with blackish scoriform gravel and blocks, presents a strange contrast to the exuberant vegetation of surrounding tracts, appearing as if it had been burned and blasted by subterranean fires. Much of the ordinary forms of ironmasked rocks, which are so common and so little regarded for their metallic contents that in Singapore they are used to macadamize the roads, contain often nearly 60 per cent. of pure metal.

The whole length and breadth of the Peninsula, there can be little doubt, abounds in tin ore. The uniformity, we might almost say unity, of its plutonic character, warrants the inference that ores found plentifully in many different and distant localities where they have been sought for, exist also in the intermediate tracts which have not yet been examined. At the two extremities of the Peninsular zone of elevation, Junk Ceylon and Banka, tin sand is diffused in such quantity that its collection has never had any other limit than the number of persons employed in it. In Junk-Ceylon and Phunga under a barbarous government, about 13,000 piculs are annually dug out of the soil. In Banka, under a European government, but without any improvement on the usual Chinese modes of excavating, washing and smelting, the production has increased from 25,000 piculs in 1812 when it was a British possession, to 60,000 piculs.—*Dr. Epp, Schilderingen aus Ostindiens Archipelago, p. 83.*

At numerous intermediate localities throughout the Peninsula tin is obtained; and when we consider the despotic, rapacious and too often remorseless character of the native governments, the consequent failure of all attempts to introduce European or Chinese capital and system into the tin mining, and the robberies and massacres which from time to time terrify and scatter the little communities of needy Chinese in these hands it has remained, the wonder is that

ket. In the Siamese countries north of Kedah and in Kedah itself which has been so long in a state of anarchy, it is sparingly extracted. From Perak 9,000 piculs per annum were formerly exported, but the produce has now greatly diminished owing to the miserable state of the country. Salangor and adjacent inland states yield about 9000 piculs. The eastern countries from Kalantan to Pahang yield about 11,000 piculs. The present produce of the whole Peninsula including Sinkep and Linga, the only two islands of the Johore Archipelago where it is now sought for, is probably above 40,000 piculs. The produce for many years past has ranged between that quantity and 30,000, the Peninsular range, therefore, including Banka, yields upwards of 100,000 piculs, so that it equals or exceeds that of Cornwall (6,000 tons) and may be expected to increase steadily.

Seeing that tin is procured in all parts of the Peninsula where it is sought for, and in proportion to the enterprise and labour which are devoted to the search, we may consider the entire zone as a great magazine of tin. It is, in fact, incomparably the greatest on the globe. Johore might have seemed to offer an exception to the apparent universality of the distribution of oxide of tin, if its geological affinity to Banka, the fact of tin having from time to time been found in several places, and for many years having been got in considerable quantity in Malacca, had not afforded the strongest presumption that its want of inhabitants and government was the cause of its non-productiveness. The last eighteen months however have placed the matter beyond doubt, and given a striking proof at once of the metallic fertility of the country, and of the little attention which this branch of industry has hitherto met with in the British Settlements. In 1845 Malacca, an integral part of Johore and having the same geology as the rest of the country, produced about 450 piculs of tin. In the succeeding year the interest of some Chinese of capital was excited in the subject, and more vigorous and extensive operations were commenced. In 1846 above 1,400 piculs were procured, the greater part from 39 pits in one valley. In 1847 the produce appears to have been from 4,000 to 5,000 piculs. In 1848 it will probably rise to between 5,000 and 7,000 piculs, for the government title upon it for the year has been rented for the unprecedented sum of 8,190 Sp. Dollars, the revenue from this source having been in the two preceding years Sp. 1,020 and Sp. 3,345 respectively.

Nothing can better shew how entirely the metalliferous character of the Peninsula has escaped the mining enterprise of private European capitalists than the fact that in the island of Singapore, where we have a line of junction between plutonic and sedimentary rocks of above twenty

miles in length, where tin was found in former years in at least two localities, and where the same iron ore with which it is associated in Banka abounds both in the igneous and aqueous rocks, no interest has ever been awakened in the subject.

In the Peninsula and Banka, tin has hitherto been procured by digging pits in alluvial tracts where the ore is found, generally intermixed with quartz particles, in a state resembling sand varying from fine to coarse. In most cases it appears to be properly stream ore i. e. the fragments and particles of disintegrated rock that have been borne to lower levels by rain torrents and streams. We think however that there are both tin and gold pits in which the rock has been decomposed and disintegrated in situ, and a careful examination would probably prove that there are many such. The clays in our Peninsular vallies are not always alluvial, and in the higher part appear most often to mark the decomposition of the subjacent rock. In a recent excellent geological work by Professor Ansted (*Geology, Introductory, Descriptive and Practical*, vol. II. p. 281.) it is erroneously stated that in Banka the ores of tin are entirely obtained by sifting the gravel and sand of rivers. In Banka and the Peninsula the beds of streams are seldom restored to, save to obtain indications of the probable abundance of "tin sand" in the vicinity. One of the narrow vallies between the parallel ranges or branches of the low hills is selected, and, if tin be found, pits from 10 to 60 feet in depth are dug, and carried regularly up the valley, a new one being opened as soon as the last is exhausted. In this way the entire breadth of a valley is sometimes excavated by successive pits throughout a length of two or three miles, if the tin sand be found continuous.

In Malacca the tin sand is generally found at the bottom of a series of alluvial layers. This is also the case in Cornwall, where it appears to be attributed to diluvial action. In the Malacca vallies there is no evidence of diluvial action. The accumulation of the tin ore in the bottom of the valley may be explained, in some cases, by the decomposition of the rock and washing away of the clayey and lighter siliceous particles, the tin ore and associated quartz remaining by their gravity. In other cases it may probably be explained by the consideration that in the earliest ages of the vallies the disintegration must have been more rapid and the fall of the vallies greater. The torrents in rains would have a considerable impetus, and carry forward the disintegrated fragments of the rugged and naked ravines. In the course of time these would be smoothed into gentle slopes covered with vegetation, and the slopes of the bottoms of the vallies would gradually decrease as their mouth became choked with mud flats and sand banks, and the alluvial deposit spread back, raising the level of the vallies.

## MALAY PENINSULA.

We have dwelt at some length on tin because it is the principal natural production of the Peninsula, which derives importance economically from the fact of its being the greatest stanniferous tract in the world and which has never been sufficiently appreciated. We are able to state confidently that the geological conditions which seem to be necessary for the production of tin in this part of the world are found in the Peninsula as fully developed as in Banka. Both portions of the zone have been equally affected by, and have indeed originated in, one and the same igneous action, of which one of the phenomena has been the formation of tin ore. The existence of tin in Banka was unknown until 1709 when it was accidentally discovered. Now, its produce doubles that of the Peninsula, although the latter has a surface 18 times larger. The reason is not a mineralogical one. It is because in Banka the Chinese are stimulated, furthered and protected by a strong Government, which directly interests itself in their operations.

We have large specimens with ore adhering to and partially invested with quartz. We are not aware that it has ever been actually seen in the solid rock in the Peninsula, but in Banka it is found associated with iron ore in veins in the granite. A Dutch writer also describes whole layers as occurring in some mountains which consist partly of granite, but in the centre principally of layers of sandstone and quartz in which iron ore also appears. In the more purely granite mountains it seems to have been observed in quartz at the junction of the granite with the iron veined sandstone strata. In the Isthmus of Kra it has also been found at the junction of sandstone and granite. In Cornwall it appears to be dependent on granite. "Granite or its modification elvan, occurs near, or at all the localities where tin and copper ores so abound as to be worked and produce good mines."—*De la Beche*.

The finest one of Banka yields as much as 80 per cent of metal, the common sorts from 40 to 60. The quality of Peninsular ores has not been ascertained so carefully. We are not aware that more than 70 per cent has ever been obtained.

Gold is found in the Peninsula, but, whether from inferiority of enterprise or natural deficiency, not in such abundance as in those parts of the adjacent countries of Sumatra and Borneo where it is systematically dug for. The present annual produce is probably about 20,000 ounces. In all the larger specimens which we possess or have seen it is disseminated in small particles, and streaks in quartz. Like the tin ore it has not been seen in the undisintegrated rock.

Copper, silver and arsenic have been detected in Banka, but apparently in small quantities.

*Climate*.—The mean temperature of the Peninsula is probably about 80° at the level of the

## MALAY PENINSULA.

sea. In its general humidity it also approaches to uniformity, but dry and rainy weather are more distinctly separated in the northern countries than in the southern. The latter are not subject to the occasional violent rains and prolonged droughts which visit the former, and the former are not exposed to the frequent tracts of damp, foggy, rainy weather which are experienced in the latter.

During the N. E. monsoon, which ordinarily blows from November to March, the weather is generally settled in the Straits of Malacca, and N. and N. E. winds, prevail, particularly on the coast of the Peninsula, but are not of great strength save towards the northern end of the Straits. Breezes usually blow from the Peninsular shore at night. The equable character of this season is attributable to the monsoon being broken by the mountains of the Peninsula, which stretch transversely to its direction.

The S. W. monsoon, which prevails from April to October, blows against the northern part of the west coast of the Peninsula, which consequently, in some measure, participates in the rainy climate which characterises the eastern shore of the Bay of Bengal during this monsoon. Further south, it is broken by the mountain belt of Sumatra, so that, in the Straits, land and sea breezes generally prevail in the vicinity of the coasts, and an equable climate is experienced. The Sumatra sides of the Straits, and the southern portion of the Peninsula, at night are exposed to occasional sudden squalls from the S. W. accompanied by lightning and heavy rains, called Sumatrans. Northwesters are also experienced, but more rarely. They occur chiefly in the northern part of the Straits as far as the Arroas, but sometimes blow right through them to the Carimons. During this monsoon the east coast of the Peninsula, having a leeward exposure, and being, for the greater part of its length, protected by the double wall of the Sumatran and Peninsular ranges, is perfectly sheltered, and dry weather prevails.—*Journ. of the Indi. Archipelago*, Vol. II, February, 1848.

*Ethnology*.—The annals of several ancient Malay states point to Palémbang as the original land of the Malays. They afford various indications of a close connection between it and Java, and mention Java invasions and settlements long anterior to the modern conquest of Palémbang by Majaphit. From their concurrent tenor, it appears that the royal dynasties of Menangkabau, Malacca and other states, traced their descent from Palémbang. It may be inferred that it was in Palémbang that the Malay race and language received their earliest and deepest impressions from Hindu and Javan influences and that the Indian monarchical form of Government was first engrafted on the Native Sumatran institutions, which are of a mixed patriarchal and oligarchical form. It is even probable that Palémbang

was closely connected with the Southern extremity of the Peninsula long before the foundation of the modern colony of Singapore. The remnant of the ancient vocabulary of Johore small as it is, contains some words only found elsewhere in Upper Palembang and others of Sundan and Javan affinity, which may also have been immediately observed through Palembang.

In an account of the wild tribes inhabiting the Malayan Peninsula, Sumatra and a few neighbouring Islands, by the Rev. P. Faver, Apostolic Missionary, Malacca, these wild tribes are divided into three principal classes, which are subdivided into many others. The first of these divisions includes the Battas, who are said to inhabit the interior of Sumatra and a few neighbouring islands. The second is that of the Semangs, who are found in the forests of Kedah, Tringanu, Perak and Salangor. Under the third head are comprised many tribes, known under the ordinary term of Jakuns, which inhabit the south part of the Peninsula from about Salangor on the west coast and Kemaman on the east, and extending nearly as far as Singapore. All these various wild tribes are ordinarily classed under the general and expressive appellations of Orang Binua, which signifies, men of the soil; this will be the expression I will use when speaking of these tribes generally and without intending to refer to any one in particular.—*Journ. of the Ind. Arch. Vol. II. No. 5. May, 1848, page 237, et sequent.*

*Binuas.*—Among the Binuas whom I have interrogated on the matter, many answered that the Malays were descendants in great part from them, who were, without any doubt, the first inhabitants of the land.—*Page, 238.*

*Jakuns of Johore.* This is a fine race of men many of them are taller than those of Malacca, their face is expressive and well characterized and the expression of the eyes in many of them is a little serene.

It is stated by the Binuas, and admitted by the Malays, that before the Malay Peninsula had the name of Malacca, it was inhabited by the Binuas. In course of time, the early Arab trading vessels brought over priests from Arabia, who made a number of converts to Islam: those of the Binuas that declined to abjure the customs of their forefathers, in consequence of the persecutions to which they were exposed, fled to the fastnesses of the interior, where they have since continued in a savage state.

I am therefore inclined to be of the opinion which Lieut. Newbold appears to embrace, and I am induced the more readily to believe that the Binuas, and chiefly the Battas of Sumatra and the Semangs of the north of the Peninsula are the savage people whom Herodotus has spoken of, as inhabitants of the eastern countries of India, producing gold; and I dare say with the same author, that it is scarcely possible that the father of history intended to speak

of any other Indian people; for he would have spoken of such clearly and fluently; since all the other parts of India to the Archipelago were very well known to that historian, whilst he on the contrary speaks of the tribes he describes, only in rather an obscure style, and as "having received an account of them from some adventurous traders who having sailed from the shores of the Red Sea or the banks of the Euphrates, coasting the shore of India to the Archipelago: and who returned to their native lands laden with the gold dust, ivory and spices of the east."

The Jakuns of Johore, are a fine race of men; many of them are taller than those of Malacca; the face also expressive and well characterized, and the expression of the eyes in many of them is a little severe; I have already observed that their nose does not recede at the upper part, neither is it so flat or so broad at its base, as this feature in the Chinese, Cochin Chinese and pure Malay. A thing in which the Jakuns (only those of the Menangkabau States) are truly skilled, is the art of using the Sumpitan and poisoned arrows; as I will have occasion to mention when speaking of their weapons. When the durian season is come, a good number of Jakun families leave their house, men, women and children repairing to places where durian trees are found. They then again clean the ground in order to find more easily the fruit, which falls when ripe, and, dwelling in the small houses of leaves, prepare themselves to enjoy the treat which nature presents to them. For six weeks or two months they eat nothing but durians. When the season is over, the place is abandoned until the next year. One of their most prized dishes is a honey-comb, and let it be said with due respect to the opinion of our European cooks, the time when the honey is in the comb is not, amongst these epicures of nature, considered the proper moment to take the hive; but they wait until the small bees are well formed in the cells, and a few days before they are ready to fly away the honey comb is taken with great care, and, wrapped up in a plantain leaf, is put upon the fire for a few minutes, and then wax, and animals are devoured together, and considered as an uncommon treat. The Jakuns chew betel leaf together with the areca-nut and gambier, but for the want of the betel leaf, they use the leaf of a tree called Kassi. Tobacco, when it can be had, is much used, even by women and children, in chewing and smoking. The Jakuns of Malacca, and those of Johore have no other arms than spears and parangs; very few use the sumpitan, and they are entirely unacquainted with the use of poisoned arrows.—Vol. I. p. 272. The Jakun's spears consist of an iron blade of about one foot long and one inch broad in the middle, attached to a thick rudely worked shaft about five or six feet long, and sharp at the inferior extremity, in

## MALAY PENINSULA.

order to enter easily into the ground ; for before they enter a house they strike the end of the spear into the ground, where it remains until they go away. This is also the custom of the Johore Binua. It is scarcely possible to meet a single Jakun without his spear, which is both a stick to walk with, and an offensive or defensive weapon as the occasion requires. The parang is an iron blade of about one foot long, and two or three inches broad with a haft like that of a large knife ; they use it to cut trees employed in the building of their houses ; and to cut branches to open a passage when journeying in the thick jungle : it is also used as a defensive weapon against wild beasts. I know a Jakun who being attacked by a tiger, defended himself with a parang (the only weapon he had with him at the time). Nearly half an hour was spent in this singular combat : the Jakun lost an eye and was seriously wounded in the head ; but the royal beast paid the forfeit with his life. The Jakuns of the Menangkabau States use the parang, the sumpitan with poisoned arrows, and a few of them the spear. The sumpitan is a small bamboo of the size of the index finger, from six to ten feet long with a head as large as a fowl's egg, this piece of bamboo is inserted until the head fits into a larger one of the same length. The arrows are very slight slips of wood the thickness of a knitting-needle, and from eight to ten inches long terminating in a fine point, coated with poison for the space of an inch or so ; at the other extremity of the arrows, is placed a cone of white wood, cut in such a way that it may just fill the tube of the sumpitan to receive all the impulse of the air, and this cone also aids in directing the arrow ; this is propelled by collecting air in the lungs, and strongly emitting it into the head of the sumpitan partly inserted into the mouth of the projector. The range, to take proper effect, is about seventy or eighty feet ; some can reach one hundred and forty or fifty feet ; but then there will be little chance of being dangerously wounded. The timiang or sumpitan used by the Mintira and other Burman tribes is described in *Journal Ind. Arch.* Vol. I. p. 272. A principal defect of the weapon is that, from the excessive lightness of the darts or arrows, a puff of wind affects their direction.

There is a tradition on the origin of some tribes of Jakuns, called Orang Laut, (men of the sea) because they live ordinarily in boats upon the sea on the shore. It is related in the following way by Newbold Vol. II. p. 4. II.

"Dattu Klambu, a man of power in former days, employed a number of Jakuns in the building of a palace. He had an only daughter, who, once upon a time observing the primitive costume of some of her father's workmen, was seized with an uncontrollable fit of merriment. Whereupon, the irritated Jakuns commenced

## MALAY AMOKS.

the incantation "chinderweye," and pursued their way to the forest, followed by the spell bound princess. Dattu Klambu despatched messengers to bring back his daughter, but she refused to return, and eventually became the spouse of one of the Jakun chiefs. Dattu Klambu, on receiving intelligence of this occurrence, dissembled his resentment, and invited the whole tribe to a sumptuous entertainment, on pretence of celebrating the nuptials. In the midst of the feast he fired the palace, in which the revels were carried on, and the whole of Jakuns except a man and woman perished in the flames. These two Jakuns fled to the sea-shore, and from them sprang the Orang Laut, who, not daring to return into the interior, have ever since confined themselves to the coasts and islets."

This tradition related by Jakuns is entirely different from another entertained by the Orang Laut themselves on the same subject, for, they say, that their first parents were a white alligator and a porpoise. *Ib.* p. 422.—*The Journ. of the Indi. Arch.* Vol. II. No. 5, May 1848, page 272.

(1006) MALAY AMOKS. We insert the following remarks, extracted from an official Medical Report on Singapore by Dr. Oxley. They are of very great practical value. The importance of the diffusion of correct views respecting it cannot be overrated.

The character of the unsophisticated Malay is remarkable for its simplicity and honesty ; having no artificial wants they are satisfied and content with what would be considered positive destitution by a Chinese, they are consequently apathetic and inactive, and will not for any amount offered to them, labour beyond their usual habits, or customary routine ; they have little of any speculative turn ; they have a regard for truth and may generally be depended upon in their statements. What has so often been written of their revengeful spirit is much exaggerated, polite in the extreme according to their own ideas, they never indulge in abuse one towards the other, the only reply to any deviation from this rule is the Kriss, for which they will watch their opportunity and most certainly not afford their adversary any advantage it is in their power to deprive him of. This is their code of honor, and being fully aware of it amongst themselves, provocation is seldom given, and satisfaction as seldom required. When goaded however to the necessity, they become perfectly reckless, and should discovery attend the deed they attempt no refutation but sell their lives at the utmost cost they can to the captors. Too often have I known the officers of Police compelled to shoot them on these occasions. Such is one species of "Amok," and how offenders of this description are to be dealt with, can admit of but little doubt, but there is another variety of the "Orang Beramok" vastly different, and by no means the least frequent,

which requires discrimination on the part of the Medical Jurist, to prevent irresponsible persons suffering the penalty of the injured Law. For instance a man sitting quietly amongst his friends and relatives will, without provocation, suddenly start up weapon in hand and slay all within his reach. I have known so many as eight killed and wounded by a very feeble individual in this manner. Next day when interrogated whether he was not sorry for the act he had committed, no one could be more contrite; when asked why then did you do it, the answer has invariably been "the Devil entered into me, my eyes were darkened, I did not know what I was about." I have received this same reply on at least twenty different occasions; on examination of these monomaniacs, I have generally found them labouring under some gastric disease, or troublesome ulcer, and these fearful ebullitions break out upon some exacerbation of the disorder. Those about them have generally told me that they appeared moping and melancholy a few days before the outbreak. It is certainly much to be deplored that monomania amongst the Malays, almost invariable takes this terrible form. The Bugis, whether from revenge or disease, are by far the most addicted to the "Amok" I should think  $\frac{3}{4}$ th of all the cases I have seen have been by persons of this nation.—*Journ. of the Indian Archipelago*, Vol. III, No. 8, August 1849, page from 532 to 533.

(1014) MAMMALIA of Ceylon by E. Blyth, Esq.—*Beng. As. Soc. Journ.* No. 2 of 1851, p. 153 to 185.

(1015) *Quadrumana*. Of five species (or very distinct races) of Monkey in Ceylon, one only is known to inhabit the neighbouring mainland, this is

(1016) *Presbytis Pariamus*, Elliot, Blyth. The small crested *Hinuman* of peninsular India, which is common in the Jaffna peninsula at the extreme north of the island, and probably to some distance farther south: but generally over the low northern half of Ceylon, we have in its place,

(1017) *Pr. Thersites*, Elliot, Blyth, a very similar race but nearly as large and powerful as *Pr. Entellus* of Bengal, and which is further distinguished from *Pr. Priamus* by having no abruptly rising compressed vertical crest, nor the radiating centre of hairs a little behind the brow seen

in the various other enteloid Monkeys. Its white beard and whiskers are also more conspicuously developed, and contrast strongly with the black face and dark body. According to Dr. Kelaart, they are respectively known as the *Maha* or ('great') Wanderoo, and the *Sadoo* (or 'white') Wanderoo. The *Pr. Cephalopterus* he indicates as the *Kaloo* (or 'black') Wanderoo, and the *Macacus sinicus* as the *Rilawa* of the Cinghalese.

Here it may be repeated that the name Wanderoo, as applied to *Pr. Cephalopterus* in particular, has been transferred by most writers to a widely different monkey of merely somewhat similar colourings,—the *Macacus sinicus*, which inhabits Travancore and Cochin, but has not been observed wild in Ceylon.

Mr. Layard states that *Pr. Cephalopterus* is "the common black monkey of the maritime provinces, very common also in the Kandyan districts. About Trincomali it is replaced by *Pr. Thersites*, and in the Jaffna peninsula by *Pr. Priamus*, which last is particularly abundant about Point Pedro." According to a letter since received from Dr. Kelaart, *Pr. Priamus* would seem also to inhabit the hilly country about Kandy. Dr. Kelaart, however, presented the Bengal Society with a fine adult male of the mountain or Kandyan representative of *Pr. Cephalopterus* from Newera Elia; and it is quite as different from the small animal of the coast as *Pr. Thersites* is from *Pr. Priamus*. General aspect the same but considerably larger and more powerful, with a much longer and very full coat, the piles on the sides measuring 4 to 5 in. long; In this it resembles the other mountain species of the genus, as the Himalayan Lungur, *Pr. Schistaceus*, Hodgson, a very strongly marked race (for habits of which vide J. A. S. XIII, 472,) and in a less degree *Pr. Johnii* of the Nilgiris. Colour nearly uniform greyish brown-black, with contrasting long white whiskers; the brows, hairs on cheeks, and those on the hands and feet, are deep black; there are traces of a paler tinge just perceptible on the occiput and about the croup; and the terminal three-fourths of the tail are grey. Entire length of hand 5 inch, and of foot  $6\frac{1}{2}$  inch. It is probable that this mountain animal varies in colour like *Pr. Cephalopterus* of the coast, to black, grey, grizzled, or light rufous brown; but all we have seen of the latter race have had the asbescent hue of the croup strongly contrasting, much more so than in *Pr. Johnii* of the Nilgiris, and the head generally brown as in the latter species, contrasting (though less so than in *Pr. Johnii*) with the black of the body (vide J. A. S. XVI, 1271). Should it be deemed worthy of a name, it might be designated *Pr. Ursinus*. At Newera Elia and scattered over the colder parts of the Island, is a species of very large monkey of a dark colour: some of those I saw were much bigger than the Wan-

## MAMMALIA OF CEYLON.

dura, and one that passed some distance before me, when resting on all four feet, looked so like a Ceylon Bear" (*Ursus labiatus*), "that I nearly took him for one." Forbes's "Eleven years in Ceylon." II, 144. In a letter from Dr Kelaart, he remarks that he has now several specimens of this monkey, one procured within 20 miles of Kandy. "Not one of them has the grey croup of *Pr. Cephalopterus*, and the hairs of the hands and feet are, in all, jet black. The ferruginous tinge of the hairs of the head and the grey of the occipital are present in all. The arms, too, are shorter than in *Pr. Cephalopterus* of the low country so that we may now consider this animal as distinct and confined to the mountainous regions of Ceylon—only in the Newera Elia specimens, the fur is longer and the tail more albescent."

Other species nearly affined in all but colour to *Pr. Cephalopterus* are *Pr. Pileatus*, Blyth, from the Tippera, Sylhet, and Khasya hills, and *Pr. Maurus*, (L.), from Java. In fact most of the black and rufous species of *Presbytis* are very closely affined, and several that are undoubtedly distinct are only separable apart by what might be considered trivial and insufficient distinctions. Another quadrumanous inhabitant of Ceylon, is the

(1018) *Stenopes Gracilis*, which is also found on the Coromandel coast.

(1019) *Cheiroptera*. The two common frugivorous Bats of India generally, *Pteropus Edulis* (vel *Edwardii* &c.), and *Cynopterus Marginatus*, are equally abundant in Ceylon. Dr. Kelaart sends a third, which is probably

(1020) *Pt. Leschenaultii*, *Dumeril*, though not completely according with the description. This small *Roussette* (or 'Flying Fox') measures about 6 inches from muzzle to tail-tip, the tail being about  $\frac{3}{8}$  inch and having its basal third invested by the interfemoral membrane. Expanse 19 or 20 inches; head  $1\frac{3}{4}$  inches; ears  $\frac{5}{8}$  inch; radius 3 inch; tibia  $1\frac{1}{2}$  inch; foot with claws 1 inch: upper-parts very thinly covered with short downy fur, of a dull brown colour; lower parts rather more densely covered with much paler brown fur. A specimen procured by Mr. Elliot somewhere on the Coromandel coast appears to be of the same species; but has the upper parts much more fully covered with brown fur, darkest upon the crown, and a whitish collar round the lower part of the neck. The hair on the sides of the neck, is longish and directed forward. Length of Radius  $3\frac{1}{2}$  in. The difference partly depends, no doubt, on the season in which the specimens were obtained: and the only other frugivorous Bat known to inhabit India is *Pt. Dussumieri*, Is. Geoff. vide J. A. S. XII, 176.

(1021) *Taphozous Longimanus* (Hardwicki), is a species and genus added by Dr. Kelaart to the fauna of Ceylon.

(1022) *Taphozous Brevicaudus*, Blyth, J. A. S.

## MAMMALIA OF CEYLON.

X. 970, is another species likely to occur as it was described from a specimen procured in Travancore.

(1023) *Megaderma Lyra*. Geoff. (or *M. Carnatica* Elliot, and *M. Schistacea*, Hodgson), appears to be common.

The species of *Rhinolophus* would seem to be numerous. Of true *Rhinolophus*, Mr. Waterhouse gives *Rhin. Insignis*, Horsfield with a mark of doubt against the specific name, from Ceylon, in his catalogue of Mammalia in the museum of Zoological Society (1838); and we have seen no true *Rhinolophus* from the peninsula of India, unless *Rh. Mitratus*, Blyth, (J. A. S. XIII, 483), from Chaibasa be deemed an exception. In a letter Dr. Kelaart informs us that he has since obtained a very large *Hipposideros*, and likewise a *Rhinolophus* as this genus is at present restricted. But of *Hipposideros*, Gray, there appear to be many species in Ceylon. Of the three noticed in Mr. Elliot's Catalogue of the Mammalia of the S. Mahratta country (*Madr. Journ.* X, 98), viz *H. Speoris*, *H. Murinus* and *H. Flavus* (vide J. A. S. XIII, 489), the first two are common; and *H. Ater*, Templeton, is a third described in J. A. S. XVII, 252. The last we have not seen; and Dr. Kelaart now sends two species additional to a specimen of *H. Murinus*. These are probably

(1024) *H. Vulgaris*, (Horsf.), apud Gray, of India and

(1025) *H. Pasillus*, (Tem.), of India, the specific name given with doubt by Mr. Waterhouse (*Catal-Zool-Soc-Mus*).

The first, though nearly affined to—is certainly not identical with—*Rh. vulgaris* apud Blyth, J. A. S. XIII, 488, from Arakan, length about 3 in. of which the tail is  $\frac{1}{8}$  in; expanse about 12 in. or nearly so; radius 2 in.; tibia  $\frac{7}{8}$  in.; ear-conch  $\frac{1}{2}$  in. The membrane surmounting the frontal pits exhibits three distinct small longitudinal ridges. Fur of the upper-parts pale greyish-brown at base, then dusky-brown which gives the prevailing hue of the surface, with very slight pale extreme tips. Lower-parts nearly uniform brown, with also slight horny tips.—Membranes dark. The other (*H. Ater*?) is smaller and possibly a variety only of *H. Murinus*, which (so far as can be traced in the dry skin) it resembles in structure. Colour whitish above, with blackish tips to the fur, the two colours being equally conspicuous; and below whitish brown. These Bats cannot be properly described unless when fresh or preserved in spirit.

The genera *Rhinopoma* and *Dysopus* have probably yet to be discovered in Ceylon. No doubt *Rh. Hardwickii* and *D. Pileatus* exist there.

Of ordinary Bats (*Vespertilioninae*), the

(1026) *Nyctcejus Heathii*, Horsfield, appears to be very common, as generally over the peninsula of India. In Bengal it is replaced by a smaller species of similar colouring. This is the *N. Heathii*, Horsfield P. Z. S. 1831, p. 113,

## MAMMALIA OF CEYLON.

length (of an adult male in spirit) 6 inch of which the tail measures  $3\frac{3}{8}$  inch; alar expanse  $16\frac{1}{2}$  inch; fore-arm  $2\frac{5}{8}$  inch; longest finger  $4\frac{1}{2}$  inch; tibia  $1\frac{1}{8}$  inch; foot with claws  $\frac{7}{8}$  inch. The difference of bulk and of size of the head, on comparison of this with the next species, exceeds that of the linear dimensions. The skull, also, with the teeth, is much larger in *N. Heathii* measuring  $1\frac{1}{8}$  inch in length, inclusive of the sagittal ridge and more protruding lower jaw; the upper canines project more than  $\frac{3}{16}$  inch from their long sockets. Hab. central and S. India and Ceylon.

(1027) *Nycticejus Luteus*, Blyth, *n. s.* length (of a large male)  $5\frac{3}{8}$  inch; of which the tail measures  $2\frac{1}{2}$  inch; expanse  $14\frac{3}{4}$  inch; fore-arm  $2\frac{1}{4}$  inch; longest finger  $3\frac{3}{4}$  inch; tibia  $1\frac{5}{8}$  inch; foot and claws  $\frac{1}{2}$  inch. The entire length of skull is barely 1 inch; inclusive of the greatly developed sagittal ridge. Hab. Bengal, Coromandel.

In structure both resemble *N. Belangeri* and both have the upper-parts when fresh of a very rich tawny or golden-brown colour, having a slight greenish cast; the lower parts fine yellow, more or less deep, and not unfrequently tinged with fulvous. By exposure to light the colours fade much in both species the rich yellow tinge gradually disappearing. *N. Belangeri*, (Tem.) is common to India generally and the Burmese and Malay countries, being in Ceylon equally abundant.

To these Dr. Kelaart adds another of about the same size, which was long ago forwarded from Chaibasa in Central India by Capt. S. R. Tickel. and may now be described as

(1028) *Nycticejus Tickeli*, Blyth, *n. s.* Length  $4\frac{1}{2}$  in. of which the tail measures  $2\frac{1}{8}$  in.; expanse 16 in.; length of fore-arm  $2\frac{3}{8}$  in.; of longest digit  $4\frac{1}{2}$  in.; tibia  $1\frac{5}{8}$  in.; foot with claws  $\frac{1}{2}$  in.; ears internally, from lowermost base  $\frac{5}{8}$  in.; and externally hairy for the basal half. Fur moderately long, soft, and straight, or a little wavy; of a pale fulvescent or whitish-fulvous colour, more or less tinged with maroon or vinous on the back: the membranes dusky, marked along the digits as in *Kerivoula Picta*, but the brighter colour spreading less upon the membrane, though the interfemoral is chiefly or wholly of this hue. There is a considerable growth of hair upon the basal half of the interfemoral membrane above, also along the tibia, and especially upon the toes: the face likewise is hairy around the eyes, and on the muzzle. Ears triangular and obtusely pointed: the tragus broad and semi-circular and suddenly narrowing at tip. Lastly, the dentition exhibits a peculiarity; this animal having a short, flat, obtusely trilobate or quadrilobate second pair of upper incisors, situate posteriorly to the usual large pair, and immediately behind the contact of each of the latter and the canine of the same side. This we have seen in no other species. Hab. Central

## MAMMALIA OF CEYLON.

India, Ceylon, and doubtless the intervening hilly country.

(1029) *Kerivoula Picta*, Gray;

*Vespertilio pictus*, Pallas (originally described from Ceylon); *V. Kervaulo* Boddaert.

*Kihavoula*, Cingh. (Kelaart),

Specimens sent dry and in spirit by Dr. Templeton and Mr. Layard are perfectly identical in species with one received from Java; and Dr. Cantor met with this species also at Pinang. Schinz gives it from Java, Sumatra, Borneo and, doubtfully, Ceylon. Mr. Layard says of it, "I have only met with this species about Colombo in any abundance, and I obtained one solitary specimen at Ambegamoa" Mr. Gray notices a *K. Sykesi* (we believe still undescribed), from "India, Calcutta;" this we do not know, but in Lower Bengal (where apparently very rare) and in central India, there is a fine species of nearly the same remarkable colouring, which is likely to be sometimes mistaken for *K. Picta*, though differing from it in many particulars. It appears to be *Vespertilio formosus* Hodgson, J. A. S. IV. p. 700, assigned by Mr. Gray to his *Kerivoula*, though improperly if it be the species here referred to, which accords in the number of its teeth with Mr. Hodgson's description, supposing that its exceedingly minute second upper præmolar was overlooked. This species and *K. Picta* and *Nycticejus Tickeli* present the same remarkable and beautiful style of colouring; but the dentition and other characters differ. (We have since received another and remarkably handsome large species of *Nycticejus*, with similar colouring of membranes, from the Khasya hills,—*N. ornatus*, Blyth,—a description of which will appear in a subsequent article.) The *Nycticejus* has the short and very broad muzzle, strongly developed sagittal, occipital, and parietal crests, and comparatively powerful teeth with the upper carnassiez adjoining the canine, which we observe in *N. Heathii* and the species affined to it; and there are two præmolars below, of which the second is the longer. *Vespertilio Formosus* (?) has three præmolars below, of which the medial (or that next to the *carnassiez*) is minute; and the upper carnassiez is widely separated from the canine, and in the interval are one developed præmolar, and posterior to this another which is excessively minute and liable to be overlooked: there are no ridges to the skull, or the middle one is barely traceable; the muzzle is comparatively narrow; and there are two upper incisors on each side of equal size: Chaffron a little concave. In *Kerivoula Picta* the chaffron is highly concave, the muzzle again much narrower, and there are two pairs of upper incisors of which the inner are longer, and so placed that on a direct front view they are alone visible, the second pair being concealed behind them; in *V. Formosus* (?) the four are equally visible on a front view. There are two præ-

## MAMMALIA OF CEYLON.

molars of equal size between the upper canine and the *Carnassiez* and two below of scarcely inferior size to the third or lower *carnassiez*. Lastly, the ears of *V. Formosus* (?) are not those of a *Kerivoula* (as exemplified by *K. Pieta*), but are deeply emarginated externally at one third of their length from the base, and above comparatively narrow and obtusely pointed: tragus also broader, shorter, and less attenuated at tip.

The only other Bat we have yet seen from Ceylon, is a minute species which appears to be extremely common throughout India, and is also met with at Singapore. We believe it to be *V. Coromandelicus*, F. Cuv., and to be identical with *V. Irretitus*, Cantor (*Ann-Mag N. H. IX*, 481,) from Chusan; and *V. Minutus*, Temminck, from the Cape of Good Hope, would seem to approximate, so far as can be judged from the brief description of Prof. Schinz. Size of the *Pipistrelle*, (Note. On comparison of British specimens of the *Pipistrelle* with an example in spirit sent by Mr. Hodgson from Nepal with the M.S. name *V. pallidi ventris*, we could discover no difference whatever. According to Schinz, the same species further inhabits Japan,) are on the average somewhat shorter in the fore-arm, which does not exceed  $1\frac{1}{2}$  in. in length; longest digit 2 to  $2\frac{1}{2}$  in.; expanse rarely exceeding  $7\frac{1}{2}$  in. (Dr. Cantor gives 8 in. as the expanse of his *V. irretitus*, but the other measurements sufficiently correspond). Total length  $2\frac{1}{2}$  in., of which the tail measures  $1\frac{1}{2}$  in.; ears broad, exceeding  $\frac{1}{4}$  in. in length; tragus  $\frac{1}{8}$  in., appearing lanceolate in the dry specimen, but in the fresh animal somewhat lunate, or a little curved forward and obtuse at tip. The fur is short, as compared with that of the *Pipistrelle*, and dingy fulvous-brown above at the surface, below paler and greyish fulvous; membranes dusky. The skull rather exceeds  $\frac{1}{2}$  in. long: the upper *carnassiez* is all but contiguous to the canine, and there is a minute præmolar situate internally and not visible externally; and two lower præmolars, of which the second or *carnassiez* is longer by about a third than the first. This Bat belongs to that large division of *SCOTOPHILUS*, Leach (apud Gray), the species of which have permanently two pairs of small upper incisors of about equal size: to these we prefer to restrict the name *SCOTOPHILUS* reserving *NYCTEJUS* for those in which the adults have only one large incisor on each side. Accordingly we term it (though somewhat doubtfully) *SCOTOPHILUS Coromandelicus*. This diminutive species is remarkable for the extreme velocity of its flight, as particularly shown darting about a room after being molested; and it is the most common of the small Bats about Calcutta. Mr. Hodgson did not meet with it in Nepal, and it possibly does not inhabit the sub-Himalayas. It is the No. 12 of Mr. Elliot's list in the *Madras Journal of Literature and Science*,

## MAMMALIA OF CEYLON.

(1030) *Carnivora*. Dr. Kelaart sent flat skins of what he considered to be two varieties of Jackals; but we regard them as mere individual variations of colour, such as are seen in all parts of India. No other wild canine animal has hitherto been discovered in the island.

(1031) *Viverridæ*, of these the Civet of Ceylon is probably not *Viverra zibetha*, L.; as supposed by Mr. Layard, but of a race procured by Mr. Walter Elliot from Travancore, and of which a specimen exists in the museum of the Zoological Society, referred to *V. zibetha* in Mr. Waterhouse's Catalogue of the mammalia in that collection (1838), No. 252. In that Catalogue it is marked "Sumatra, donor, Sir Stamford Raffles;" but we are the more inclined to suspect a mistake both as regards the donor and the habitat, from its being stated (formerly at least on the label of the specimen) to have been presented by the Duke of Northumberland. Both Mr. Elliot's Travancore specimen and that in the Zoological Society's museum exactly resemble the African *V. Civetta*, except that the dorsal mane ceases between the shoulders instead of being continued forward to between the ears.

(1032) *Viverricula Malaccensis*. (Gm.), and *Paradoxurus Typus*, F. Cuv., sent by Dr. Kelaart, as previously by Mr. Layard, are perfectly similar to Bengal specimens. There is also in the Island

(1033) *Paradoxurus Zeylonicus*. (Schreber), a very young example of which was formerly sent to the Society by Dr. Templeton, then of Colombo. This young animal is uniformly of the colour of the upper-parts of *Mustela vulgaris*, 'merely a little paler below, and shewing no decided trace of the longitudinal dorsal stripes. A living pair was afterwards presented to us by A. O. Brodie, Esq. of Putlam. These were then not fully grown, and were paler than the last, with the limbs darker, and the three longitudinal dorsal streaks distinct. The female died in this colouring, and is now preserved in the Society's museum; but the male still lives, and has become considerably deeper in his general hue. Of two specimens now sent from Newera Elia by Dr. Kelaart, one is again deeper-coloured than the living male, except its tail which is paler, and the dorsal stripes are inconspicuous though distinctly traceable: the other is much darker, considerably more so indeed than *Lutra vulgaris*, with remarkably handsome fur, and no trace of the dorsal streaks; the tail paler, with a subterminal yellowish white ring—exhibiting thus the tendency to partial albinism which is so often observable about the tail tip, and sometimes the feet and even the body, of animals of this genus, as especially the common *P. Typus*. We do not hesitate in considering all these varieties of colour in different specimens of *P. Zeylonicus* to have no special importance; but on present data it is probable that those which inhabit high

## MAMMALIA OF CEYLON.

up on the mountains (*P. montanus*, Kelaart,) have finer and darker-coloured fur than those of a lower region.

(1034) *Herpestes*. There are four species of Mongoose (*Herpestes*) in Ceylon:

(1035) *H. Vitticollis*, (Bennet), is not uncommon in the interior; and

(1036) *H. Griseus*, (Geoffroy), appears identical with the race of Bengal, the nose and paws of the only specimen we have seen being, however, considerably darker. This specimen was sent by Mr. Layard from the Jaffna peninsula; and he remarks that there is "another variety of Trincomali which accords exactly with the Indian animal." Dr. Kelaart states, in a recent communication. "I have now two other species of *Herpestes* besides the *H. Griseus* and *H. Vitticollis*,—one like *H. Auropunctatus*, Hodgson, but not it, is very like *H. Griseus*, except that the grey of the hair is in this fulvous or yellow (if new, *H. fulvescens*, mihi): the other is of a dark ruby red; tip of tails and feet black; ferruginous-red face; and as large as *H. Vitticollis*." The former of these is probably *H. Auropunctatus*; and the latter, we have little doubt, is a very distinct species formerly sent on loan by Mr. Elliot, who procured it in the south of India, but has not given it a name, so far as we are aware. His specimens, however, were smaller than adult *Vitticollis*, and more affined to *Griseus* in structure. The following notes were taken of them, and we may here characterize the species as

(1037) *Herpestes Elliotti*, Blyth. Entire length 26 inches of which the tail measures half: length of fore-limb, to end of claws,  $3\frac{1}{2}$  in; and of hind-foot with claws  $2\frac{1}{2}$  in. General colour as in *H. fuscus*, Waterhouse, of the Nilgiris, but the pale portion of the annulated hairs whiter,—the four limbs blackish above,—and the tail (which is less bushy than in *H. fuscus*) tipped with black for the terminal  $2\frac{1}{2}$  or  $3\frac{1}{2}$  in. In this specimen there was an appearance of a collar, from the greater development of the blackish portion of the hairs and of the whitish portion lower down, in those forming a sort of nuchal ring. Another specimen had the general cast of colour redder,—a maroon-red prevailing very bright on the four limbs above the black feet, and upon the tail where bordering on its black tip. Hab. S. India.

(1038) *Felidæ*. Of Cats, there are, in Ceylon, *F. Pardus* (vel leopardus) and its black variety *F. Viverrinus* and *F. Chaus*. *F. Tigris* and *F. Jubatus* are unknown: and *F. Bengalensis* (var *wagati*, Elliot), and *F. Rubiginosa*, Is. Geoffroy, both inhabitants of peninsular India, remain probably to be discovered.

(1039) *Mustelidæ*. The only Otter we have seen from the Island is *Lutra Nair*, F. Cuvier, which is not uncommon; and it is also the only species which we have seen from the peninsula of

## MAMMALIA OF CEYLON.

in Travancore and sent on loan by Mr. Elliot, may prove to be that of another. This specimen is remarkable for having the whole upper half of the head and body and of the basal moiety of the tail, covered only with the short and close downy fur common to the genus, with merely a very few scattered piles of the ordinary longer intermixed. The under half of the head and body and rest of the tail are clad as usual, precisely as in *L. Nair* and similarly coloured; but what is remarkable, is the abrupt and well defined straight line of demarcation separating the upper and lower halves of the animal, and passing immediately below the ear-coch. We suspect, however, (in fact feel satisfied,) that the individual was killed while changing its coat; but its size is still remarkable, being equal to that of the common Bengal Otter (*L. Chinensis*, Gray, vel *tarayensis*, Hodgson &c.) Nevertheless we consider it identical with *L. Nair*.

(1040) *Ursidæ*. The Bear of Ceylon is the *Ursus* (vel *Prochilus*) *Labiatus* of all India southward of the Himalaya, and which is peculiar to this country.

(1041) *Insectivora*. *Sorex* is the only genus as yet ascertained; but the discovery of *Tupia Elliotti*, Waterhouse (*Proc. Zool. Soc.* July 24th, 1849), in the eastern ghats of peninsular India, renders it likely that this genus also may have its representative in Ceylon. Perhaps, also, the Hedgehog of the Nilgiris (*Erinaceus Micropus*, Blyth, J. A. S. XV, 170), or other species of this genus, may inhabit the Island; the more especially as Dr. Kelaart remarks that there are two species of Hedgehog preserved in the Medical Officer's museum at Colombo, though whence brought is not known.

(1042) *Sorex Murinus*, L. (apud Gray), the common Indian Musk shrew, is mentioned both by Mr. Layard and Dr. Kelaart; and the latter gentleman has forwarded two mountain species for examination, both of which we consider to be new and undescribed.

(1043) *Sorex Montanus*, Kelaart, n. s. A typical *Sorex*, with dentition &c. as in *S. Murinus*. Total length 6 inches of which the tail measures  $2\frac{1}{4}$  inch. hind-foot, minus claws,  $\frac{5}{8}$  in. colour uniform dusky or dusky-slate, with the tips of the fur rufescent. Dr. Kelaart sent two specimens from Newera Elia, which, most decidedly, are of the same species; but one of these had a very powerful odour when fresh, and the other was inodorous.

(1044) *Sorex Macropus*, Blyth, n. s. General aspect of typical *Sorex* with colourless teeth and scattered long hairs on the tail; the ears scarcely visible beyond the fur; and the feet remarkably large. Length about  $6\frac{1}{2}$  in. of which the tail is  $2\frac{1}{4}$  in; hind-foot with claws nearly  $\frac{7}{8}$  in; the fore-foot  $\frac{1}{4}$  in. broad, with long and but slightly

## MAMMALIA OF CEYLON.

in length. Fur somewhat long and very soft, uniform blackish, very faintly tinged rufescent; the extreme tip of the tail dull white in the only specimen examined. Teeth small, the upper quasi-incisors shorter and less strongly hooked than in the typical *Sorex*, with the posterior spur large; the lower quasi-incisors serrated, showing two depressions, and therefore a row of three coronal points. Behind the upper false incisors a series of four small præmolars precedes the *canassiez*, the two medial being of equal size, the first rather large, and the fourth smaller; and below are the usual two (inclusive of the *canassiez*), as in the genus generally. Accordingly, this species cannot be brought satisfactorily under any of the subdivisions of *Sorex* yet instituted; and its very large feet, more especially, indicate that it should form a particular subdivision. Both this and the preceding species are found at Newera Elia and to 1000 feet below. (The shrews have very anomalous dentition; and we consider their quasi-incisors above and below to be *modified præmolars*. The upper canines appear to be wanting throughout the order, and the lower canines when present are generally small, the first præmolar above and sometimes below being magnified to assume the form and fulfil the function of canines (vide XIX p. 216). In the shrews no intermaxillary bones have been traced at any age and therefore the upper front teeth are decidedly not incisors, as they are generally termed: if canines, they would be an anomaly throughout the order; and extracted from the socket they have more the character of præmolars, exhibiting a second fang coalescent or imperfectly separated (i. e. originally distinct no doubt) proceeding from the posterior spur or cusp. The lower front teeth have also two coalescent fangs, shewing a broad and deep median groove on the inner side, and a similar but less extended groove on the outer. Thus, at least, in *S. Murinus*. It is not unlikely that in some of the other species (or subgeneric forms) the two fangs may be permanently separate.

In addition to *S. Murinus*, *S. Montanus* and *S. Macropus* in Ceylon, Dr. Kelaart writes that he has lately received two specimens of a large black Shrew double the size of the last which he also considers to be distinct and probably undescribed.

## RODENTIA.

(1045) *Sciuridae*. Of this family, Dr. Kelaart sends two species of Flying Squirrels. One is

(1046) *Pteromys Oral*, Tickell, found throughout the peninsula of India. The other is a magnificent

(1047) *Sciuropterus*, which possibly may be a fine adult of the species described as *Sc. Fuscocapillus*, Jerdon, Blyth, J. A. S. XVI, 867, from a younger and comparatively inferior specimen. We incline, however, to the opinion that it is distinct; and Dr. Kelaart terms it,

## MAMMALIA OF CEYLON.

(1048) *Sciuropterus Layardi*, Kelaart. Nearly allied to *Sc. Caniceps*, Gray, of the S. E. Himalaya, from which it differs in having the fur of its under-parts of a dull non-fulvescent white, the parachute membrane being margined with pure white fur, lengthened and conspicuous at the angle. Face grey, except the forehead which is rufous-brown, like the rest of the upper parts. A dusky spot on the nose. Whiskers long and black; and there is a tuft of long soft hairs below the ears and a smaller tuft before them. The ear-conch is  $\frac{3}{4}$  inch long posteriorly, ovate and somewhat narrow. Fur very dense, the basal three-fourths of the piles dusky, sinuous, and fine in texture; the tips coarser, and shining dull rufous-brown, forming the surface colour. Tail flat and broad, above nigrescent, and below deeper blackish except at tip. Feet greyish, with a faint rufous tinge on the hind only. Length about 2 ft., of which the tail with hair measures half; hind foot, from heel to tip of claws,  $2\frac{1}{2}$  in.; fore-foot to membrane,  $1\frac{1}{2}$  in. Hab. Mountains of Ceylon (Dimboola).

(1049) *Sciuri* of Ceylon, these are treated of in J. A. S. XVIII, 600 *et seq.* where five species are enumerated, to which Dr. Kelaart has now added

(1050) *Sc. Triliniatus* Waterhouse, (v *Delesserti*, Is. Geoffroy), identical with the race of the Nilgiris and Malabar. He has also favoured the Society with a fine example of

(1051) *Sc. Tennentii*, Layard, *loc cit.*, perfectly similar to that sent by Mr. Layard; and with a young specimen of

(1052) *Sc. Macrourus*, remarkable for having the terminal three-fourths of its tail unmixed white or slightly yellowish white. "The *Sc. Macrourus*," he remarks, "I have seen of various colours; some black: and I am inclined to think the *Sc. Tennentii* only a large variety of it *Sc. Macrourus*, even changes colour from brown to black," Mr. Layard, however, insists that "*Sc. Macrourus*, the common large Squirrel of our western coast, never intrudes on the haunts of *Sc. Tennentii*, nor is intermingled with it in its own locality." The two seem to hold, therefore, the same mutual relation as *Presbytis Thersites* and *Pr. Priamus*, or *Pr. Ursinus* and *Pr. Cephalopterus*. The rufous capped striped Squirrel noticed in a foot-note to J. A. S. XVIII. 602, Mr. Layard terms *Sc. Kelaarti*, Layard; but it does not appear sufficiently distinct from *Sc. Brodiei*. According to Mr. Layard, "*Sc. Tristriatus* is the common low country Squirrel" (of the island). "*Sc. Brodiei* is common on the west coast from Point Pedro and Putlam; replacing *Sc. Tristriatus*, from which it is easily distinguishable by its pale colour and the long pencil-tuft at the extremity of the tail, this, however, is often wanting in stuffed specimens, and indeed even in live ones, the hair being but slightly attached to the skin:

## MAMMALIA OF CEYLON.

*Sc. Kelaarti* entirely replaces all the other small *Sciuri* from Tangalle and Hambantotte, and I should fancy extends round to Trincomali. It may be described as very like *Sc. Palmarum* of India, but the head as much redder, the halves of the back and belly are more blended, and the animal is altogether smaller." These three little squirrels, if different are exceedingly affined; and all have the rufous colouring under the tail which is never seen in *Sc. Palmarum*. It would be interesting to ascertain if their voices differ, for that of *Sc. Tristriatus* is remarkably unlike the voice *Sc. Palmarum*.

In XVIII, 603, it is remarked that there are no *Sciuri* more difficult to understand than the group exemplified by *Sc. Modestus*, Muller, &c. The three Darjiling specimens there referred to as having the thighs externally of a bright ferruginous colour, exemplify the *Sc. Lokriah*, Hodgson, apud Gray, who terms it the "Red-thighed Squirrel" (vide *Catal. Brit. Mus. Mammal.*); and the *Sc. Lokriah*, H. apud, Blyth, (J. A. S. XVI, 873) Mr. Gray designates as *Sc. Subflaviventus*, McClelland. In Dr. Cantor's list of the mammalia of the Malayan peninsula *Sc. Modestus*, S. Muller is cited as a doubtful synonyme of *Sc. Tenuis*, Horsfield, and the habitats given by Dr. Muller ("Java, Sumatra, Borneo, Canton,") are transferred, but Mr. G. Moxon has recently presented the Society with a specimen from Malacca, which we take to be the Malayan peninsula race referred to *Sc. Modestus*, and which is very distinct from *Sc. Tenuis* of Java and apparently differs also from the *Sc. Modestus* figured by Dr. Solomon Muller. Length, about 8 inches of tail 9 inches, its hair reaching  $2\frac{1}{2}$  inches farther; hind-foot with claws  $1\frac{2}{3}$  in. Colour of the upper-parts grizzled black and Golden-fulvous, deeply tinged with ferruginous on the croup and tail: under parts pale ashy; and limbs grizzled ashy externally, whiskers long and black, terminal two-thirds of the tail banded with black, the alternating fulvous bars whitish towards the end: no ferruginous on the face, sides and limbs, as in Dr. S. Muller's figure of *Sc. Modestus*. From *Sc. Nigrovittatus*, it differs in having no lateral stripes, nor the rufous tinge about the muzzle and cheeks; also in the decided ferruginous tinge of its croup and tail and the very distinct bands upon the latter. In the same collection were three specimens of *Sc. Laticaudatus*, S. Muller and Cantor, which is doubtless the *Rhinosciurus tupaoides* Gray from Singapore, and possibly distinct from true *Laticaudatus*. One of these has been presented for the Society's museum.

*Muridæ*.—Or the Rat tribe.

(1053) *Gerbillus Indicus*, F. Cuvier; from which we now doubt whether *G. Cuvieri*, Waterhouse, and *G. Hardwickii*, Gray, differ constantly in any respect (vide J. A. S. xv, 138). At least specimens are perfectly similar from different

## MAMMALIA OF CEYLON.

parts of Bengal, S. India, and Ceylon; but we have not yet examined the skull of a Cinghalese example. Dr. Kelaart remarks that Kandyan examples differ in no respect from the Gerbil of the plains of Ceylon.

(1054) *Golunda Elliotti*, Gray, *Mag. N. H.* 1837, p. 586: *Mus hirsutus*, Elliot; *M. coffæus* Kelaart. "The Coffee Rat of Ceylon, a very destructive species, rooting up the coffee trees, and nearly destroying whole plantations in one night, when some plant on which they generally live is scarce in the Jungle," (Kelaart).

(1055) *Golunda Meltada*, Gray, *Ibid*: *Mus lanuginosus*, Elliot; *M. newera*, Kelaart. We have little doubt about the correctness of the identification of this species, although there is no S. Indian specimen in the Society's museum to compare with it. In this type, as in *Gerbillus*, the upper rodentia tusks are distinctly grooved.

(1056) *Mus Bandicota* Bechstein: *M. giganteus*, Hardwicke; *M. ikria*, Buch. Ham; *M. nevorivagus*, Hodgson, &c. "Common in the paddyfields round Cotta, doing great damage to the crops and embankments; the natives consider them very good-eating." (Layard).

(Mr. Layard has also procured *M. Indicus*, Geoffroy, v. *arvicola indica, et bengalensis, et Mus Kok*, Gray, *M. providens*, Elliot, and probably *M. pycioris*, Hodgson, *Ann. Mag. N. H.* XV, 267, if not also *Nesokia Hardwickii*, Gray, *ibid.* X, 265. "Not uncommon about Jaffna. The natives esteem them great delicacies, and they are much sought after.") From a recent letter from Dr. Kelaart, he also appears to have met with this species at Kandy.

(1057) *Mus Decumamus*, L. (*M. Rattus*, L. Included by Mr. Layard. In Calcutta, we have only obtained this species from the shipping, and may remark that there is a brown variety of it so much resembling the *M. Setiger*, Horsfield,—an arboreal species which is very unlikely to be often conveyed about in ships,—that we cannot help strongly suspecting that the black and brownish specimens from Van Dieman's Land assigned to *M. Setiger* (*setifer*) in Mr. J. E. Gray's catalogue of the mammalia in the British museum, pertain really to the European Black Rat. Of this we have also fine examples from France.)

(1058) *M. Nemoralis*, Blyth, n. s. (*M. setifer* apud Layard, (probably not, however, as Mr. Layard supposed *M. setifer* was "procured in a paddy field near Galle.") with a considerably longer tail, exceeding the head and body in length in the proportion of five to four. In *M. Setifer*, the tail is shorter than the head and body. The whiskers are also blacker, at least than in what we take to be a half-grown specimen of *M. Setifer* from Malacca. Dr. Kelaart sent an adult specimen and one two-thirds grown from Ceylon; and Mr. Firth lately obtained three young living examples from a

## MAMMALIA OF CEYLON.

huge nest placed among the branches of a dense mango tree, in the vicinity of Calcutta. Two of these soon after made their escape, and the third we possess in spirit. We have since ascertained its occurrence in the Botanic garden, and other likely sites in the neighbourhood of Calcutta. We had not the opportunity of actually comparing an adult with the Ceylon specimens, but it certainly appeared to be specifically identical with them; the belly being merely somewhat albescent. It exhibited a manifest affinity for *M. Rufescens*, but was much larger, less rufescent, and the belly dull whitish instead of pure white. Shot on the bough of a tree.

(1059) *M. Rufescens*, Gray: *M. flavescens* et *M. rufus*, Elliot (nec Waterhouse); *M. arboreus* B. Hamilton, Ms. This also is a tree Rat, keeping especially to cocoa-nut palms, though by no means confined to them. According to Buchanan Hamilton, it nestles in the cavities of trees, and not (like the preceding species) among the branches. We have obtained a single individual variety, in which the white belly is much less abruptly defined than usual. One that escaped in our private residence took up his abode for some days (till we saw no more of him) on the top of a glass-folding door, not burrowing like the common house Rat. They do, however, as Buchanan Hamilton remarks, visit out-houses and similar places by night; but pass the day on trees, chiefly cocoanuts (being very destructive to the young fruit,) and bamboos.

(1060) *M. Kandianus*, Kelaart, n. s. very like the preceding species, but the fur softer and of finer texture, and less rufescent in color. Whiskers very long, fine, and black. Peculiar to the mountains, and we strongly suspect it to be only a mountain variety of *M. Rufescens*; but require to examine more perfect specimens and to compare the crania and dentition, before coming to a final decision *M. Niviventer*, Hodgson, would seem to be affined.

Other species of *Mus* are enumerated by Dr. Kelaart, as inhabitants of Ceylon; but they require further examination.

(1061) *Mus Oleraceus*, Sykes, is also a Bengal animal; and the Society possesses a specimen from Assam quite similar to others from S. India. *M. Dumeticola* and *M. Povens* Hodgson, require to be carefully compared with it.

(1062) *Mus Terricolor*, Blyth, must be closely affined to *M. Cervicolor*, and *M. Strophiat* Hodgson, Mr. Elliot sent it from S. India together with *M. Lepidus*, from which he did not distinguish it. Indeed it much resembles that species in form and colour, but the face is very much shorter, and the fur short, soft, and not spinous in the least degree. Its colour varies, however, according to the soil; those of the alluvium of the Ganges being darker than specimens from the ferruginous soil to the westward. All have the

## MAMMALIA OF CEYLON.

hue of the upper-parts as in the various affined species. Length  $2\frac{1}{2}$  in; of tail  $2\frac{1}{8}$  in; ears  $\frac{1}{4}$  in; hind-foot  $\frac{9}{16}$  in. Inhabits gardens, and is very numerous in the open fields; together with *Gerbillus Indicus* and *Mus Indicus*.

(1063) *Mus Mani*, Gray, who refers to this the *M. musculus* apud Elliot, is consequently the common house Mouse of India generally, which differs from *M. Musculus* in having a longer tail, and shorter fur which is not so dark in colour. Length of head and body 3 in. and of tail  $3\frac{1}{2}$  in. *M. Dubius*, *M. Homourus*, and *M. Urbanus*, Hodgson, required to be compared with it.

(1064) *Mus Berdmorei*, a remarkable species from Mergui by the name *M. Berdmorei*. Length about a foot, of which the tail is not quite half; ears posteriorly  $\frac{3}{8}$  in. hind foot,  $1\frac{3}{8}$  in. Fur shortish, even, coarse and hispid but not spinous, of one quality, with no long hairs intermixed: its colour grizzled grey above, unmixed with rufous; below and on the feet pure white. Rodential tusks white. Tail rather more copiously clad than usual with short hairs.

(1065) *Hystriidae*. A young Cinghalese Porcupine sent alive by Mr. Layard, and since mounted in Society's museum, is evidently of a new species most nearly affined to the common but undescribed porcupine of Bengal. The last and most satisfactory authority upon the species of porcupine is Mr. Waterhouse's 'Natural History of the Mammalia,' Vol. 2. This author reduces the known species of *Hystrix* as now limited (including *Acanthion*, F. Cuv.) to four, viz., two crested species of large size, the European and N. African *H. Cristata*, L. and the Asiatic *H. Hirsutirostris*, Brandt (v. *leucura*, Sykes); and two crestless species of much smaller size, the Sub Himalayan *H. Hodgsonii*; Gray (v. *alophus*, Hodgson), and *H. Longicauda*, Marsden (v. *Acanthion javanicum*, F. Cuv.), of the Malayan peninsula and archipelago. Of these the Society's museum contains two skulls, a stuffed head, ditto very young animal, and a flat skin (deprived of the crest) of a half-grown example, of *H. Hirsutirostris*; flat skins of old and young of *H. Hodgsonii*; and a stuffed specimen of *H. Longicauda*: also three skulls (one of them from Assam), agreeing with Mr. Waterhouse's description and figures of the skull of *H. Hodgsonii*; but on two of them the names "*Hystrix cristata*" and "crested porcupine" are written by one of our predecessors, so that they perhaps belong to the small crested species of Bengal, and not to the Sub-Himalayan crestless Porcupine. In Mr. Walker's list of the mammalia of Assam (*Calc. Journ. Nat. Hist.* III, 267) the only porcupine mentioned is *H. Cristata*, which should at least indicate the existence of one of the crested species in that province. No. 1 is that of an old animal, and is rather larger than the two described by Mr. Waterhouse; measuring  $5\frac{1}{4}$  in. in total

No. 3 is that of a young animal, in which the naso-frontal sutures form each a straight line, meeting its opposite at an obtuse angle posteriorly; this, however, is merely due to immaturity, the forehead not having commenced to budge as in the adult animal. *H. Hodgsonii* and *H. Longicauda* are nearly affined species, but exhibit well marked distinctions in the cranium: and externally they are most readily characterized apart by the latter having a strongly marked white demi-collar, proceeding upward from the throat, which either does not occur or is barely indicated in the other and by its body spines (i. e. spinous bristles, as distinct from the quills,) terminating in sharp and rigid points, not flexible and setaceous tips as in *H. Hodgsonii*.

(1066) *H. Bengalensis* Blyth. The common Bengal Porcupine (and of Assam?, Sylhet, and Arakan, rare near Calcutta.) *H. Bengalensis*, resembles the two last mentioned in size and general character; or it may attain to a larger size, though not nearly to the magnitude of *H. Cristata* and *H. Hirsutirostris*. Since the above descriptions were written, we have seen, in the Barrackpore menagerie, fine living examples of *H. Hirsutirostris*, *H. Bengalensis*, and the *Atherura* inhabiting the Tippera and Khasya hills, which latter is well figured and described by Buchanan Hamilton, and like them it does not possess the two great lateral masses of very long, slender and flexible quills, impending and concealing the much shorter, thick, rigid and acutely pointed quills which constitute the armature of the animal: but it has only a very few long and slender quills, gradually thickening in the basal half and attenuating much in the terminal half, intermixed with the ordinary or weapon-quills towards the front and at the sides. The latter are much longer and thicker than in the two crestless species; and the body spines are still flatter and more strongly grooved, and terminate towards the neck in slight setae, towards the quills in rigid points. There is a distinct but small thin crest, (not dense and massive, as in the two large species,) the longest bristles of which measure 5 or 6 in., and are tipped with white for the terminal third: and the white demi-collar is as strongly marked as in *H. Longicauda*. General colours as in *H. Hodgsonii*; the quills generally having the basal half white, the rest black, most of them with a white tip more or less developed: the few long and flexible quills are white with a narrow black band about the centre. Tail as in the two crestless species, with similar pedunculated quills.

The Cinghalese Porcupine sent by Mr. Layard, though young, we do not hesitate to name as another distinct species.

(1067) *H. Zeylanensis*, Blyth. Fortunately we have a stuffed Bengal Porcupine of about

the same size and apparent age to compare with it. It is nearly affined to *H. Bengalensis*, with a similar but more developed crest of long bristles; these are of the same brown colour as the body spines, and have each one obscure pale annulation and beyond it a white annulation at less than two-thirds of its length: the quills are slenderer than in the porcupine of Bengal, and are black, with white extreme base; mingled with others longer and more slender, which are chiefly very pure white, often with dark base. Spines, much flattened and very much grooved, and coarser over the limbs than in *H. Bengalensis*; the anterior terminating in very slight flexible setae, becoming gradually obsolete towards the quills, upon the hind-limbs especially, the spines are quite as coarse as on the sides of the body; whereas in the Bengal Porcupine they are there much finer and more bristle-like. White demi-collar barely indicated. The general colour is much as in the others, but a little more rufescent, and the spines are even more shining than usual; the white of the quills being also much purer than in either of its congeners. The body-colour pales remarkably on the hind-limbs. The ear-couch is formed most as in *H. Hirsutirostris*, being somewhat squared above, with strongly marked posterior angle; and (in the specimen at least) they are much more scantily clad with hair than in *H. Bengalensis* and *H. Hodgsonii*. Lastly, the pedunculated quills of the tail are considerably more elongated than in either of the other species. In the small well mounted specimen described, standing  $5\frac{1}{2}$  in. high at the shoulder, some of the bristles forming the crest are 6 in. long: in a Bengal Porcupine of the same size they are not  $4\frac{1}{2}$  in; but still appear conspicuously in the latter, from being all broadly and evenly tipped with white. It is not improbable that the large *H. Hirsutirostris* may likewise be proved to inhabit the same island; and likely enough there is a second and small species, perhaps *H. Zeylanensis*, in India. The latter is described by Mr. Layard to be common in the Chilaw and Jaffna districts, doing great damage to the cocoanut trees when young and tender. The Natives term them *Oat Oara* ('thorn pig').

The skulls of *H. Bengalensis* and *H. Zeylanensis* remain to be examined and compared with those of *H. Hodgsonii* and *H. Longicauda*; for to the latter, and not to the two great Porcupines, these two small crested species are more immediately affined. The want of crest is accordingly no distinction of *Acanthion* from *Hystrix*, as Mr. Gray would separate them, but the absence of the two great lateral masses of very long slender quills, impending the others and even the tail in the two large species, affords a better external distinction. We follow Mr. Waterhouse and others, however, in assigning the whole to *Hystrix* as now limited.

(1068) *Leporidae*. The Hare of Ceylon is *Lepus Nigricollis*, F. Cuv. (*L. melanaachen*, Tem) identical with the species of peninsular India, Java, and the Mauritius, from each of which regions the Society possesses a specimen. The Hare of Bengal and all upper India is *L. Ruficaudatus*, G. Geoffroy; Mr. Waterhouse erroneously supposing *L. Nigricollis*, F. Cuv., to be the Hare of Bengal. We know but of twelve species of *Rodentia* in all Lower Bengal, which are as follows:—1 *Sciurus Palmarum*,—2 *Gerbillus Indicus*,—3 *Mus Indicus*, Geoffroy (M. Kok, Gray),<sub>1</sub> common field Rat.—4 *M. Terricolor*, Blyth, common field and garden Mouse.—5. *M. Bandicota*, in marshy localities.—6 *M. Decumannus*.—7 *M. Rattus* observed only among the shipping in the river.—8 *M. Flavescens*, chiefly in coconut trees and about bamboos.—9 *M. Nemoralis*, trees,—10 *M. Manei*, Gray; domestic Mouse.—11 *Hystrix Bengalensis*.—12 *Lepus Ruficaudatus*.

(1069) *Pachydermata*. The [Pachyderms of Ceylon are the Elephant, the wild Hog, and the Dugong; which last according to Mr. Layard is common in the Bay of Calpentya, on the western coast, and bears the name of *Talla Maha* among the natives who highly esteem its flesh. A skull of a Cinghalese wild Boar, sent by Mr. Layard differs much in contour from skulls of the wild Boar of India; indeed so much, that we feel justified in denominating it as a peculiar species.

(1070) *Sus Zeylonenses*, Blyth, n. s. skull longer than that of the Indian Boar, nearly straight in profile, very much contracted at the vertex. Palate contracting posteriorly to less than 1 in. from the magnitude of the last molar, which is considerably larger in both jaws than in the wild Boar of India, the upper measuring  $1\frac{3}{4}$  in. long, by  $\frac{1}{8}$  in. broad anteriorly. Vertex narrowing to 1 in. only in breadth. Total length of skull, from vertex to tips of nasals,  $16\frac{1}{4}$  inch. Altogether, this skull approximates closely in contour to the figures of the skull of *Sus Barbatus* by Dr. S. Muller and M. Temminck.

Note.—There are two races, if not even species, of Indian wild Boars distinguished respectively by a broad and by a narrow vertex in specimens of the same age. In the former the vertex where narrowest measures  $2\frac{1}{4}$  in. wide; in the other barely  $1\frac{3}{8}$  inch. In other respects they are similar, except that the molars are larger in the race with narrow vertex. This so far as we have seen, is the Bengal animal; whereas that with broad vertex inhabits Kutak, and perhaps the Indian peninsula generally. A skull from Arakan exhibits an intermediate character, with vertex  $\frac{3}{4}$  inch wide, and the molars large. The Bengal Boar has long borne a reputation for higher courage than that of the upper Provinces at least, which may depend upon its special distinctness. While so many affined species of *Sus* have been distinguished by the Dutch Zoologists in the

archipelago, it is not unlikely that a plurality of continental species may have remained undetected.

In Dr. Solomon Muller's figures of the skull of *Sus Ferrucosus* the young but full grown animal is represented to have a broad vertical plane which is excessively contracted in an old animal: but the oldest Indian skull of several now before us is one with the broad vertical plane. Since writing the above we find that Mr. Gray distinguishes a Boar skull from the Nilgiris by the name *Sus Affinis*; while specimens from the Nepal "hills" and *Tarai* and one from Malabar, he designates *Sus Indicus*.—*List of the Osteological specimens in the collection of the British Museum.*

## RUMINANTIA.

(1071) *Cervidae*. The "Elk" of Ceylon appears to *Rusa Hippelaphus* of India generally, vel *cervus equinus*, F. Cuv., of the Malayan peninsula, Sumatra, and Borneo; found also in the intervening Burmese countries. *Axis Maculatus* is common: also *Muntjacus vaginalis* of which the heads of both sexes were sent for identification by Dr. Kelaart. *Meminna Indica* abounds. "The *Moschidae*," writes Mr. H. N. Turner, jun. (*Ann Mag*, N. H., 2d series, VI. 482) "must, of course be distinguished from the *cervidae* by their trilocular stomach, and by the presence of the gall bladder." We have never found the latter to exist, however, in the chevrotains. Lastly Dr. Kelaart informs us of the existence of a species affined to *Axis Porcinus* and probably undescribed; living examples of which he has recently shipped for the London Zoological gardens. These, we now learn, have arrived in London, and are considered to be distinct and new. We are also informed that the (so called) Hog Deer of the banks of the Indus (C. Dodin? Royle,) is distinct from the *Axis Porcinus* of Bengal, Nepal, Assam, Arakan, Tenasserim, &c. While on the subject of Deer, it may be remarked that Mr. Gray, in his list of osteological specimens in the collection of the British Museum, give as distinct species of the Elaphine group "*Cervus Cashmirensis*, Falconer MS.,<sub>1</sub>" and "*Cervus* (Wallichii?) *Affinis*" of Mr. Hodgson. We have little doubt that these will prove to be the same, and refer to figs. 8 and 9 of the plate accompanying J. A. S. X, 750 representing a horn of the Kashmir Stag, for comparison with Mr. Hodgson's various figures of those of *C. Affinis*, J. A. S. X, 722; XIX, 466, 519). We continue to be, as formerly, of opinion that the species is *Cervus Wallichii*, Duvaucel, figured and described from a young animal at that time living in the Calcutta Botanic Garden; the identical pair of horns it bore being now in the Society's museum, and represented J. A. S. X. 750 pl., fig. 7. In all probability, it is also the *Irbisch* or great stag of Siberia mentioned by Stahlenberg; if not likewise the Persian *Maral*, which we saw alive in

London; and (as remarked on a former occasion, J. A. S. X., 747,) we 'cannot doubt that, with full maturity, this noble species possesses a terminal crown to its antlers, assuming thus every feature of a typical member of the elaphine group,' the crown being, however, probably as in the Wapiti (*O. Canadensis*, vide X. 75, pl., figs. 4, 6), rather than as typically in the European Stag (*O. Elaphus*). The *O. Wallichii* as figured by Mons. F. Cuvier, most closely resembles the Wapiti Stag of North America; and the similitude of the horns (at least at a particular age?) is exhibited in figs. 2 and 8 of the Plate referred to. Compare also the young *Wallichii*, fig. 7, with the young, *Mural*, fig. 10. Since the foregoing was in type, we have chanced to refer to the figure of the Wapiti in Dekay's volume on the Mammalia of the state of New York, and the horns represented in that figure are absolutely similar to those of the great Asiatic Stag, as the latter are given by Mr. Hodgson.

(1072) *Bovidae*. The wild Buffalo is common; and it would seem that formerly *Bos Gaurus* inhabited the island, inasmuch as the *Guavera* of Knox can scarcely refer to aught else; but, if so, it has now been exterminated for nearly a century.

(1073) *Edentata*. Mr. Layard writes—"I think our island *Manis* is identical with the Indian *M. Brachyura*, but it requires identification. It is not uncommon. I have also seen another species which I have little doubt will prove to be the long-tailed Pangolin of authors;" or can this be *M. Leptura*, Blyth, J. A. S. XI, 454, XVI, 1293?

(1074) *Cetacea*. The Dolphins and Porpoises of the coast and the large Whales occasionally stranded, are all in need of accurate determination.

(1075) MAMMALIA, procured at or near the station of Cherra Punji in the Khasia hills, north of Sylhet, described by E. BLYTH, Esq., in Beng. As. Soc. Jour. No. VI of 1851.

(1076) *Presbytis Pileatus*, Blyth, (J. A. S., XII, 174, XIII, 467, XVI, 735. Procured at Cherra Punji.

(1077) *Dysopus Plicatus*, (B. Ham.) nearly as dark coloured as the Malayan race termed *D. Tenuis*, (Horsfield), which, we think, differs not, otherwise than in being constantly of a much darker hue than the ordinary *D. Plicatus* of India.

(1078) *Nycticejus ornatus*, Blyth, n. s. A large and robustly formed typical species, of uncommon beauty. In colouring, it is affined to *N. Tickelli*, Blyth, p. 157. ante; but is altogether stronger, with conspicuously larger and stronger feet, and remarkably elongated ears. It also does not possess the peculiar small flat incisor, situate posteriorly to the contact of the ordinary large upper incisor and the canine, seen in *N. Tickelli*. Colour, a bright pale rusty isabel-line-brown above, (the piles black for the basal

fourth, then whitish, with rusty extremities,) less vivid on the lower half of the back, and somewhat paler below, a pure silky white spot on the centre of the forehead, others on each shoulder and axilla above, and a narrow stripe of the same along the middle of the back; face below the forehead deep brown, including the chin; a broad white demi-collar over the throat from ear to ear; and beneath this is a dark brown demi-collar of similar extent, (passing in a narrow streak upward to the chin), and below this again a narrower pure silk white one, commencing from the shoulders—which below it are again deep brown, continued round to separate the ends of the white band below from the white axillary spot above. Membranes marked as in *N. Tickelli*, or black except the interfemoral which is tawny-red, as also a portion of the lateral membranes towards the body, and the entire limbs and digits. Ear-conch elongate oval, erect, with tragus a fourth of its length, narrow, semi-lunate, and curved to the front. Length (of an adult female)  $4\frac{3}{4}$  in. of which the tail measures  $1\frac{7}{8}$  in.; expanse  $14\frac{1}{2}$  in.; fore-arm  $2\frac{1}{4}$  in.; longest finger  $3\frac{7}{8}$ ; tibia  $\frac{7}{8}$  in.; foot with claws  $\frac{1}{2}$  in.; ears externally  $\frac{5}{8}$  in.; tragus  $\frac{1}{4}$  inch. Procured at Cherra Punji.

(1079) *Talpa Leucura*, Blyth, J. A. S. XIX, 215. Of this recently described species, Mr. Frith has brought thirty-three specimens in spirit, all true to the distinctive characters indicated. In none does the head and body exceed  $4\frac{1}{2}$  inches in length. The species, however, inhabits the plain of Sylhet, and not Cherra Punji as formerly stated.

(1080) *Sorex Peyroletii* (?), Duvernoy. The specimen examined, had been affixed to a thorn by some shrike, as has been several times observed of the common British Shrew by *Lanius Collurio*. Colour darker than usual; but otherwise it appears identical with specimens from various parts, as Almorah, S. India, Maulmein, &c. It is the smallest of all known mammalia.

(1081) *Tupaia Ferruginea*, var. *Belangeri*; *Tupaia de Pegu*, Lesson, Zool. de Belanger, t. 4. *Cladobatus Belangeri*, Wagner.

This race, which abounds in Arakan and the Tenasserim provinces, merely differs from the common *T. Ferruginea*, Raffles, of the Malayan peninsula, in being less deeply tinged (and often not at all so) with maroon on the upper-parts; the colouring being much as in *T. Javanica*, but still having a decided rufous cast as compared with this little species, which likewise is common about Malacca and Singapore, though unnoticed in Dr. Cantor's list of the mammalia of the Malayan peninsula. We cannot regard *T. Belangeri* as distinct from *T. Ferruginea*; and we have not previously seen it from so northern a locality as Cherra Punji, though it probably also inhabits Assam. The species of Central and Southern India, *T. Elliotti*, Waterhouse, is a

## MAMMALIA OF CHERRA PUNJI.

much larger animal, equal in size to *T. Tana* (*V. Cladobates Speciosus*, Wagner), of the Archipelago and the only remaining species of this genus hitherto discovered is the strongly marked *T. Murina*, (Diard), from the western coast of Borneo figured by Dr. S. Muller and M. Temminck.

(1082) *Rhizomys Pruinus*, Blyth, n. s. So far as can be judged from external characters, this quite resembles *Rh. Badus*, Hodgson, of the vicinity of Darjiling, and *Rh. Castaneus*, Blyth J. A. S. XII. 1007, of Arakan, except in being very differently coloured: the fur being uniformly dusky-slate above and below, with hoary tips, which latter are of somewhat coarser texture; on the belly there is a slight silvery shade. All three differ from *Rh. Sumatrensis* (*V. cinereus*, McClelland,) of the Teasserim provinces and Malayan peninsula, in being much less robust, having a much shorter tail, and a dense coat of fine soft fur instead of a thin coat of bristly fur; but their structural characters are essentially the same. An example of the present race was long ago forwarded to the Bengal Asiatic Society from Cherra Punji by F. Skipwith, Esq., C.S., but we deferred describing it until seeing additional specimens. Mr. Skipwith's specimen having old and faded fur is much browner and less slaty than those obtained by Mr. Frith in newly renovated pelage; but the hoary tips are conspicuous in all. It is extremely common at Cherra Punji.

(1083) *Atherura Macroura*? (L.; nec *Hystrix fasciculata*, Shaw). *Hystrix spicifera*, Buch. Ham. MS. The different Asiatic species of this genus remain to be fully discriminated. Mr. Waterhouse refers the Siamese race, with a terminal tail-tuft of "long flattened bristles (somewhat resembling thin and narrow strips of whale bone)," to *Hystrix fasciculata*, Shaw (*V. H. macroura*, Gervais), and he states this to inhabit "Siam and the Malayan peninsula." It is doubtless the species figured, evidently from life, by Gen. Hardwicke: but, if inhabiting the Malayan peninsula, it must co-exist there with *Ath. Macroura*, (L.), apud Waterhouse, which has "the apex of the tail provided with a large tuft of flat bristles, which are spirally twisted, and alternately contracted and expanded." This Mr. Waterhouse gives doubtfully from Sumatra; and it is certainly the common brush-tailed Porcupine of the Malayan peninsula. In the Chittagong, Tippera, and Khasya hills; there is a very similar race to the last, but with the spines shorter and less coarse, excepting those of the croup, the ensemble of the colouring greyer, and the enamel of the front-teeth pale yellow instead of deep buff or orange-yellow. On minute comparison of the skulls, the frontals of the Malayan race are seen to be somewhat larger and more convex, while the parietals are proportionally smaller, than in the Northern race: the palatal foramen, also, is narrower and advances more forward in the

## MAMMALIA OF THE HIMALAYAS.

former, and the inferior lateral process of the superior maxillary, forming the lower border of the great antorbital foramen, is, in the Malayan race, given off anteriorly to the position of the first molar, while in the Northern race it abuts directly on the first molar. If distinct, it should bear the name *Spicigera* given to it by Buchanan Hamilton, who has excellently figured and prepared a good M.S. description of it, founded on a living pair received from Chittagong. "They were brought," he was informed, "from the hills; and, so far as the donor (Mr. Macrae) understands, their habits are pretty much the same as those of the Porcupine of the plains. Both burrow in the earth, live upon roots, and are found either in pairs or families." A specimen brought from Cherra Punji by Mr. Frith corresponds exactly with Buchanan Hamilton's coloured figure.

(1084) MAMMALIA OF THE HIMALAYAS, by WM. OGILBY, Esq., M. A., *Fellow of the Royal Astronomical, Geological, Linnean, and Statistical Societies; Secretary of the Zoological Society in Madras Journal of Lit. and Science, July 1840.*

The Zoology, like the Botany of the Hills, differs essentially from that of the sultry plains of India, which skirt their southern base; though occasionally mixed with tropical forms, it is upon the whole of a character closely resembling that of the more temperate and northern latitudes; and the insulated position of these remarkable mountains, exhibiting, as they do, the rare and interesting phenomenon of a temperate and even a boreal climate on the very confines of the tropic, where the summer heat is necessarily greater than even under the equator itself, are of importance to inquiries connected with the geographical distribution of Animal Life. The principle of animality, possesses an innate power of adaptation which renders Animals in some measure independent of climate, particularly as compared with Vegetables, and which increases in proportion as we ascend in the scale of life. The power which all animals possess, in a greater or less degree, of adapting themselves to different varieties of climate, and of withstanding, uninjured, the effects of temperatures foreign to their natural habits, increases in proportion as we ascend from the lower to the higher tribes, and it will be seen that the Mammalia form one of the most favourable groups for the discussion of this important question. Indeed, were it not from their limited powers of locomotion, they would be the very worst of all, because their high position in the scale of life, and the superior intelligence and resource with which it endows them necessarily protect them against changes and casualties, which would prove fatal to more simply organized beings; but, deprived of the powers of flight, ordinary Mammals have not the means of traversing the wide deserts and

## MAMMALIA OF HIMALAYAS.

oceans, which separate the habitable portions of the earth : the nature of their locomotive powers consequently confines them to particular regions ; and, in spite of the more favourable circumstances of their physical organization, their more varied resource and superior intelligence, they afford better materials for studying the problem of geographical distribution, than the kindred class of Birds, whose faculty of rapid flight enable them to set oceans and deserts equally at defiance, in passing to the most distant quarters of the globe, and, as it were, to choose their own temperature and climate in the boundless fields of air. Hence it is that the circumstances of the important problem of geographical distribution are less favourably presented in Ornithology than in Mammalogy ; but, with this exception, the observation above made holds good throughout all other classes of animals, and the simplest tribes will always be found to present the most certain results. Insulated families also occasionally occur, which possess peculiar advantages for the prosecution of this inquiry ; as, for instance, in the case of fresh-water Fishes, than which I am acquainted with no other group of animals so well calculated to illustrate the laws of geographical distribution, or so likely to repay a careful study under this point of view ; and I am only surprised that no competent Ichthyologist has hitherto occupied himself with so promising an inquiry.

The only other principle which can well be regarded as influencing the geographical distribution of Animals, viz. the dispersion of Plants, upon which all animals live, either mediately or immediately, is obviously subordinate to that of climate, with which it has been shown to be most intimately connected. On a limited scale the distribution of particular species may be seriously affected by the influence which civilization and cultivation produce upon the face of particular countries ; wild animals necessarily disappear with the woods and forests which afforded them food and shelter ; the Wolf, the Bear, and the Beaver, have thus disappeared from Britain ; the Capercalzie, exterminated above a century ago, is once more spreading rapidly over the pine forests of Scotland ; but these are partial cases, which do not bear upon the general problem of geographical distribution ; and it is obvious, that upon the great theatre of nature, climate and temperature are the only laws which regulate it, limited, indeed, by the physical structure of the animals, as has been already observed, and by their powers of transporting themselves to distant regions. Hence it is that terrestrial and fresh-water tribes are more favourable for this study than marine or pelagic ; though even among the latter, the comparative simplicity of their structure, and their consequent susceptibility of changes in temperature, render the habits of different genera and species more definite and confined than might otherwise be expected. Of the former, again,

## MAMMALIA OF HIMALAYAS.

land and fresh-water Mollusks being among the most simply organized, are consequently most limited in point of range ; the species of Insects are almost equally confined, unless in the case of certain tribes, which are susceptible of being transported to distant countries in wood and other extraneous substances ; next follow Reptiles and fresh-water Fishes ; and, last of all, Birds and Mammals ; the former, as already observed, having an almost unlimited range of habitat, from the facilities which they derive from their powers of flight, of passing to the most distant quarters of the globe. The common Sparrow, the Snipe, and the Woodcock, for instance, are found in the Himalayas and in Japan, as well as in the North of Europe ; nature has endowed these birds with means of traversing the arid climes and extensive deserts which intervene between these localities, which she has denied to Quadrupeds ; and hence we must not expect to find the Badger and the Fox so widely distributed as the Owl and the wild Goose. But if the same species of Mammals are confined to particular regions, the great question still remains, whether similar regions, wherever situated, or however separated from one another by intervening seas and deserts, produce kindred or analogous species of Mammals ? and it is the general solution of this question in the affirmative, as far at least as the great continents of the globe are concerned, which renders the Mammalogy of the Himalayas so interesting in this point of a view. We have here an insulated territory on the confines of the tropic, with a climate varying from the most intense heats of the Equator to the greatest rigours of the pole ; and we shall find, in discussing its animal inhabitants, that it presents, as it were, an epitome of the Mammalogy of the world ; an intermixture, or rather a succession of species and genera similar to that which we meet in travelling from India to Kamtschatka, or from Brazil to Labrador. With all the resources at my command, I have found my materials much too limited to give any thing beyond a mere outline of the Mammalogy of the Himalayas. The main points to be attended to and noted down by inquirers and those, unfortunately, which the generality of observers most neglect, are the habits and economy of the animals which fall under their notice ; their manners, whether aquatic, arborial or terrestrial ; whether they inhabit burrows, or reside among thick jungle, or on the naked open plain ; whether they live in society or solitary ; the number of young which they produce at a birth ; their period of gestation ; the duration of life ; their instincts, and the stratagems which they employ to capture their prey or to escape from their enemies ; the nature of their food ; whether they hibernate or migrate from place to place, according to the season ; whether they are turned to any account by the natives, or are capable of civilizing.

pliable to the purposes of commerce or domestic economy. These, and other similar inquiries, of the utmost importance to the philosophical Zoologist, are within the ordinary range of daily observation to most gentlemen in India, with respect to many rare and interesting animals. I shall now proceed to enumerate such Mammals as I know to inhabit the great Himalayan Chain; and without following any formal arrangement, shall throw them into such natural groups or families, as appear best suited to illustrate their geographical distribution with respect to climate and temperature, the principal object of the present Memoir.

## QUADRUMANA.

(1085) *Semnopithecus entellus*. Throughout Bengal and the northern provinces of British India there appear to be only two species of *Simice*, the Hoomman (*Semnopithecus entellus*), and the Bhander (*Papio Rhesus*); both of which ascend the hills to a very considerable elevation during the summer heats, and return again to the plains at the commencement of the cold season. This migration is a very interesting fact in the history of these *Simice*; it is the only instance of a similar phenomenon, which has been recorded of this family of Mammals, and may become of great value in its application to geological reasoning on the climate and temperature of Europe during the tertiary epochs, in the deposits of which periods the bones of Apes and Monkeys have lately been found, associated with the remains of Pachydermata, and other inhabitants of more tropical latitudes. The Hoomman, called *Lungoor* by the Hill tribes, is not unfrequently found at an elevation of from 9,000 to 11,000 feet as among the Pine forests in the neighbourhood of Choor, and sometimes even at the verge of the snow-line. Nay, it even appears to have succeeded in crossing the mountains; Turner mentions having seen a large troop of these monkeys in Bootan, where they are held in the same veneration as in Hindustan; and that it has found its way, and is capable of subsisting in a state of nature, of a considerable elevation, and a comparatively low temperature, is sufficiently evinced by these facts, as well as by the testimony of Fraser, Traill and other intelligent travellers. Dr. Royle found it common enough in the neighbourhood of Hurdwar in April, and on Tuen and Mauma at 9,000 feet of elevation in the latter end of May and in June.—*Ogilby, M. L. J. July 1840, p. 147.*

(1086) *Papio rhesus*. The Bhander, Bender, or Bandar, the Common Monkey of Bengal and Upper India (*Papio rhesus*), though said by Mr Hodgson to exist in the central regions of Nepal, only in the vicinity of the temples, and in a semi-domestic state, whence he conjectures it to have been introduced from religious motives, is also reported to abound in Kumaon; and it is highly probable, that the nearly allied species, viz.

(1087) *Papio Assamensis*, lately discovered by Mr. McClelland in Assam, ascends the more eastern hills, as its congener does the central and western ranges. Of this, however, we have no positive knowledge, though the close affinity of the animals gives a strong degree of probability to the fact; but the various species of Monkeys which Mr. Fraser thinks may be found along the upper courses of the Jumna and Ganges, rest on more questionable authority; and it is not unlikely that this intelligent traveller, as indeed he has himself conjectured, was deceived by distance, variety of size, and other circumstances, which give a very different appearance to individuals of the same species.—*Ogilby, M. L. J. July 1840, page 145.*

(1088) *Cercopithecus radiatus*. Mr. Hodgson gives the Bonnet Monkey (*Cercopithecus radiatus*) as a native of Nepal; but this species is confined, as far as at present known, to the peninsula and western coast of India, and seems to have been confounded by Mr. H. with the *Papio Rhesus*, or Bhander of Hindustan.—*Ogilby, M. L. J. July 1840, page 145.*

(1089) *Hylobates Scyritus*? Mr. Hodgson in a letter to the Zoological Society, written some years ago, mentions that his shooters were once alarmed in the Kachar, or Alpine regions of Nepal, by the appearance of a wild man, which walked erect, was covered with long dark hair, and had no tail. The improbability of finding a real Ape in such a situation led him to question the truth of the report; but it is well known that the woods of the lower ranges to the east of Nepal contain at least one species of Gibbon, *Hylobates Scyritus*, called *Hooloo* or *Hooloc* by the Assamese; and it is not improbable that individuals may occasionally wander to the higher and more remote forests of the Central Hills.—*Ogilby, M. L. J. July 1840, page 146.*

## CHEIROPTERA.

When it is recollected that of the sixteen species of Bats, now known to inhabit the British islands, no fewer than ten have been discovered within the last few years, it will not appear surprising that we should be so imperfectly acquainted with this department of Himalayan Mammalogy. Mr. Hodgson, indeed, is the only author who has furnished us with any details on the subject: his "Synopsis of the Vespertilionidæ of Nepal," published in the Journal of the Asiatic Society of Bengal, vol. iv. p. 499, contains an enumeration of seven species of *Cheiroptera*; but, as he himself very candidly observes, his specific identifications must be received with considerable caution, from his want of access to extensive libraries and museums, for the purpose of comparison. Of the two species of *Pteropus*, for instance, which he has there briefly described under the names of *P. leucocephalus* and *P. pyrrivorus*, the former does not appear to differ from the *P. Medius* or *Edwardsii* of the Plains,

and the probability of its identity with that species is increased by the fact, which Mr. Hodgson mentions, of its only visiting the temperate regions of Nepal during the autumn, returning of course to the more sultry plains of India on the approach of the cold season.

(1090) *Pteropus rubicollis* of Mr. McClelland's "list of objects of Natural History collected in Assam," is likewise identical with the *P. Edwardsii*.

(1091) *Pteropus Dussumieri*. The only other species of tailless *Pteropus* known to inhabit the continent of India, *Pteropus Dussumieri*, is very different in its characters from *Pteropus medius*; and as Dr. Royle brought undoubted specimens of this latter species from the lower hills a little farther west, it is but reasonable to suppose that it is equally common in Nepal, and consequently identical with Mr. Hodgson's animal.

(1092) *Pteropus pyrrhorus*, to judge from the short description given by Mr. Hodgson, appears to be less questionably a new species: it belongs to the second section of the genus, having a short tail, partly free and partly enveloped in the membrane, and derives its specific name from the depredations which it commits among the ripe pears in the central regions of Nepal. The migratory habits ascribed to these *Pteropi* are common to the *Pteropus poliocephalus* of New South Wales, and many other species of the same genus; for these large frugivorous *Cheiroptera* are essentially tropical in their habitats, and only visit more temperate climates during the summer and autumn heats, when the ripe fruits tempt them to wander from their native regions. They are consequently but occasional visitors to the higher elevations and latitudes of the globe; and the *Pteropus dasymallus* and *Pteropus pteropus*, which have been hitherto observed only in Japan, comparatively a high latitude for these animals, do not probably form an exception to the general law.

(1093) Of the *Insectivorous Cheiroptera*, a family far more abundantly and extensively dispersed over the surface of the globe, Mr. Hodgson indicates only five species as natives of Nepal. Three of these are described as *Vespertiliones*, by the specific names of *V. Formosa*, *V. Puliginosa*, and *V. labiata*, and two as *Rhinolophi*, by the names of *Rh. armiger* and *Rh. tragatus* respectively; but without a more careful examination and comparison with other species than Mr. Hodgson had it in his power to make, it is impossible to say how far these Bats may be distinct from, or identical with, species already described. One thing at least is certain, that the temperate and more elevated regions of the Himalayas must contain many species of *Insectivorous Cheiroptera*, still unknown or undistinguished, besides those enumerated by Mr. Hodgson; it has been already observed, that this section of the family is very widely and generally distributed in temperate climates; and the rich harvest which has attend-

ed the researches of British naturalists, within the last few years, in their own country, ought to stimulate our Indian brethren to a pursuit which cannot fail to be rewarded by still more extensive discoveries. It would be extremely interesting, for example, to procure a complete series of Himalayan Bats, with the seasons, temperatures, and elevations at which they were captured carefully noted down, so as to compare them with analogous species of higher latitudes, and thus ascertain what law of succession the different forms may follow, or within what limits they may be confined in respect to temperature, in their geographical distribution over the surface of the earth. Speaking of these *Insectivorous Bats*, Mr. Hodgson observes that "they are neither migratory nor subject to hibernation;" two properties which in more northern climates would be considered incompatible with one another, and which even in the central regions of the Himalayas require a very careful revision before they can be admitted as established facts. I am not aware that these animals ever migrate in any climate; hibernation is the resource which nature has provided to preserve them during the season when their natural food disappears; and it is the general opinion, that within the tropics, the Insect-feeding Bats go to sleep at certain seasons, as they do throughout the winter in more northern latitudes: should the fact be otherwise, it would prove a highly interesting addition to our knowledge of their habits; but it is possible that Mr. Hodgson may have been led into error, by the casual appearance of a few individuals during an occasional fine evening, as sometimes occurs in Britain even in the depth of winter. The subject is well worth the attention of Indian Zoologists.

(1094) *Insectivora*. Ascending gradually from the *frugivorous Cheiroptera* of the Plains of India, which visit the hills only during the summer heats, through the insectivorous genera of the same family, which remain throughout the whole year, we next come to the *Insectivora*, properly so called; a family which belongs almost exclusively to the temperate regions of the earth; and of which it is therefore extremely interesting to find the common forms of Europe and Northern Asia occurring in the analogous climates of the Himalayas. No fewer than three distinct species of Hedgehogs, for instance, have been described from the Western Hills of the Himalayas.—*Ogilby, M. L. J. July 1840, p. 148.*

(1095) *Erinaceus spatangus*, a small dark-coloured species, not more than twice the size of a large mouse;

(1096) *Erinaceus Grayii*, of a grizzled black and yellow, from the spines being annulated with these two colours, rather smaller than the common European species; and

## MAMMALIA OF HIMALAYAS.

(1097) *Erinaceus collaris*, by some supposed to be identical with *E. Grayii*, but easily distinguished by a white collar half surrounding the neck. All these species, however, require a careful revision; they are founded on single specimens, those of the two former deposited in the Zoological Society's Collection, that of the last in the British Museum, and of which a figure is published in the Indian Zoology of Messrs. Hardwicke and Gray. It is possible that more extensive and accurate observation may prove the whole three to be identical: at all events, it is certain that one, or either of these, of a different species (*Erinaceus indicus* of Royle's Illustrations, &c. p. 6.), inhabits the neighbourhood of Delhi, where it would be interesting to observe the phenomena attending its hibernation, such as the temperature of its body, the nature of its respiration, &c. during the period of repose.—*Ogilby, M. L. J. July 1840, p. 148.*

(1098) *Sorex indicus*. Mr. Hodgson, in the letter to the Zoological Society, already referred to, denies that there are any Hedgehogs in Nepal, but mentions a small dull slaty-blue variety of the common Indian Shrew or Musk Rat (*Sorex indicus*), as common in the lower and central regions, to which he speaks of it as being confined. Other species no doubt exist in the more temperate parts of the mountains, though their small size and shy habits screen them from observation.—*Ogilby, M. L. J. July, 1840, page 148.*

(1099) *Talpa* the same gentleman mentions the Mole (*Talpa*), as abounding in the Kachar, or northern region of Nepal, and Traill says it is common in Kemaon; but no one appears to have described, or even examined it, and we are ignorant of every thing relating to it, except the name. It will probably prove to be a distinct species from its European congener, if it exist at all; but the question is involved in great doubt, and is well worthy of a careful examination.—*Ogilby, M. L. J. July 1840, page 148.*

### CARNIVORA PLANTIGRADA.

(1100) *Ursus*. Of the family *Carnivora Plantigrada*, the majority of which likewise belong to the temperate regions of the earth, various forms and species occur among the Himalayas. First of the genus *Ursus*, we have the *Bhalo*, or Common Bear of India (*Ursus labiatus*), and, according to Mr. Hodgson, the Malay Bear (*Ursus Malayanus*), inhabiting the Turais, or sultry regions, at the base of the mountains, to which localities he appears to intimate that they are confined. But the habitat here assigned to the Malay Bear is extremely doubtful. It rests solely on the authority of Mr. Hodgson, who, from the want of proper means of comparison, is often mistaken in the identification of species: moreover, we have never received this animal from any part of Continental India, but only from the great islands of the Indian Archipelago; and it is therefore not improbable that it may have

## MAMMALIA OF HIMALAYAS.

been in this instance confounded with the *Ursus Thibetanus*, which, from the general similarity of the two species, may have readily happened. Mr. Hodgson, indeed, expressly mentions this latter species as an inhabitant of the Central and Northern regions of Nepal; and Dr. Royle informs me, that it is confined among the more western hills, to the Doon and warm valleys, where it is called *Reech* by the natives. Lieut. T. Smith, of the 15th regiment N. I., however, an officer well acquainted with the Mammals of the Himalayas, and a keen sportsman, assures me that the Common Sloth Bear (*Ursus labiatus*) does not ascend above the lower spurs of the great Mountain Chain of Northern India; that it is there replaced by the *Reech* which occupies the whole of the more elevated hills, as far up as the snow line, where it is succeeded in its turn by the *Parji* or yellow Bear (*Ursus isabellinus*), a species hitherto very imperfectly described, though mentioned by every tourist as extremely abundant in the higher regions of the Himalayas. Capt. Skinner met with it in the neighbourhood of Bhairo Ghati; Traill found it in Kemaon, though he says it is peculiar to Bhot; and it is probably the Brown Bear mentioned by Mr. Fraser: so that upon the whole it appears, that whilst the Common Sloth Bear (*Ursus labiatus*) is on all hands admitted to be confined to the sultry plains of India, the *Reech* (*Ursus thibetanus*) succeeds it, as the legitimate representative of the European Bear (*Ursus Arctos*), and of its American analogue (*Ursus americanus*), in the middle or temperate regions of the hills, to be itself replaced among the frozen peaks of the higher mountains, by the *Parji*, or Yellow Bear of the Himalayas (*Ursus isabellinus*), a species in all respects analogous, in its colour and habitat, as well as in its decidedly carnivorous appetite, to its congener, the Polar or Sea Bear of the North (*Ursus maritimus*.)

(1101) *Gulo* and *Meles*. Various animals, either belonging or closely allied to the Gluttons and Badgers (*Gulo* and *Meles*), pre-eminently northern forms, likewise inhabit the elevated ranges of the Himalayas. Among the lower terraces we have the

(1102) *Rattelus mellivorous*, Ratel, called *Peejoo* by the Hindoos, which is common over all the plains of Northern India, and differs from the same animal, as found at the Cape of Good Hope, only in being of a lighter colour on the back.

This wide distribution of the *Carnivori* and the common occurrence of the same species in India, and the most remote parts of Africa, will be more particularly mentioned in the following article: Mr. Hodgson, under the erroneous impression that the *Peejoo*, which the Nepalese call *Bharsiah*, was an unknown animal, and evidently misled by some imperfect or faulty account of its dentition, has recently described it as a new genus under the name of *Ursitæus inauri-*

*tus* ; but the species has long been well known in Europe. M. F. Cuvier figured, and accurately described its teeth in the "Dents des Mammiferes," so long ago as the year 1825 ; and the late Mr. Bennet described and figured the animal itself in 1880, from an Indian specimen then living in the menagerie of the Zoological Society.

(1103) The *Balloo-soor* (perhaps more properly *Bhalloo-soor* ?), *Meles collaris*, which M. F. Cuvier likewise elevated to the rank of a generic form, under the name of *Arctonyx*, upon the faith of a distorted native drawing sent to him by M. Duvaucel, is a real *Badger*, and was described and figured by the celebrated Bewick, at least thirty years before M. Duvaucel's visit to India. It inhabits the northern plains of Hindostan, and probably ascends the hills, but of this fact I have no certain information.

(1104) *Gulo*. Of the Gluttons, properly so called, the *Gulo nepalensis* of Mr. Hodgson, which does not differ specifically from the *Gulo orientalis* of Dr. Horsfield, the only distinction being in a lighter shade of ground colour, inhabits the lower terraces of the hills ; whilst the

(1105) *Wah* or *Chitwah* (*Aturus fulgens*) and the

(1106) *Benturong* (*Arctitis Albifrons*), are said to be confined to the Kachar, and regions bordering on the snow-line. As regards the *Wah*, there is no doubt about the truth of the habitat here assigned to it ; but the *Benturong* is a native of the Indian Archipelago, and of the Peninsula of Malacca ; and I strongly suspect, that it has been confounded with some other animal, perhaps with *Paradoxurus bondar* or some closely allied species. The habitat of *Bootan*, assigned to it in the *Regne Animal*, is altogether erroneous.

Messrs. Gray and Isidore Geoffroy have proposed to consider the *Gulo nepalensis* as the type of a new genus, the former under the name of *Helictis moschata*, the latter under that of *Melogale personata*.

(1107) *Carnivora Digitigrada*. It was mentioned incidentally in the preceding article, that many species of *Carnivora* were common to India, and the Continent of Africa ; and it is not a little singular, that this migration appears to have proceeded exclusively from west to east, and never in the opposite direction ; or, in other words, that whilst the *Carnivora* of Africa have found their way freely into the neighbouring Continent, those of India have never passed the Arabian desert. I do not pretend to account for this. Perhaps it may depend upon the physical character of the two Continents, and the influence which this circumstance exerts in modifying the nature and habits of their respective inhabitants. The Lion of the burning Sahara, for instance, like the wild Taurick or Bedoween of the same regions, would find the parched deserts of Syria and Persia no barrier to his progress towards the East ; whilst, on the other hand,

the Tiger of the moist jungles of Bengal could no more pass the arid plains of Arabia than the puny and luxurious Hindoo, accustomed to the same humid soil and atmosphere. But whatever may be its cause, the fact itself is as undoubted as it is interesting. The common distribution of the *Ratel* over both Continents has been already mentioned. This animal is spread over the whole of Africa ; it is common in every part of the Cape colony, and Denham and Clapperton brought it from Bornou ; and though its geographical limits have not been accurately ascertained in Asia, we know that it abounds on the plains of Northern India, which do not differ much in the physical structure from the Karroos of South Africa. So likewise the Lion (*Felis Leo*), the Leopard or Panther, for they are both the same species (*Felis-Pardus* and *Leopardus*), the Cheetah (*Felis jubata*) the Persian and Red-eared Lynxes (*Felis Caracal* and *Felis Chaus*), the striped Hyæna (*Hyæna virgata*), and the Jackal (*Canis-aureus*), all pre-eminently African species, are found in most parts of India, without offering any striking variety either in form or colour ; whilst the Tigers, Wolves, Paradoxures, &c. of the latter country have never passed far to the west of the Indus, and some of these are even without generic representation on the Continent of Africa ; nor is it less singular that, as far at least as at present known, this migration should have been confined to the *Carnivora*. There is not a single authenticated instance of any of the numerous Antelopes in which Africa abounds above all other parts of the world, and which nature has peculiarly adapted to inhabit the most parched and arid deserts, having crossed the Isthmus of Suez, any more than of the various species of Deer so common throughout the whole extent of Asia having migrated in an opposite direction. If the various indications which Mr. Hodgson has given of the occurrence of species known to inhabit the great islands of the Indian Archipelago, and the southern extremity of the Malay Peninsula, such as the *Benturong* (*Arctitis albifrons*), the Malay Bear (*Ursus malayanus*), and the Javanese Ichneumon (*Herpestes javanica*), in the forests of the Turai, which skirt the southern foot of the Himalayas, should turn out to be correct, (and it is certain that *Felis minuta* and *Gulo orientalis* are common to both these localities), it would appear that India Proper, besides its own appropriate Mammals, is a kind of neutral ground upon which the species of the most distant countries to the east and west of it meet and mingle together. One fact, abundantly singular, but which I have never seen accounted for, is the alleged total absence of every species of the genus *Canis*, so numerous and so common throughout all parts of India, in Burma, Siam, and those other countries east of the Brahmapootra, which compose the great Malay

Peninsula. This is a phenomenon well worth the attention of Indian Naturalists.

(1108) *Felis*. As far as regards the occurrence of the *Digitigrade Carnivora* among the Himalayan Mountains, it is certain that the Lion called *Pany* by the Indians, ascends the western hills to a very considerable elevation. Mr. Fraser often heard of it during his journey to the sources of the Ganges and Jumna, and Bernier, [Dr. Royle says here, "I frequently made inquiries on this subject, and could never learn anything positive on the subject; nor had any of the numerous sportsmen to whom I spoke on the subject, ever seen a Lion or its skin, obtained from within the Himalayas. At present, the Lion is I believe only found to the west of the Jumna, especially on the edge of the desert, near Hansi. J. F. R." whilst travelling to Cashmere, in the train of Aurungzebe, had frequent opportunities of witnessing the chase of this animal: the amusement was reserved for the Emperor alone, and the success of a day's sport was recorded by the Imperial Historiographer in the annals of the empire. The same indifference to climate characterises the Lion in Africa; in the time of Herodotus and Aristotle, he was common among the coldest mountains of Macedon; at the present day he is as often found among the snowy peaks of the Atlas, or on the chilly slopes of the Schneeberg, as in the desert of Barca, or on the banks of the Gareip. Travellers should look for him to the east of the Brahmapootra, as though not known to inhabit any part of Eastern India, the Burmese are said to have figures which can be intended for no other animal, and which can only have been drawn from the living model. The Tiger and Leopard are well known to inhabit every part of the Himalayas, even to the line of perpetual congelation: they exist equally in Japan, in the Caucasus, and in the Altai Mountains in Southern Siberia. The Tiger of Bokhara is less than the Bengal variety, and chiefly confined to the Valley of the Oxus; whilst in Japan he is covered with a thick coat of long soft fur, to protect him from the rigours of that northern climate. The *Cheetah* is said by Mr. Hodgson to occur chiefly among the lower valleys of the Himalayas, but Pallas found it as far north as the Caspian Sea and the deserts of the Khirgis Tartars, so that it may possibly ascend the Hills to a greater height than has yet been suspected. Lieut. Smith mentions a small dark coloured variety of the Leopard, called *Luckur-backer*, extremely fierce, and common in every part of the Hills.

Among the smaller species of the genus *Felis*, the Moormi Cat (*Felis moormansis*) first described by Mr. Hodgson, and hitherto observed only by that gentleman, as likewise the *Felis Bengalensis* or *nepalensis*, are stated to inhabit the middle terraces of Nepal. The *Felis Viverrinus*, first described by Mr. Bennett in 1822, and three years

afterwards by Mr. Hodgson, under the nearly identical name of *Felis Viverriceps*, inhabits the lower terraces and valleys of the Turai *Felis Chaus* (called Biraloo in Nepal), of which I have compared numerous African and Indian specimens, extends over every part of the Hills: it is the *Felis erythrotus* of Mr. Hodgson; and there is a specimen of a Himalayan Cat in the Museum of the Zoological Society, so closely resembling the common Wild Cat of Europe, that it differs only in the absence of the dark transverse and longitudinal stripes which mark that species, and which may not improbably be a mere effect of locality.

(1109) *Paradoxurus*. Mr. Hodgson has described three species of *Paradoxurus* as inhabitants of the Southern, Central, and Northern regions of Nepal respectively, two of which at least I have seen from the more Western Hills; *P. Bondar* (*P. hirsutus*, Hodg.) is confined to the Turai; *P. nepalensis*, Hodg., frequents the middle ranges of the mountains, and *P. larvatus*, (*P. lanigerus*; Hodg.) is only found in the higher regions.

(1110) *Herpestes* two species of Mongoose (*Herpestes*) likewise inhabit the lower terraces; *H. griseus*, called Nyool in Nepal, does not extend beyond the Turai, but *H. Edwardsii* (*H. auropunctata*, Hodg.) ascends the central hills; whilst *Vicerra Rasse* and *indica* and *Vicerra Zibetta* are said to frequent the same localities respectively.

(1111) *Mustelæ*, the true *Mustelæ*, a genus proper to more northern latitudes, abound in the Himalayas, where there appear to be many different species, some of which, according to Mr. Hodgson, differ but little from those of Northern Europe and Asia. It is to be remarked, however, that they have never been properly compared; but it is interesting to find this additional instance of the relation between generic forms and climate.

(1112) In the central region, besides *Mustela flavigula*, Mr. Hodgson mentions two closely allied species, one larger and of a fuller habit of body (query, *Paradoxurus larvatus*?); the other, which he has described under the name of *Mustela Kathiah*, is much smaller, and often domesticated by the Nepalese for the purpose of destroying vermin, and sometimes even large animals. This appears to be the *Kukar* of Kemaon, where it likewise frequents the villages, burrows in the walls of houses, and is similarly protected by the inhabitants.

(1113) The *Mustela lanigera* of Mr. Hodgson resembles the common Weasel of Europe, but differs in its spirally twisted hair; and the same gentleman mentioned another species so nearly approaching our common Pole-cat, that he is unable to perceive any specific difference; however it will probably turn out to be distinct.

## MAMMALIA OF HIMALAYAS.

Both these latter species abound in the northern and central regions.

(1114) *Lutra*. No fewer than seven species of Otters are said by Mr. Hodgson to inhabit the Himalayas; but they require to be carefully studied and compared, before we can venture to pronounce definitely upon their specific distinction. It is certain, indeed, that several species do actually exist in these Hills; Mr. Hodgson has himself given brief characters of four which he regards as new, besides the two common species of the plains, (*Lutrae Nair* and *Leptonyx*), and seems to intimate that the seventh may be no more than a variety of the common European Otter. The following is the substance of Mr. Hodgson's observations in the letter already referred to, and I give them at length in the hope that they may induce other observers to co-operate with that gentleman in filling up the sketch of which he has given an outline. "Of *Lutrae* we have seven species, five differing from the two usually found in the plains, as well as from all described species, except the common Otter (*L. vulgaris*), of which the largest Nepal species seems to be only a variety. It is five feet long, including the tail, and is the largest, though not the longest of our species. It is peculiar to the lower region, where also three other species inhabit: two more belong to the central, and one to the Kachar. One species is yellowish brown all over; the others brown, more or less dark, some having the chin and throat much paler than the rest of the body, and approaching nearly to white or yellow. They differ in length from five feet to one and a half feet; some being quite vermiform, and others as bulky as the Badger. Detailed descriptions, skulls, and skins of these animals, are much wanted."

(1115) *Canis*. Of the genus *Canis*, different species are found everywhere. The common Pariah Dog is universally dispersed through the mountains, but the Thibet Mastiff is confined to the Cachar, into which it is imported from its native country. There are many distinct varieties of the noble animal.

That called *Sassa*, a large black kind, with dew claws on the hind feet, is esteemed the finest; another called *Mustang* is of a bright red colour.

The common Wild Dog, called simply *Jungle Coota* in the Plains and *Buansu* in Nepal (*Canis Duckunensis* of Sykes and *C. primævus* of Hodgson) is only found in the lower regions, but is replaced farther up by two other wild species, likewise called *Jungle Coota* by English sportsmen. Lieut. Smith informs me that one of these is larger and the other smaller than the *Jungle Coota* of the Plains, from which they both differ in having shorter tails and a lighter or more ashy colour: both species ascend the Hills even to the snow line; they hunt in packs, and inhabit ravines and rocky dells; but, being excessively shy are not very often seen. The

## MAMMALIA OF HIMALAYAS.

*Jungle Coota* of the Plains, in other respects, does not appear to me to differ from the *Canis Sumatrensis* of General Hardwick.

The *Kokree*, or small Indian fox (*Canis Corsac, Indicus, Bengalensis Kokree*, &c.); and the *Berria*, or wolf of India (*Canis pallipes*, Sykes), never ascend the Hills.

The Jackall (*Canis aureus*), is however occasionally said to be found in the central regions.

But the higher mountains are inhabited by a very beautiful species of Fox, which Dr. Royle first noticed as the Hill Fox, and of which he brought home the first skin ever seen in England, and which was described at the time in the present memoir, and afterwards in the proceedings of the Zoological Society, part iv. p. 103 by the name of *Canis Himalæicus*. Mr. Pearson then Curator of the Museum of the Asiatic Society at Calcutta, likewise described it about the same time as the latter; and as he had a few months priority in point of publication, his name of *Canis montana* must have the preference.

(1116) *H. Virgata*. The *Hyæna* of India, a native of the Plains, sometimes ascends even to Simla.

## RODENTIA.

The remark which was formerly made to account for our limited knowledge of the *Cheiroptera* and *Insectivora* of these mountains, may be applied with equal force to the present family; viz. that the comparatively diminutive size and timid habits of the animals which compose it screen them from general observation. Still we have much more detailed accounts of the Himalayan *Rodentia* than of either of the two former families, though even these are far from being so complete as could be wished.

The striped Squirrel of the plains (*S. palmarum*), is according to Mr. Hodgson, abundant in the lower hills of Nepal; and I have seen a second species (*Sciurus Lokriah*, Hodg.) of the same size, but of a uniform earthy brown colour, tipped with golden yellow, which is said to be an inhabitant of the central regions. Mr. Hodgson mentioned a third (*S. Lokroids*) similar to the latter, and perhaps not specifically distinct.

(1117) *Pteromys magnificus* and *P. alboniger*, Hodg. Two beautiful species of flying Squirrel are found both in the northern and central regions, but do not extend to the very elevated parts of the mountains. Here, however, are found a small brown kind of Marmot, called *Bhia* by the natives, hitherto undescribed; and an equally undescribed species of Rat, with a tail not more than half an inch in length, most probably a Lemming (*Georychus*, Illiger), if it be not rather a *Lagomys*, of which rare and essentially arctic genus Doctor Royle has brought a beautiful specimen from the Choor Mountain. Captain Herbert, in his tour up the Valley of the Sutlej met with this tailless rat at an elevation of 12,000 feet, and observes that the ground was every

## MAMMALIA OF HIMALAYAS.

where cut up into groves by it in search of food. He conjectures the animal to be a species of *Spalax*, but Dr. Royle is rather disposed to think that it was no other than the *Lagomys*, as he observed the ground similarly cut up in the vicinity of the spot where he obtained his specimen. The circumstance of the tail, however, which, short as it is, is expressly mentioned by both Capt. Herbert and Mr. Traill, appears to me to preclude Dr. Royle's supposition, since the *Lagomys* of the Himalayas, like the rest of its congeners, is absolutely without any rudiment of this organ. It is not improbable, indeed, that species of all the three genera here mentioned may be found among the more elevated ridges of the Himalayas, of which the climate is perfectly adapted to their habits: and it is to be hoped that future observers will direct their attention to the elucidation of this, as well as the numerous other unsettled points of Himalayan Mammalogy, to which I have already been so frequently obliged to refer.

Dr. Falconer, in the report of his recent journey to Cashmere and Little Thibet, mentions a Rodent under the name of the Thibet Marmot, which he says was first found in a bleak and rocky tract of country, immediately after passing to the northern slope of the great Himalayan range; but we have no farther knowledge of its characters: however, this is precisely the locality in which Mammals of this description might naturally be expected to abound.

(1118) *Mus Rattus* and *M. decumanus*. Rats and Mice, differing little, if at all, from our common European species, are abundant in all the houses. Mr. Hodgson, indeed, expressly states that both our black and brown, or Norway rats, are the common species of Nepal, and Mr. Traill mentions them incidentally as inhabitants of the province of Kemaon. This is another interesting and important point of similarity between the Zoology of the Himalayas and that of the more northern parts of Europe and Asia; nor can we attribute the presence of these animals, in this part of the globe, to the introduction of European conquerors, as is well ascertained to have been the case in America and Australia, since they are confined to the mountains, and altogether unknown in the Plains of India, except perhaps in some of the largest seaports. They must consequently have travelled south to reach their present habitat; and, no doubt, exist in Thibet, Tartary, and other intermediate countries, where the climate is suitable, as far as Northern Asia, from which at least one of the species (*M. decumanus*) is said to have been originally introduced into Europe.

Besides these, Mr. Hodgson describes two other species (*Mus niviventur* and *M. nemorivagus*) as peculiar to the Himalayas;

And I have received a Rat from Dr. Royle, which in the dried state of the specimen I cannot

## MAMMALIA OF HIMALAYAS.

distinguish from the common European Campagnol (*Arvicola vulgaris*), a fact the more interesting from this genus being confined to the temperate and colder regions of the Old World.

(1119) The *Bandicoot*, or great Rat of the Plains (*M. giganteus*) does not exist in Nepal; but various kinds of Field Mice, of what precise species is not mentioned, are stated to be sufficiently common.

(1120) The Porcupine (*Hystrix cristata* var. *leucurus*, Sykes) is found in Kemaon, and the lower and central regions of Nepal.

Mr. Hodgson mentions two species of Hares as inhabiting Nepal. One he calls the common small species (probably the black-necked Hare of F. Cuvier, '*Lepus nigricollis*'), which, he says, is confined to the Turai; the other, which he considers a new species, as large as the common English Hare and nearly resembling it, inhabits the higher and colder parts of the mountains. This is *probably* the red-tailed Hare of M. Isidore Geoffroy St. Hilaire, (*L. ruficaudatus*), of which Dr. Royle obtained a specimen at Hurdwar (?) and which, he informs me, is very common in the Doon and in the neighbourhood of Delhi. As M. Is. Geoffroy's short description of this species is necessarily imperfect, from the mutilated state of the only skin which he had an opportunity of examining, the following more detailed account will not be unacceptable to the scientific Zoologist:—

The skin obtained by Dr. Royle is that of a full-grown female; it is in perfect condition, and measures one foot ten inches from the nose to the origin of the tail: the ears are about five inches in length, and the tail four inches. The face, back and sides are regularly brindled or variegated with alternate wavy lines of black and light sandy brown, arising from the hairs on those parts being annulated with these two colours. The whole coat is short, smooth and glossy; it consists of a short fine internal fur, of a cotton texture, and pale bluish white colour, and of a long, coarse, external hair, which, as just observed, is annulated with black and light sandy brown, and gives the general colour to the upper parts of the body. In the distribution of these colours, each hair is divided into three equal parts, the top and bottom being black, and the centre light reddish brown. The dark colour predominates most on the face, hips, and along the median line of the back, but becomes gradually fainter upon the shoulders and flanks, and is separated from the pure white of the belly by a narrow band of pale rufous. The cheeks are grey, pointed or intermixed with black; a light grey spot occupies the space in front of each eye; the chin is also grey, and the moustaches long and stiff, black at the roots and grey at the points. The ears appear to be reddish brown tipped with black, but the hair has been partly rubbed off in the specimen described, which pre-

## • MAMMALIA OF HIMALAYAS.

vents me from speaking with certainty. The whole upper part of the neck is pure unmixed sandy red, the fur being of the same quality as the internal fur upon other parts of the body, and without any intermixture of the long external silky hairs. The outer face of the arms, the whole of the fore legs, and the outer face of the hind, are also red; the tail red, or rather reddish brown above, and pure white beneath; and the belly and under parts of the body unmixed white. The animal had probably been killed whilst suckling her young, as the skin exhibited four very large teats, one pair on the breast and the other on the abdomen. These were all I could observe, but there may have been more, as the skin had been a good deal rubbed about these parts.

(1121) *Lagomys Roylei*. But by far the most interesting and unexpected acquisition, which Dr. Royle's discoveries among the Himalayas has produced to the Zoologist, is a new and beautiful species of *Lagomys*, a genus heretofore only found in Northern Asia and among the rocky mountains in North America. This discovery, of the greatest importance to our inquiries into the principles which regulate the geographical distribution of animals, is entirely due to Dr. Royle, and furnishes another, and a most marked instance of the paramount influence of climate upon the dispersion of animals, as well as vegetables. Unfortunately, the only skin which Dr. Royle has brought to England, is too imperfect to admit of so detailed a description as would be desirable. The skull has been taken out, (it is now in the Museum of University College, and, Professor Grant informs me, exhibits the same form of dentition as the other species of *Lagomys* described by Drs. Pallas and Richardson), and the hind legs cut off, but in other respects it is in a sufficiently good state of preservation to enable me to assign its specific characters. I propose, under the specific denomination of *Lagomys Roylei*, to dedicate it to my friend Dr. Royle, in commemoration of the important service which that distinguished Botanist has rendered by its discovery to the kindred science of Zoology.

*L. Roylei* more nearly resembles the *Sulgan* (*L. pusillus*, Pallas), and the American species (*L. princeps*, Richardson), than either the *Pica* or *Ogotona* (*L. alpinus* and *Ogotona* of Pallas). With the exception of the *Pica*, however, it is considerably larger than any other species of *Lagomys*: the skin here described, notwithstanding its imperfect state - for the hinder parts have been partially mutilated, measuring eight and a half inches in length, which is more than one third as large again as the *Ogotona*, *Sulgan* or the American species. From the *Ogotona*, however, it is easily distinguished by its colours, which, in that species, are light grey above and pure white beneath as well as by its naked color.

## MAMMALIA OF HIMALAYAS.

The triangular form of the ears in *L. pusillus*, prevents that animal from being confounded with any other species, and the *Pica* (*L. alpinus*), which alone approaches the size of *L. Roylei*, is at once distinguished by the sandy red colour of its fur. The *L. princeps* of Dr. Richardson is the only remaining species of the genus at present known; it is very similar to our animal in the colour and quality of the fur, but may be readily distinguished by its inferior size, and by the deep black hair which covers the external surface of its ears, and which is replaced in *L. Roylei* by long fur of a pure white colour.

The fur of this species is of two kinds, a very soft and fine internal one of a beautiful blue black over every part of the head and body, as well above as below, and a coarser external kind, of the same colour at the base, but afterwards marked with a broad ring of a greyish yellow colour, and finally tipped with dark brown. These two kinds of fur, however, are not produced by an actual difference in the individual hairs; on the contrary, the same hairs exhibit both the appearances here described, being extremely soft and fine at the root, and assuming a harsh and rigid structure towards the extremity. These harsh tips, being the only parts of the fur seen from without, give their general colour to the whole body. On the upper parts of the body, the head, back and sides, this is uniform brown, slightly mixed with yellowish grey, very dark on the back, much more so, for instance, than in the common Rat (*M. Decumanus*), but rather paler on the sides, and yellowish white on the belly; the hairs on this part wanting the harsh brown point, though in other respects perfectly similar to those of the back. The fur on the body is about an inch in length, and nearly as long on the head, which gives the face a rough shaggy appearance. The nose is entirely covered with short harsh hair of a uniform brown colour; the upper lip is bilobed as in the Hare; the ears are of an elliptical form with regularly rounded tops, covered internally with very short brown hair, and on the outside with long white hair at the base, and short brown at the top, the posterior edges having a scarcely perceptible narrow white border. They are about half an inch broad and three quarters of an inch in length, with a small internal lobe about a quarter of an inch long, and have the folding inwards of the anterior margin, and, consequently, the resulting funnel shape of their basal portions, which Pallas noticed in the species of Northern Asia. Dr. Richardson could observe nothing of this appearance in his *L. princeps*, but I presume this must have arisen from the imperfect state of his specimens in a part so liable to be injured, since an individual in the British Museum exhibits the structure too obviously to have otherwise escaped the notice of that accurate Zoologist. (The author of the

*Roylii* are nearly as long as the head and ears together, and of a uniform brown colour. The arms and fore-arms, and, I presume, the thighs and legs, for, as I have already observed, the posterior members are wanting in the specimen, are covered with fur of the same colour and quality as that on the body, only shorter; but the whole upper face of the carpus, and probably also of the tarsus, is covered with short adpressed hair of a bright reddish yellow colour. The soles of the fore feet present four naked tubercles, corresponding to the extremities of the toes, and a fifth, considerably farther back, which represents the heel, and is separated from the others by a space covered with very short brown hair. The thumb is situated behind the other toes, and, like them, has a small sharp claw of a dusky horn colour.

Dr. Royle obtained his specimen on the Choor Mountain. I take it to be this animal which Captain Mundy met with during his interesting tour recently published, and which he describes as something between a hare and a guinea-pig; and it is probably, also, the tailless rat which Turner observed in Thibet, where the banks of a lake were everywhere perforated by its burrows. I have since seen perfect specimens of this animal, but have nothing to add to the description here given.

## EDENTATA.

Of this family, the only species known to inhabit the Continent of Asia, the short-tailed Manis, or Scaly Ant-eater of authors (*Manis pentadactyla* of Linneus, *M. macroura* of Desmarest) is found in the lower and less elevated parts of the central regions: but all the *Edentata* are essentially inhabitants of the warmer parts of the earth, more especially of tropical America, and we cannot therefore expect to find their forms reproduced in the Himalayas. Mr. Hodgson has described the Manis of Nepal as a new species, under the name of *M. auritus*, on the supposition of its being distinct from the common species of the plains of Upper India, the *Badjarkita* of the Bengalese (*M. macroura*), which has been known ever since the expedition of Alexander the Great, and is mentioned by Ælian under the name of *φάρταγν*; but Mr. Hodgson in this as in many other instances, has been misled by Griffith's translation of the *Regne Animal*.

## PACHYDERMATA.

- (1122) *Rhinoceros unicornis*.—The great Saul Forest, which extends for many hundred miles along the bases of the Himalayan Mountains, affords shelter to vast multitudes of animals, of which it is probable that many species still remain undescribed. Among other genera, the large *Pachydermata* abound in these situations; the Elephant and Rhinoceros (*Elephas indicus* and *Rhinoceros unicornis*), are extremely numer-

city, make frequent inroads into the lower hills, and commit great depredations among the crops of the natives. The Indian Rhinoceros affords a remarkable instance of the obstructions which the progress of knowledge may suffer, and the gross absurdities which not unfrequently result from the wrong application of a name. This animal, to whose horn the superstition of the Persians and Arabs has in all ages attributed peculiar virtues, became known to the Greeks through the description of Ctesias, a credulous physician of that nation, who appears to have resided at the court of Persia in the time of the younger Cyrus, about 400 years before the birth of Christ. His account, though mixed up with a great deal of credulous absurdity, contains a very tolerable and perfectly recognizable description of the Rhinoceros, under the ridiculous name, however, of the *Indian Ass*; and as he attributed to it a whole hoof, like the horse, and a single horn in the forehead, speculation required but one step further to produce the fabulous Unicorn, such as it appears in the royal arms of England, and such as it has retained its hold on popular credulity for the last two thousand years. The works of Ctesias have perished, but this curious passage is preserved by Phocius; Aristotle adopted his statements regarding the *Indian Ass*, from Ctesias; and no other passage of his writings has given rise to a tenth part of the commentaries, discussions, and speculations which have originated in this. Religion was, as usual, pressed into the discussion, and as the Septuagint had used the word *Monoceros*, it was at one time next to rank heresy to doubt the existence of the Unicorn, and might have brought the imprudent sceptic to the stake. But it is not my intention to renew this fruitless and childish discussion; my only wish is to point out the perfect applicability of Ctesias's description to the Indian Rhinoceros, as it is now well known to naturalist; those who wish to pursue a subject of considerable interest in the history of human knowledge, will find many curious details in the writings of the learned Bochart, in Scaliger, Hardouin, Sivery, and others of the older commentators on Aristotle and Pliny.

(1123) *Sus*. Wild Hogs, but of a smaller variety than those of Bengal, are extremely numerous in all the wooded parts of the mountains; they do not appear to be specifically different from the common wild boar of Europe.

(1124) *Equus*. Horses do not breed on the southern face of the mountains, but are imported from Thibet. A valuable and sure-footed variety, called Tangun, is described by Turner.

The Ass does not appear to have been introduced into any part of the mountains, at least neither Dr. Hamilton nor Mr. Hodgson makes any allusion to its being found in Nepal, and Mr.

## MAMMALIA OF HIMALAYAS.

Traill expressly states that it does not exist in Kemaon.

The Dziggetai, however (*Equus hemionus*), is found on the plains of Tibet and Tartary, and is called *Kiang* by the natives.

### RUMINANTIA.

(1125) *Ruminantia* of the Himalayas, as composed of the larger four-footed game most commonly followed by sportsmen, are probably better known than any other department of Hill Mammalogy. Yet even here much still remains to be done to make us thoroughly acquainted with all the different species or varieties which have been mentioned by Mr. Hodgson and other writers; the nomenclature, in particular, is extremely confused, and there is strong reason to believe that the number of species, particularly among the deer tribe, has been greatly increased by the variety of names given to the same animal in the ever varying dialects of the hill tribes. I have, however, only mentioned those of which the existence is known with some degree of certainty.

(1126) *The Musk*. (*Moschus moschiferus*), called Kastooree, is not uncommon in the higher hills. It is said to derive its peculiar odoriferous secretion from feeding on the Kastooree plant, a kind of ground nut, which is strongly impregnated with the same pungent scent, and which the animal digs up with its long tusk. Mr. Hodgson, in a recent number of the Journal of the Asiatic Society, expresses his belief in the existence of three different species of this animal among the Himalayas, and even assigns them distinct names; but the characters are founded entirely on the difference of colour, which is too variable to be depended on for the purpose of specific distinction; and, in fact, Lieut. Smith assures me that the colours vary with the age of the animal; a remark on which I am disposed to place the greater reliance from its agreeing with my own observations, made on many individuals preserved in the museums of this country and the Continent. Whether the "Second species of Musk," mentioned by Dr. Falconer as having been discovered during his recent journey into Cashmere and Little Tibet, be founded on more important characters, we have no means of ascertaining, that Naturalist not having yet published his observations.

(1127) *Jhon Laghuna and Khar Laguna*. Of the genus *Cervus*, the Chittra or Spotted Axis (*C. axis*), and the Laguna or Para and Sûgoriah, called also *Jhon Laghuna and Khar Laguna* spotted and brown varieties of the Hog-deer (*C. porcinus*) are common in the lower hills and forests, but do not ascend the mountains. The specific distinction or identity of the two latter animals has long been a subject of dispute among naturalists; Lieut. Smith believes that the spotted variety is only the young; but I have myself seen animals at least three or

## MAMMALIA OF HIMALAYAS.

four years old, with a row of spots on each side of the spine, though, at the same time, I do not believe them to be distinct from the plain coloured or common brown variety, with which they perfectly agreed in every other respect. The subject is worth the attention of those who have an opportunity of settling the question. Three other species of the Axine group of deer are mentioned by Mr. Hodgson, under the collective name of Jarai, but individually distinguished by the Nepalese as the Phusro, Rato, and Kalo, or hoary, red, and black Jarais respectively. The two former have been identified with the *Corvus Hippelaphus* and *Cervus equinus* of Cuvier, the latter certainly without foundation, and the former at least very doubtful; the third, said to be undescribed, is probably the *C. Aristotelis* of Cuvier; but the truth is, that we know very little about them, nor are these different species mentioned by any other author besides Mr. Hodgson. The *Cervus Hippelaphus*, indeed, called *Saumer* or *Sambre* in the plains, is well known in England, where he has long existed in its menageries, and is probably the *C. Aristotelis*, which is familiarly called *Elk* in the Hills, and of which the native name in the British hill provinces is *Jerow* for the male, and *Maha* for the female, names which have been not unfrequently applied to different species: of the Phusro, or Hoary Jarai of Mr. Hodgson, which whatever else it may be, is certainly not the *C. equinus*, since that species does not inhabit Continental India, nothing is known but the name, if, indeed, it be not a mere variety of sex or age. Lieut. Smith describes the Jerow of the Hills as a larger and heavier animal, and with finer horns, than the Saumer of the Plains: the tan and black colours of these two species appears to identify them with the Rato and Kalo Jarais of Mr. Hodgson.

No fewer than three species of deer, with characters approaching to those of the common stag (*C. Elaphus*) of Europe, have been mentioned as inhabitants of Nepal. Two of these, the *Cervus Wallichii* and *Cervus Duvacellii* of Cuvier, are known, though not so perfectly as could be wished; the third, which has been identified with the common stag, appears to be founded upon error. Mr. Hodgson has briefly described the *Cervus Duvacellii* under the name of *C. Elaphoides*, and I have seen a full-grown male in the Zoological Gardens; the comparison of the skull figured by Mr. Hodgson with the horns in the *Ossements Fossiles* leaves no doubt as to the identity of the species. It is called in Nepal *baraiya*, and according to Mr. Hodgson, *Maha* in the Western Hills, a name which, as observed above, Lieut. Smith applies to the female Jerow. *Cervus Wallichii*, called *Barah Singha*, is mentioned by Mr. Walter as an inhabitant of the mountains of Silet and by Mr. Hodgson who confounds it

with the common stag, as found in the Saul Forest, which skirts the foot of the Nepal Mountains, whence it was originally sent to Calcutta by Dr. Wallich. There is no grounds for supposing the existence of a third species of this group in the Himalayas, identical with the Red Deer of Europe (*O. Elaphus*), though the fact is distinctly stated both by Duvaucel and Mr. Hodgson: these authors appear to have mistaken the *O. Wallichii* for that animal, though the specific distinction was afterwards well known to Duvaucel, who sent to Baron Cuvier the description published in the "Ossements Fossiles." Dr. Falconer mentions the discovery of a new species of deer in the Report of his recent Journey to Cashmere and Little Thibet, and Dr. Royle has figured (tab. 5, fig. 1) a female under the name of *O. Dodur*, by which it is known about Saharunpore. He describes it as being about the size of the female Hiru (*Antelope cervicapra*), lighter and more graceful than the Hog-deer, and of an ashy brown colour; but this is all I know of the animal, nor do I find it even mentioned by any other writer. It appears to be unquestionably a new species, and is well worth the attention of Indian naturalists.

Three distinct species of the Muntjac tribe of deer inhabit the Indian continent: one entirely black (*Cervus melas*), one of a light sandy fawn colour, probably the *Ratwa* of the Nepalese (*C. ratwa*, Hodg.), and the third the common Muntjac, called Kacker by the natives, and Barking Deer by the Europeans (*C. Muntjac*, Lin.), of a deeper bay and much smaller size than the *Ratwa*: the former is scarcely the size of the Roe-buck (*C. Capreolus*); the latter nearly equals the Fallow Deer (*C. Dama*, Lin.). Dr. Royle has figured the "Barking Deer" of the North Western Himalayas, v. tab. 5, fig. 2, under the name of *Cervus Ratwa*, conceiving it to be identical with Mr. Hodgson's species may be readily distinguished from the other species of Deer, by their long projecting tusks, horns mounted upon long bony pedicles, and the glandular folds of skin on the forehead. They require, however, to be more attentively examined, and compared with one another.

(1128) Of *Hollow-horned* Ruminants, the *Ghoral* and *Thar* (*Antelope Ghoral* and *A. Thar*), are now pretty well known from the researches by Mr. Hodgson. Both the species are proper to the middle and northern regions of the Hills. The *Thar* of Mr. Hodgson is universally called *Suroo* and *Imoo* in the more western parts of the mountains, the latter name predominating in the higher, and the former, in the lower hills: the name of *Thar*, according to Lieut. Smith, is there applied exclusively to the species of goat which Mr. Hodgson calls the *Jharal*. That beautiful and stately antelope, the *Chiru* (*A. Hodgsonii*), of which our knowledge is entirely due to Mr. Hodgson's researches, is confined to Bhot, Thi-

bet, and the surrounding countries; it appears to be altogether unknown on the southern face of the Mountains, except from an occasional specimen imported by the traders, either for presents or barter. The common Indian antelope, called *Hiru*, and the *Chickarra*, or four-horned species (*A. cervi*, *capra* and *quadricornis*), are confined to the lower hills and forests, and the *Neel-ghau* (*A. picta*) principally to the plains and jungles of the north-western districts. Mr. Colebrooke says that, in the opinion of the Hindoos, the resort of the Antelope sanctifies the countries graced by his presence, while his absence degrades the regions which he avoids. This seems more connected with physical observation than with popular prejudice. The wide and open range in which the Antelope delights is equally denied by the forests of the mountain and by the inundation of the fens. These are the only antelopes of which we have any precise knowledge, as inhabitants of this part of India; but it is probable that others still remain undescribed. Captain Herbert, in his "Tour to the Sutlej," mentions two animals by the names of *Skin* and *War*, the accounts of which do not agree with any known species, and which are therefore well worth the attention of future observers. The *War*, according to Capt. Herbert, is somewhat like the *Musk Deer* (*Moschus Moschiferus*), but with a face more like that of a sheep, divided hoofs, and horns more nearly resembling those of a buffalo than of any other animal; a description which, in spite of the similarity of names, is inapplicable either to the *Thar* or *Jharal*, though indeed, little dependence is to be placed in the descriptions of unscientific observers.

(1129) The *Neel-ghau* deserves a more particular notice, for the purpose of clearing up a point in its history, equally interesting to the Classical Scholar and to the Zoologist. It has been already observed that Modern Naturalists, after the example of Baron Cuvier, have identified the great *Saumer Deer* of India with the animal which Aristotle describes by the name of *Hippelaphus*. "The *Hippelaphus*," says the Greek philosopher, "has also a mane, (of the Horse), above the shoulders, but from this to the head along the top of the neck it is very thin: it has likewise a beard on the larynx...it is about the size of the Stag...the female has no horns...those of the male resemble the horns of the *Dorcus* (*A. Gazelle*)...it inhabits Arachosia. Any one acquainted with the *Neel-ghau* will readily perceive the applicability of this passage to its most obvious characters: In fact Aristotle's description of this animal, under the name of *Hippelaphus*, is more exact and minute than the description of any other animal mentioned in his history; it is evidently taken from personal observation, and it is surprising that the application should have hitherto escaped the penetration both of critics and Zoologists. The older natu-

ralists, such as Gesner and Aldrovandus may be excused for misapplying the passage in question, sometimes to the Elk, sometimes to the common Stag in his winter-dress, when the hair of the neck becomes longer than ordinary, since they were unacquainted with the form and characters of the Neel-ghau; but the continuation of the mistake by their successors, to whom the animal has been long familiar, is altogether unpardonable. This identification, indeed, was absurd enough from the beginning: the habitat of Arachosia, and the assigned form of the horns, were alone sufficient to distinguish the Hippelaphus from either the Elk or common Stag, independently of the critical absurdity of supposing Aristotle to describe such well-known animals at such length and under a new name: but the truth is, that all modern commentators have been misled by a wrong translation of the term *Δορκας* employed by Aristotle, as the name of an animal, to the horns of which he compares those of the Hippelaphus. Now, it is to be observed that the Dorcas of the Greeks and Romans is universally admitted to be the Gazelle of Egypt and Northern Africa, as may be easily proved from many passages in Herodotus and other ancient writers. Theodore Gaza, himself a Greek, and the first translator of Aristotle, very properly renders the word by *capra*, but Buffon having criticised Gaza's ignorance, and affirmed that the word should really be translated *caprea*, every body has since followed the translation of Buffon, and the Dorcas of Aristotle has been accordingly considered identical with the Roe-buck, whilst the Dorcas of all other ancient writers is acknowledged to be the Gazelle.

This seems to have been one of the principal sources of error which misled Baron Cuvier, after the example of his predecessors, to identify the Hippelaphus of Aristotle with a species of Deer. The head and skin of the large Indian Saumer had been sent to Paris by Diard and Duvaucel; the hair of the neck was observed to be considerably longer and coarser than that on the rest of the body, the horns had only two antlers, like those of the Roe-buck, and it came from India. Baron Cuvier immediately concluded that he had discovered the real Hippelaphus of Aristotle, and taken considerable pains to prove it. Oss. Foss. IV, 42. Against this opinion of the most distinguished of modern naturalists, however, I have to urge objections as grave as those which lay against the ancient error which identified the Hippelaphus with the stag and elk. In the first place, as I have just shown, the fancied similarity of the horns of the Hippelaphus to those of the Roe-buck, arises from a false translation of the word Dorcas; when this term is properly translated, Gazelle, the horns of the Hippelaphus, to be similar to those of the Dorcas, should be small, round, and without branches;—such are the horns of the Neel-ghau, and

such are not the horns of the Saumer. In the second place, the Saumer Deer has certainly longer and stiffer hair on the neck than elsewhere, but it is equally long and rough over the whole neck, as well on the sides as above and below, and has no resemblance whatever to the mane of the horse and mule to which Aristotle compares it. In fact the description of Aristotle does not apply to it in any particular. The Saumer does not show the least appearance of the thin mane along the top of the neck, longest and thickest on the shoulders; neither has it anything that can be called a beard, distinct, at least from the general roughness of the neck which Baron Cuvier calls its mane. But even allowing the rough hair on the under surface to be called a beard; still Aristotle's description does not apply, for this rough hair covers the whole throat in the Saumer from the head to the chest, whilst the Greek philosopher restricts the beard of the Hippelaphus to the *κάρυνξ*, and this is precisely the situation in which the long bunch of coarse hair, nearly a foot in length, is found on the throat of the Neel-ghau. In fact there is not a single point, even to the most minute particular, the habitat of Arachosia, for instance, the modern Punjab, where the Neel-ghau is extremely abundant, and where the Saumer does not exist, at least we have no evidence of the fact,—in which Aristotle's description of the Hippelaphus does not perfectly agree with this now well known animal; and we may therefore safely conclude that we have at length finally settled a question which has long puzzled both critics and Zoologists. The Neel-ghau should consequently assume in future the specific appellation of *Antelope Hippelaphus*, whilst the Saumer Deer, to which that name has been erroneously applied may be more appropriately called *Cervus Saumer*.

(1130) *Capra*. Two distinct species of the genus *Capra* occur in the Himalayas: *Capra jemblaica* of Hamilton Smith, called *Jharal* in Nepal, and *Thar* in the British provinces, is by far the more common of the two, and is stated by Mr. Hodgson to differ from other goats by having four teats. The second species has never been described, but its existence is placed beyond a doubt; Major Kennedy, while resident at Simla, had two stuffed specimens, procured in the neighbouring mountains, and the animal is mentioned by various tourists under the name of the Ibex, which it appears to resemble in the form of the horns and other characters. Dr. Falconer, in the Report of his late Journey to Cashmere and Little Thibet, mentions the discovery of two new species of goats; but as he does not enter into any detail on the subject, we have no means of ascertaining how far they may prove to be identical with or different from, the two species here mentioned. Different varieties of the domestic goat the most valuable of which are the Changra, or shawl goats, of two breeds, distinguished as

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

the longer and the smaller Changra, are found in the more alpine regions; their wool forms an article of extensive traffic, but we are much in want of detailed comparative descriptions and good figures of these, as of all the different breeds of cattle and other domestic animals in India; a subject of great interest, which has been extensively illustrated at home, but which has met with little or no attention out of Europe.

(1131) *Ovis*. There are likewise two wild species of sheep and numerous domestic varieties, found in the Himalayas. The *Burrhal* called *Nahoor* by the Nepalese (*Ovis Nahoor* of Mr. Hodgson), is intermediate in character between the Mouflon (*O. Musmon*) of Corsica, the supposed parent of our domestic sheep, and the Aoudad (*O. tragelaphus*) of Northern Africa, which latter species it resembles in the form of the horns and the absence of the crumens, or tear-pits, which distinguish the rest of the genus. The second species, called *Banbhera* in Nepal, is less known, but appears to approach very nearly to the Argali of Siberia (*O. Ammon*), if, indeed, it be not identical with that animal: the skull and horns are in the Museum of the Royal Asiatic Society, to which it was presented by Sir Alexander Burnes; but as there is no specimen of the Argali in this country with which to compare it, no opinion can be offered as to its specific difference. The animal seems to be more properly a native of Thibet and Chinese Tartary, and seldom appears on the southern part of the Himalayas; at least sportsmen had never met with it, and Mr. Hodgson was long doubtful of its existence. Of the domestic sheep of the Hills, besides the Dumba, or common variety of Upper India, Mr. Hodgson mentions a breed called *Barwall* as occurring in the Kachar, and another called *Hoaniah*, peculiar to Thibet: these are used as beasts of burthen.

(1132) *Bovidae*. Of the genus *Bos*, the buffalo (*B. Bubalus*), and its representative, the *Arnee*, *Bos Bhinse*, are confined to the sultry forests at the foot of the mountains. The latter is a very distinct variety, if not a different species, from the *Jungle Bhinse* of Bengal and Assam, so well known for the great length of its horns; the *Arnee* of the Saul forest is the short thick horned variety, of which there are many skulls, preserved in our Museums, and is said to be a much lighter made animal, though with a thicker skin than the *Jungle Bhinse*.

(1133) The *Zebu* (*Bos indicus*) is common in every part of the Hills; but the peculiar and appropriate species of the Himalayas is the Changree, or Yak (*Bos pæphagnus*, Pallas), which composes the domestic cattle of Tartary, and is not uncommon on the southern slopes of the higher Mountains, where a cross between it and the Zebu, or common Indian Ox, is much used in agriculture, and preferred to either of the pure races. This hybrid is not uncommon at Simla

and it is to be hoped that some intelligent observer will take advantage of this circumstance to ascertain from actual experiments whether the sexes be productive *inter se* or when united with one of the pure races; or whether, like the common mule, they be absolutely barren. Lient. Smith informs that he has seen the Yak wild on the confines of Chinese Tartary.—*Ogilby in Royle's Illustrations of the Botany, &c. of the Himalayan Mountains, Supplementary Patr.*—Quoted in and extracted from *Madras Lit. Soc. Journal* for 1840.

(1133b.) MAMMALIA OF MALAYAN PENINSULA AND ISLANDS. Dr. Theodore Cantor gives the following:—The Localities printed in Italics signify those from whence the animals of the Catalogue were obtained; in ordinary type those previously given by authors.

*Hylobates leuciscus*, apud Cantor Ann. and Mag. of Nat. Hist.

“Ungka puti” and “Wow-wow” of the Malays of the Peninsula.

The colour varies from blackish-brown, to light-brown, yellowish or dirty-white, sometimes uniform, sometimes mottled. The index and middle toes, of both or of one foot, are in some individuals, of whatever sex or shade of colour, united by a broad web throughout the whole of the first phalanx: in some partially so, and in others, not. The ribs vary from twelve ( $7 \times 5$ ) to thirteen pairs ( $7 \times 6$ ), as observed by Mr. Blyth. —(*Journal. Asiatic Society* 1841, Vol. X. page, 839.

(1133e.) *HYLOBATES AGILIS*, F. Cuvier.

*Var. Ungka etam*, Martin.

SYN.—Ungka etam, Raffles.

Oungka, *Hylobates Lar*, F. Cuv.

*Simia Lar*, Vigors and Horsfield.

*Hylobates Rafflesii*, Geoff, apud Ogilby.

*Hylobates variegatus*, Muller apud Schinz.\*

“Ungka etam”, of the Malays of the Peninsula.

\* Schinz gives as a synonyme: *Pithecus variegatus*, Geoff. which, however, is *Hylobates Lar*, Var.

HAB.—*Malayan Peninsula*, (*Malacca, Purlis, Keddah, Pungah*) Sumatra.

The first phalanges of the index and middle toe are in some individuals of either sex, partially or entirely united by a web. Sometimes the first phalanx of the middle toe is partially united to the fourth.

An adult male examined, had thirteen pair of ribs ( $6 \times 7$ ), an adult female fourteen ( $7 \times 7$ ), a young male on the left side thirteen ( $7 \times 6$ ), on the right twelve ( $7 \times 5$ ). In these three individuals the stomach was constricted at the fundus and the pyloric part, which characters, when compared with specimens of *Hylobates agilis* from Sumatra, will go far to decide the identity of that species and *H. Rafflesii*. On the Malayan Peninsula, the latter appears to be less numerous than *H. Lar*. The light-coloured Var. of *H. agilis* I have not seen.

*Semnopithecus obscurus*, apud Martin.

*Presbytes obscura*, Gray, List of Mamm. B. M.

*Semnopithecus sumatranus*, Muller, apud Schinz ‡

*Semnopithecus halonifer*, Cantor, proceed. Linn. Soc.

“Lotong” or “Lotong clam,” of the Malays of the Peninsula.

† The Hab. Pinang and Singapore, in neither of which islands *Semnopithecus femoralis* appears to occur, tends to prove, that Sir S. Raffles did not, as it has been supposed, refer to that species. His short description indicates *S. obscurus* (Lotong,) the most common species in both islands. Sir S. Raffles evidently did not describe the living animal, or he would not have omitted one of the most striking characters, viz., the white marks of the face, which, in preserved specimens, become obliterated, so that the face appears uniformly black. The omission of this character by Sir S. Raffles, and subsequently by later describers of this species, has given rise to confusion.

‡ Schinz repeats *S. femoralis*, Martin, as a Syn. for *S. sumatranus*, and says in a note, that Muller in his monograph of *Semnopithecus* refers that species to his *S. sumatranus* (Schinz Syn. Mam. 1. p. 31, note.) Were even the two identical, the species should not have been renamed, as *S. femoralis*, Horsfield, not Martin, would take precedence, being the denomination under which Dr. Horsfield described it in the Appendix to the Life of Sir. T. Stamford Raffles, 1830.

HAB.—*Malayan Peninsula, Pinang, Singapore.* District adjacent to Singapore, in the Malayan Peninsula.

(1133h.) *SEMNOPITHECUS ALBOCINEREUS*, Schinz.

SYN.—*Cercopithecus albocinereus*, Desmarest.

Ka-ka of the Malays of the Peninsula.

\* Martin, p. 581, refers the young *S. dorsatus*

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

to *S. femoralis*, but the description is that of the young of the present species.

HAB.—*Malayan Peninsula*.

The young of this species, described by Martin, p. 481, is from the peculiar distribution of the colours, as easily distinguished from the young of *S. obscurus*, as it is difficult to distinguish the adults of these two species. Both attain to the same size, have in common the shape of the body, the white marks of the face, and the general distribution of colours. In the adult of the present species the prevailing colours are clear ashy-grey above, and white below. On either parietal bone, the hairs form a whorl, and the anterior are directed forward, projecting beyond the eyebrows. The two whorls are distinct in the young, though the hairs of the head are too short to mingle with the long, erect, divergent, black hairs of the eyebrows. Just below the spot where the two whorls come in contact, the skull is naked, thus forming a rather broad, triangular forehead. The general colour of *S. obscurus*, both in the young and adult state, is considerably darker. On the upper parts a blackish, or brownish ash colour prevails, lighter below, which acquires in some individuals a whitish appearance, from the white skin of the stomach, which is but scantily covered with hairs. Of parietal whorls there is no trace; the hairs of the head, directed backwards, originate in a peak as far down as the glabella, and are smoothed down on the top of the head from the occipital crest backward.

(1133i.) SEMNOPITHECUS CRISTATUS, Horsfield.

SYN.—*Simia cristata*, Chingkau, Raffles.

*Semnopithecus pruinus*, Desmarest.

*Semnopithecus pruinus*, apud Lesson.

\* Gray quotes *S. maurus*, Horsfield, and Schinz *S. femoralis*, Martin, as synonyms, both of which are species, in physiognomy, colours, and, as far as *S. maurus* is concerned, in habits distinctly different from the present one.

HAB.—*Pinang, Malayan Peninsula*. Sumatra, Borneo, Banka.

The whitish colour round the eyes and the mouth is present, though less distinct in the this than in the preceding two species.

(1133j.) SEMNOPITHECUS FEMORALIS, Horsfield.

SYN.—*Semnopithecus chrysomelas*, Muller, apud Martin and Schinz.

HAB.—*Purlis (on the Malayan Peninsula)*. Borneo Java (?), Sumatra (?)

In a young male of this, apparently every where difficultly procurable species, the face during life was intense black, except the white-haired lips and the chin, which were of a milk-white colour. In the preserved specimen, the latter soon changed into the dull brownish-black of the

rest of the face. The interdigital membrane, often loosely connecting the first phalanges of the four fingers and toes in *S. obscurus*, albocineus, cristatus and other Malayan monkeys, was also present in this individual, in which even the first and second phalanges of the index and middle toe were thus connected. In preserved specimens, the interdigital web becomes shrivelled and indistinct, and therefore, being at all times a very questionable, if not altogether inadmissible, specific character, ought in such state to be least relied upon. On its arrival at Pinang, the animal was in too sickly a state to allow of its natural habits being observed.

GEN.—CERCOPITHECUS, apud Ogilby.

HAB.—*Pinang, Malayan Peninsula*, Java, Siam, Tenasserim, Arracan, Bengal, Sylhet, Assam.

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

The sublingual appendage is cartilaginous, of a white colour; the apex divided in a number of fine points. The new-born is of the same colour as the adult, but paler, and has the dense, soft fur, mixed with a number of long hairs, grey at the base, white at the point. In a male, measuring from the apex of the nose to the root of the tail one foot two and a half inches, the tail five-eighths of an inch, the dimensions of the intestinal canal, were:

Small Intestines,..... 3 feet  $\frac{1}{2}$  inches.

Large ditto,..... 2 „  $3\frac{1}{2}$  „

Cæcum,..... 0 „  $3\frac{1}{2}$  „

GEN.—GALEOPITHECUS, *Pallas*.

(1133n.) GALEOPITHECUS TEMMINCKII, Waterhouse.

SYN.—Lemur volans, Linn. apud Marsden and Raffles.

“Kubong” or “Kurbong” of the Malays of the Peninsula.

HAB.—Singapore, Pinang, and other Islands in the Straits of Malacca. Luncavy Islands Malay Peninsula. Java, Sumatra, Borneo, Pelew Islands, Siam.

Two individuals are never of precisely the same design and ground-colour, which latter varies from clear ashy-grey to greyish-brown or chesnut. The white spots on the back of the anterior extremities, appear to be constant in every age. Though there are four mammæ, situated in pairs one above the other, close to the axilla, of a number of females with young, none had more than one offspring, which was carried wrapped in the wide mantle-like membrane. In several shot on the hills at Pinang, the stomach contained vegetable matter, but no remains of insects. In confinement, plantains constitute the favourite food, but deprived of liberty the animal soon pines and dies. The anterior margin of the broad smooth tongue has a fringed appearance, produced by a number of rounded papillæ. In a male measuring from the apex of the nose to the root of the tail one foot four inches, the tail nine inches, the intestinal canal was of the following dimensions:

Small Intestines,..... 4 feet 4 inches

Large do ..... 7 „ 7 „

Cæcum,..... 0 „ 11 „

Costæ veræ seven pairs, spuræ six pairs.

Molosse grele, Temminck.

Dysopes tenuis, Schinz.

HAB.—Malayan Peninsula. Java, Sumatra, Borneo.

Two individuals had the back of a velvety snuff colour, becoming a shade lighter on the underparts. Entire length of the larger four and four-eighth inches, of which the tail one and two-fourth inches. Extent of the flying membrane ten and four-eighth inches. In the size of the ears some difference exists in the two.

GEN.—TAPHOZOUS, *Geoffroy*.

(1133r.) TAPHOZOUS MELANOPOGON, Temminck.

SYN.—Taphozous melanopogon, apud Schinz.

HAB.—Pulo-Tikus, Pulo-Lancavy, Malayan Peninsula. Java, Caves of Kanneria.

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

Temminck's description, as quoted by Schinz, is taken from the adult male, the Malayan individuals of which differ in having the black beard surrounded by a broad light-brown band, covering, like a pelerine, the chest and shoulders. The rest of the lower parts are either white or brownish-white. The flying membrane in the adult male is whitish; in the females and young males it is blackish or brownish between the legs, along the sides of the body and the arms. The colour of the female and young male is on the back of a more or less brownish mouse-grey, becoming much lighter or whitish beneath, but both are destitute of the black beard, which, out of a number of between forty and fifty from different Malayan localities, occurred but in seven males, although some of the beardless males in size and extent of flying membrane equalled, or even slightly exceeded, the bearded. The entire length of the largest male was four inches, of which the tail measured one inch.

Extent of flying membrane fifteen and four-eighth inches.

0	1—1	4-4
Incis.—	Canin.—	Molar,—
4	1—1	5-5

(1133s.) *TAPHOZOUS SACCOLAIMUS*, Temminck.

SYN.—*Taphozous pulcher*, Elliot MSS. apud Blyth.

HAB.—*Pinang*. Java, Sumatra, Borneo, Celebes, Southern India.

In two males captured at Pinang in houses in the valley, the colours somewhat differ from Temminck's description, quoted by Schinz. In the larger, the head and back are of a sooty black, with a few white dashes, the lower parts of a pure white. The flying membrane is black between the legs, along the sides of the body and the arms, and between the index, second and third fingers; the rest being dull semi-transparent white. The length from the apex of the nose to the posterior margin of the inter-femoral margin, is four and seven-eighth inches, of which the tail measures one inch. The extent of the flying membrane eighteen inches. Dentition as in *T. melanopogon*. The smaller differs in having the chest of a pale brownish-white, the abdomen and the pubes light rust-coloured, leaving the sides pure white. Mr. Blyth quotes *Taphozous pulcher*, Elliot, from Southern India, as being, "black-brown above with white pencillings, and pure white below," (Journal As. Soc. xiii. 1844. p. 492,) from which, as well as from Mr. Elliot's specimen, at present in the Museum of the Asiatic Society, it appears that the Indian more resemble the Malayan individuals than those of the Indian Archipelago, described by Temminck. The internal surface of the gular sac secretes an odorous oily fluid, of a light brown colour.

GEN.—*RHINOLOPHUS*, Geoffroy.

*RHINOLOPHUS*, Gray.

(1133t.) *RHINOLOPHUS AFFINIS*, Horsfield.

(1133u.) *HIPPOSIDEROS DIADEMA*, Gray?

SYN.—*Rhinolophus Diadema*, Geoffroy?

HAB.—*Pinang*, *Malayan Peninsula*. Timor.

The Malayan individuals are, according to age and sex, of a more or less intense reddish or greyish-brown above, under certain lights assuming a golden lustre, owing to the whitish points of the hairs; beneath, they are of a lighter greyish-brown. Individuals occur of a light golden-brown, in colours resembling *Rhinolophus larvatus*, Horsfield. In the adult male, the livid flesh-coloured nasal appendage is larger, more complicated, and somewhat different from the figure given by Geoffroy St. Hilaire, (Ann. du Museum XX, Pl 5 and 6), which resembles the female in the simpler appendage and in the absence of the frontal pore. The latter organ, in the adult male, is large, secreting a yellowish brown oily fluid, the odour of which resembles that of *Arctictis Binturong*, Fisher. A female, during lactation, presented a great inequality in the development of the inguinal warts, of which the right measured one-quarter of an inch in length. At the time of her capture, it was reported that a young one had been "sucking" the right wart. Not having myself observed the young clinging to that organ, I cannot vouch for the correctness of a statement which, if authentic, would tend to explain the use, being to afford support to the young, when not sucking. The size of the Malayan individuals appears to exceed those from Timor, the entire length of the former being five and six-eighth inches, of which the tail measures two inches. Extent of the flying membrane twenty-one and a half to twenty-two inches. The extremity of the 2nd phalanx of the fourth and fifth fingers is bifid, or terminating with two minute diverging joints, a structure also existing in the Malayan individuals of the following species.

2 1—1 5-5

4 1—1 5-5

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

(1133f.) *HIPPOSIDEROS NOBILIS*, Gray.

SYN.—*Rhinolophus nobilis*, Horsfield.

*Rhinolophus nobilis*, apud Fisher.

*Rhinolophe fameux*, Temminck.

*Rhinolophus nobilis*, apud Schinz.

HAB.—*Pinang*, *Malayan Peninsula*. Java, Sumatra, Timor, Amboyna.

The frontal pore is less developed than in the former species, as compared with which the present is of a more slender form, though of a size little less inferior. Entire length five and four-eighth inches, of which the tail measures two and one-eighth inches. Extent of flying membrane twenty-one and four eighth inches. Dentition similar to that of *H. Diadema*. In the valley of Pinang single individuals of both species are at night abroad at all seasons, but during the rains they are particularly numerous.

(1133w.) *HIPPOSIDEROS VULGARIS*, Gray.

SYN.—*Rhinolophus vulgaris*, Horsfield.

*Rhinolophus insignis*, Var. apud Temminck.

*Rhinolophus insignis*, Horsfield apud Schinz.

*Rhinolophus vulgaris*, Horsfield *female of insignis*, apud Schinz.\*

HAB.—*Pinang*. Java.

\* The only individual of *Rhinolophus vulgaris*, Horsfield, observed at Pinang, happened to be a male.

Entire length four inches, of which the tail measures one and three-eighth ; extent of flying membrane fourteen inches.

2	1—1	4-4
Incis.—Canin.	—	Molar, —
4	1—1	5-5

(1133x.) *HIPPOSIDEROS MURINUS*, Gray.

SYN.—*Rhinolophus murinus*, Elliot.

HAB.—*Pinang*. Southern Mahratta Country, Nicobar Islands.

Entire length two and four-eighth inches, of which the tail measures one inch. Extent of flying membrane nine and four-eighth inches. Dentition similar to that of the last species.

*B. Forehead simple.*

(1133y.) *HIPPOSIDEROS GALERITUS*, N. S.

*H. prosthematis simplicis membrana transversa lata, alte erecta, auriculas tangente ; auricularum, late pyriformium, apicibus lacinia exsertis, besse postico lobuloque basali villosis ; vellere longo, denso, molli, bicolore ; supra saturate, subtus pallidius-fusco-rufescenti.*  
Latet fœmina.

HAB.—*Pinang*.

Entire length three inches, of which the tail measures one inch. Extent of the flying membrane ten and four-eighth inches.

2	1—1	4-4
Incis. — Canin. —	—	Mol. —
4	1—1	5-5

The livid flesh coloured nasal appendage is simple but large, occupying the whole upper part

of the face and the forehead ; the horse-shoe or nasal disk covers the short, rounded, hairy muzzle, which has two leaves on either side ; the transversal membrane is concave, as broad and long as the horizontal horse-shoe, which it joins under a right angle, while its sides are almost in contact with the ears. The latter are sub-erect, broader than long, their breadth equalling the length of the head ; the shape is broad, pyriform, narrowing towards the apex, which appears like a small artificially rounded flap, scarcely elevated above the level of the fur covering the vertex. More than two-thirds of the back of the ear is covered with fur, leaving a narrow naked line along the external margin, which, as well as the singular shape of the ear itself, affords a distinguishing character. The hairs are buff or whitish at the base, the other half of their length brown. The general colour of the upper parts is deep-brown, with a slight reddish hue, becoming a shade lighter beneath.

This species somewhat resembles *Hipposideros apiculatus*, Gray (*Vespertilio speoris*, Schneider, apud Schreber ; *Rhinolophus speoris*, Geoffroy,) from which it however differs in the absence of the frontal pore, in the shape of the ears, and in colours. A solitary male was captured in the valley of Pinang.

GEN.—*VESPERTILIO*, Linne.

(1133z.) *VESPERTILIO*, Gray.

*VESPERTILIO ADVERSUS*, Horsfield?

SYN.—*Vespertilio adversus*, Fisher?

*Vespertilio adversus*, Temminck?

*Vespertilio cineraceus*, Blyth, MSS.

HAB.—*Pinang*. Java, Calcutta.

This bat having the characteristic distinction of the upper incisor, described by Horsfield, is above greyish-brown, beneath light-greyish, measuring in length three and two-eighth inches, of which the tail is one and four-eighth inch. Extent of flying membrane ten and four-eighth inches. It differs from *V. adversus* in having on each side five molars, of which but two are spurious, which character also obtains in *V. cineraceus*, Blyth MSS. and specimen in the Museum Asiatic Society, which (as observed by Mr. Blyth,) as well as the present, may prove varieties of *V. adversus*, Horsfield.

*KIRIVOULA*, Gray.

(1133a.) *KIRIVOULA PICTA*, Gray.

SYN.—*Vespertilio ternatanus*, Seba?

*Vespertilio pictus*, Pallas, apud Horsfield.

*Vespertilio kerivoula*, Boddaert.

*Vespertilio kerivoula*, apud Geoffroy.

HAB.—*Pinang*. Java, Sumatra, Borneo, Ceylon.

(1133b.) *KIRIVOULA TENUIS*, Gray.

SYN.—*Vespertilio tenuis*, Temminck, apud Schinz.

HAB.—*Pinang*. Java, Sumatra, Borneo.

A single male, in colours slightly differing from Temminck's, being above of a dark greyish-brown, many of the hairs with white points ; beneath of

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

a lighter shade. Entire length three and two-fourth inches, of which the tail one and four-eighth inch. Extent of flying membrane ten inches.

## TRILATITUS, Gray.

(1133c.) *TRILATITUS HORSFIELDII*, Gray.

SYN.—*Vespertilio tralatitius*, Horsfield.

*Vespertilio Gartneri*, Kuhl, apud Schinz.

HAB.—*Pinang*. Java, Sumatra.

*SCOTOPHILUS*, Leach apud Gray.

(1133d.) *SCOTOPHILUS TEMMINCKII*, Gray.

SYN.—*Vespertilio Temminckii*, Horsfield.

*Vespertilio Belangerii*, Isid. Geoff.

*Vespertilio noctulinus*, Isid. Geoff.

*Scotophilus castaneus*, Gray.

*Nycticeius Temminckii*, Schinz.

*Nycticeius Belangerii*, Temminck, apud Schinz.

*Nycticeius noctulinus*, Temminck, apud Schinz.

“Klawah” of the Malays of the Peninsula.

HAB.—*Singapore, Pinang, Malayan Peninsula and Islands*. Java, Sumatra, Borneo, Timor, Pondicherry, Calcutta.

As observed by Schinz, this species is very variable in its colours according to age, all of which variations occur in individuals inhabiting Pinang and the Malayan Peninsula. The following are the specific names attributed to different individuals of this species:—

1. *Vespertilio Temminckii*, as originally described and figured in *Zoological Researches in Java*. Back dark-brown; greyish-brown underneath. Entire length four inches six lin., of which the tail one five-eighth of an inch; extent of flying membrane twelve inches.

2. *Scotophilus castaneus*, Gray.

3. *Nycticeius Belangeri*, Temminck, apud Schinz. Hairs of the back brown at the base, chesnut or olive-chesnut at the apex; beneath light yellowish-brown, isabella or whitish. Entire length 3½” of which the tail 1” 11” extent of flying membrane 13.”

	1-1	1-1	4-4
Incis.	—	Canin. —	Mol. —
	6	1-1	5-5

4. *Nycticeius noctulinus*, Temminck, apud Schinz, is the very young. Above more or less intense brown or rust-coloured; beneath isabella or light greyish-brown. Entire length three to three two-eighth inches, of which the tail seven-eighth to one two-eighth of an inch. Extent of flying membrane eight six-eighth to nine inches. In this state it has frequently been observed clinging to the mother.

	2-2	1-1	4-4
Incis.	—	Canin. —	Mol. —

This species is exceedingly numerous, forming large congregations in sheltered situations on the Malayan Peninsula, and in the caves on the numerous islands of limestone which stud the shores from Maulmein to Java, and in such localities large deposits of Guana occur. The latter, (“Ty Klawah” of the Malays, i. e. bats’ manure,) has been tried by agriculturists at Pinang, but has been found much less efficacious than the Guana obtained from the swift (*Collocalia*), producing the edible nests.

## FRUGIVORA.

GEN.—*PTEROPUS*, Brisson.

(1133e.) *PTEROPUS EDULIS*, Geoffroy.

SYN.—*Pteropus javanicus*, Desm. apud Horsfield.

*Pteropus Edwardsii*, Geoffroy.

“Kalong” of the Javanese.

“Kluang” of the Malays of the Peninsula.

HAB.—*Pinang, Singapore, Malayan Peninsula and Islands*. Java, Sumatra, Banda, Bengal. Assam.

GEN.—*CYNOPTERUS*, Fred. Cuvier.

(1133f.) *CYNOPTERUS MARGINATUS*, F. Cuv.

SYN.—*Vespertilio marginatus*, Buchanan Hamilton, MSS.

*Pteropus marginatus* Geoffroy.

*Pteropus titthæcheilus*, Temm.

*Pachysoma titthæcheilus*, Temm.

*Pachysoma brevicaudatum*, Is. Geoff.

*Pteropus brevicaudatus*, Schinz.

*Pachysoma Diardii*, Isid. Geoff.

*Pteropus Diardii*, Schinz.

*Pachysoma Duvaucellii*, Is. Geoff.

*Pteropus pyrivorus*, Hodgson, apud Gray.

HAB.—*Singapore, Pinang, Malayan Peninsula and Islands*. Java, Sumatra, Southern Mahratta Country, Bengal, Nipal.

The colour is very variable, not only individually, but according to age and sex, which has given rise to several supposed distinct species. But they all resemble each other in habits and dentition, they occupy one common place of rest, and their new-born, or very young, are of a uniform colour. The ears of the adult are, in all more or less distinctly margined with white.

1. *Cynopterus marginatus*. Back reddish, or brownish-grey; lighter underneath.

2. *Pachysoma titthæcheilus*.

3. *Pteropus brevicaudatus*. Male: back reddish or olive-brown; a tuft of hair on the sides of the neck, the chest, and the sides of the greyish abdomen rusty, or orange-coloured. Female: above yellowish, or greyish-brown; beneath lighter. In some individuals from Malacca, the flying membrane is of a light reddish-brown.

4. *Pachysoma Diardii*: Back greyish-brown; abdomen greyish, brown on the sides.

5. *Pachysoma Duvaucellii*: pale greyish brown.

The following is a description of a new-born.

the back and the posterior surface of the humerus and femur, were covered with dense, soft, short hairs, of a dark greyish-brown; all the rest of the body was naked, of a greyish-black colour. The eyelids were not yet separated. The joints of the bones of the extremities were cartilaginous. The nails of the thumb and index were developed, but the feet and nails of the toes had already attained the size of the adult. The tongue was considerably extensile. The teeth present were:

4	1—1	2-2
Incis. —	Canin. —	Mol. —
4	1—1	2-2

Entire length, one and four-eighth of an inch, of which the lightly projecting tail two-eighth inch. Extent of the flying membrane, six and four-eighth inches.

In an individual measuring two and four-eighth inches in length, with an extent of the membrane of nine inches, the face and the lower parts, excepting the throat, had become scantily covered with light brownish-grey, short hairs. The eyelids were separated. The shoulder, elbow, hip, and knee joints, had become ossified, the other joints still remaining cartilaginous.

#### INSECTIVORA.

GEN.—TUPAIA, *Raffles*.

(1133g.) TUPAIA FERRUGINEA, *Raffles*.

SYN.—“Tupai Press,” *Raffles* and *Horsfield*.

*Cladobates ferrugineus*, F. Cuv. apud *Schinz*.

*Sorex Glis*, *Diard* and *Duvaucel*.

*Glisorex ferruginea*, *Desmarest*.

*Hylogale ferruginea*, *Temminck*.

*Herpestes*, *Calcutta Journ. Nat. Hist.\**

\* Vol. II, p. 458, Pl. XIII½. The explanation accompanying this figure is as follows: “Searching for Col. Farquhar’s drawing of *Rhizomys Sumatrensis* already referred to, I found in the Society a drawing of a bushy-tailed *Herpestes*, differing nearly from Mr. Hodgson’s *Gulo Urva*, in having the tail of one uniform colour with the body, without the yellow tip. There is no name or letter on the drawing to shew from whence it came, and to prevent its following the fate of Colonel Farquhar’s *Rhizomys*. This is however incorrect. Pl. XIII½ represents no *Herpestes*: the elongated muzzle, the proximity of the large eye to the ear, which is exposed, and not hidden by the hairs of the cheek, are characters foreign to every known species of *Herpestes*. The draughtsman has very correctly represented a *Tupaia*, and the drawing, reappearing as a *Herpestes* in the *Calcutta Journal of Natural History*, has, by Mr. Blyth, been traced to be the original of Pl. IX, *Asiatic Researches*, Vol. XIV, where it properly accompanies the description of *Sorex Glis*, (i. e. *Tupaia ferruginea*) of M. M. *Diard* and *Duvaucel*.

“Tupai tana” of the Malays of Pinang.

HAB.—Pinang, Singapore, Malayan Peninsula. Sumatra, Java, Borneo.

The young of this very numerous species in hilly jungle, is easily tamed, and becomes familiar with its feeder, though towards strangers it retains its original mistrust, which in mature age is scarcely reclaimable. In a state of nature it lives singly or in pairs, fiercely attacking intruders of its own species. When several are confined together, they fight each other, or jointly attack and destroy the weakest. The natural food is mixed insectivorous and frugivorous. In confinement, individuals may be fed exclusively on either, though preference is evinced for insects; and eggs, fish, and earth-worms, are equally relished. A short peculiar tremulous whistling sound, often heard by calls and answers, in the Malayan jungle, marks their pleasurable emotions, as for instance, on the appearance of food, while the contrary is expressed by shrill protracted cries. Their disposition is very restless, and their great agility enables them to perform the most extraordinary bounds in all directions, in which exercise they spend the day, till night sends them to sleep in their rudely constructed lairs in the highest branches of trees. At times they will sit on their haunches, holding their food between the fore-legs, and after feeding, they smooth the head and face with both fore-paws, and lick the lips and palms. They are also fond of water, both to drink and to bathe in. The female usually produces one young; she has four mammae, the anterior pair of which is situated on the lower lateral part of the chest, the posterior on the side of the abdomen. On the lower surface of the tongue, the frenum is continued to within a short distance of the apex in a raised line, on either side of which the skin is thickened, fringed at the edges, and thus presenting a rudimentary sublingual appendage, somewhat similar to that observed in *Nycticebus tardigradus*; though in *Tupaia ferruginea* the fringes of the margin only are free, the rest being attached to the tongue, but easily detached by a knife. The lateral raised lines of the palms and soles, the posterior part of the first phalanges, and the third phalanx (second of the thumbs,) which is widened into a small soft disk, in fact all the points which rest upon the ground, are studded with little transversely curved ridges or duplicatures, similar to those observed under the toes, of some of the *Gekkotidae*, which fully account for the precision, the ‘aplomb,’ with which these animals perform the astounding leaps from below, barely touching with the soles the point d’appui above. In a cage, the Tupai will continue for hours vaulting from below, back downwards, poise itself for an instant, continuing back downwards under the horizontal roof, and regain the point of starting, and thus describe a circle—the diameter of which may be three to four times the length of the animal,—in far shorter time than is required for the description. In a young male, measuring from the nose to the

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

root of the tail seven and three-fourth inches, the tail six and a half inches, the dimensions of the intestinal canal were :

Small Intestines, 3 ft.  $4\frac{1}{2}$  inch., diameter  $\frac{1}{8}$  inch.  
Large ditto,..... 0 „  $3\frac{3}{4}$  „ „  $\frac{1}{3}$  „  
Cæcum,..... 0 „  $0\frac{3}{4}$  „ „  $\frac{1}{16}$  „  
Costæ veræ : 8 pairs ; spuræi : 5 pairs = 13 pairs.

This species\* is infested with a tick of the following description : *Ixodes Tupaiæ*. Body suboval, shining dark-green olive ; scaly plate, palpi casing the pointed sucker, and the legs : pale reddish-brown. Length, when -wollen, three-eighth inch.

\* Single light coloured individuals of this species occur with the back, limbs and abdomen greyish, whitish, or isabella.

GEN.—GYMNURA, *Raffles*.

(1133h.) GYMNURA RAFFLESII, Vigors and Horsfield.

SYN.—*Viverra gymnura*, *Raffles*.

“Tikus ambang bulan,” *Raffles*.

HAB.—*Malacca*.

*Sumatra*, *Singapore*.

In a district not distant from *Malacca*, the animal is said to be numerous, though not to be seen in other localities.

GEN.—SOREX, *Linne*.

(1133i.) SOREX MURINUS, *Linne*.\*

\* The following Syn. are given in *Gray's List of Mam. in British Museum* : *Sorex myosurus*, *Pallas*. *Geoff. Ann. Mus. XVII. S. Sonneratii*, and *S. giganteus*, *J. Geoff. Mem. XV, S. indicus*, *Geoff. Mem. Mus. I. S. capensis*. *Geoff. Ann. Mus. XVII. S. Pilorides*, *Shaw. Mus. Liver. S. cærulescens*, *Shaw, Zool. S. crassicaudatus*, *Licht. Saugeth. SYN.—*Sorex myosurus*, *Pallas*, apud *Schinz*.

*Sorex cærulescens*, var, *Raffles*?

“Chinchorot” of the Malays of the Peninsula.

HAB.—*Pinang*. *Java*.

Dark brownish-grey above ; beneath light brownish-grey. Feet and tail flesh-coloured in the living animal, changing to cinereous after death. In the young the colour is more of a bluish-grey, slightly mixed with the brown on the back. Length of the head and body five and half inches ; tail three inches.

2	0	8.8
Incis. —	Canin. —	Molar, —
9	0	5.5

The present differs from the ‘Musk Shrew’ of Bengal (“Choochundr”) in its proportionally broader, more developed, and from the head more diverging ear, which characters also distinguish it from *Sorex nigrescens*, *Gray*, which it somewhat resembles in its colours. The smell of musk, emitted by the adult animal, and which in the young is barely perceptible, is much less intense than that of the Bengal Musk Shrew.

## CARNIVORA.

GEN.—URSUS, *Linne*.

HELARCTOS, *Horsfield*.

(1133j.) HELARCTOS MALAYANUS, *Horsfield*.

SYN.—*Ursus Malayanus*, *Raffles* and *Horsfield*.

“Bruang” of the Malays.

HAB.—*Malayan Peninsula*. *Sumatra*, *Tenasserim* Provinces, *Assam*, *Nipal*.

Colour of the young : snout and lips pale ferrugineous. Head, back, and outside of the limbs black, mixed with pale rust colour, in consequence of many of the black hairs having the point, or a part next to the point, of the latter colour. Ears, tail, paws, and inner side of the extremities shining black. The somewhat woolly hairs of the abdomen are faintly marked with ferrugineous, and are mixed with longer stiff black hairs. As observed by *Schinz*, the mark on the breast is very variable in its form. It may be compared to a crescent, assuming according to the smaller or greater breadth of the limbs, the shape of the letter U, of a horse shoe, or a heart. In the living animal it is of a pale rust, or orange colour, in some individuals with a few small blackish spots, fading after death to a yellowish-white. A very old male presented the following dentition :

6	1—1	4.4	(2 + 2)
Incis. —	Canin. —	Molar, —	
6	1—1	6.6	(3 + 3)

In a young female, three feet in length, the intestinal canal measured fifteen feet. It had neither cæcum nor valve to mark the transition. She had ten grinders in either jaw, of which four were spurious, six true.

GEN.—ARCTICTIS, *Temminck*.

(1133k.) ARCTICTIS BINTURONG, *Fisher*.

SYN.—*Viverra*? *Binturong*, *Raffles*.

*Paradoxurus albifrons*, *F. Cuvier*.

*Ictides ater*, *F. Cuvier*.

*Arctictis penicillata*, *Temminck*.

*Ictides ater*, *Blainv. Calcutta Journ. of Nat. Hist.\**

“Unturong” of the Malays of the Peninsula.

\* In the 3rd Vol. of *Calcutta Journ. of Nat. Hist.* p. 410, occurs the following passage : “The Binturong was first discovered in Java, but the first notice of its existence on the continent of India will be found in the second volume of this Journal, p. 457,” (sic!) “&c.” *Sir Stamford Raffles*, who published the first account of this animal, distinctly states, that it was discovered at *Malacca*, (not *Java*, as erroneously stated,) by *Major Farquhar*, and *Malacca* is situated on the continent of India as well as *Tenasserim*. The fact of its inhabiting *Bhotan*, was according to *Cuvier* (*Regne Animal*), first made known by *Duvaucel*, and the author of the article “*Ictides*” in the *Penny Cyclopædia*, 1838, gives *Mr. Hodgson*’s authority of the *Binturong*’s inhabiting

Nipal, (Kachar, though they occasionally occur in the central region of Nipal.)

“Unturong” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Tenasserim, Arracan, Assam, Bhotan, Nipal.

Java and Sumatra are quoted by M. Schinz, but neither Dr. Horsfield, Sir S. Raffles, nor M. Temminck, (*Discours Preliminaire, Fauna Japonica*), mention the *Binturong* as inhabiting either of the two islands.

The general colour of either sex is black, sprinkled on the body and extremities with pale ferrugineous, produced by some of the hairs having a part next to the point of that colour. In both sexes nearly all the hairs of the head, face and throat are thus marked, which communicates to these parts a whitish or greyish appearance. In the young of either sex there is a faint trace of a white spot over the eyes. The long ear tufts are always black, the margin of the auricle being either white, or pale rust-coloured. The tail is black, but the hairs of the anterior or basal half, are whitish at the root, or in some uniformly of that colour. The pupil is vertically contracted by the influence of light; the iris is of a beautiful Van Dyke brown. In its habits the *Binturong* is both arboreal and terrestrial, and nocturnal, sleeping till the sun is below the horizon, when it displays great agility in searching for smaller quadrupeds, birds, fishes, earth-worms, insects and fruit. The howl is loud, resembling that of some of the *Malayan Paradoxuri*. The young are easily tamed, but the old animal retains its natural fierceness. Between the anus and penis is situated a large pyriform gland, exceeding two inches in length, partially divided by a deep naked fossa, commencing from the latter organ. The gland secretes a light-brown oily fluid, of a peculiar intense, but not fetid or sickening odour. In a young male, measuring from the nose to the root of the tail, two feet three and five-eighth inches, the tail two feet two and a half inches, the intestines were of the following dimensions:

Small Intestines,..... 7 feet 11 inches.

Large do..... 1 foot 10 inches.

Cæcum,..... 0  $\frac{1}{2}$  inch.

The circumference of the small intestines about seven eighth inches; of the large but little more, but the rectum was thickened two inches in circumference.

The short cæcum is crescent-shaped, or lengthened pyriform. The stomach is remarkably lengthened cylindrical, the parietes much thickened towards pylorus. Oesophagus enters close to fundus ventriculi, in consequence of which there is but a slight difference between the curvatures.

Length along the greater curvature, 1 foot 2 ins.  
“ smaller „ 1 „ 1 „

The circumference from cardia round fundus ventriculi measured five and a half inches; round pylorus two six-eighth inches. Both the gall-

bladder and the spleen presented a remarkably elongated shape. The former organ, lengthened pyriform, measured in length two inches; ductus cysticus two and a half inches. The spleen, tapering to a narrow point, was half an inch broad, and eight and a half inches in length. Costæ veræ, nine pairs; spuræ, five pairs = fourteen pairs.

GEN.—*MUSTELA*, Linnæ.

*PUTORIUS*, Cuvier.

(1133l.) *PUTORIUS NUDIPES*, Fred. Cuvier.

SYN.—*Mustela nudipes*, Desmar. apud Schinz.

“Pulasan” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Sumatra, Borneo.

The muzzle and the soles of the feet are pale flesh-coloured. The animal is said to inhabit the densest jungle, and is most difficult to obtain.

*MUSTELA*, Cuvier.

*MUSTELA FLAVIGULA*, Boddaert.

SYN.—*Viverra quadricolor*, Shaw.

SYN.—“Barang Barang” or “Ambrang,” Raffles.

*Lutra leptonyx*, Wagner, apud Schinz.

*Lutra Simung*, Schinz?\*

“Mumrang” or “Amrang” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Sumatra, Borneo.

\* In Schinz’s diagnosis of *Lutra Simung* is said “ungvibus robustis falcularibus,” (“die Nagel an den zehen sind stark und gekrümmt”) which if the passage refers to *Lutra leptonyx*, Horsfield, must be a mistake, as the original diagnosis expressly states “ungvibus brevibus sublamnaribus.” As Schinz describes *Lutra Barang* “ungvibus minutissimis obtusis” *Lutra*

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

*leptonyx* is probably meant, and thus the one species is mistaken for the other.

The young are very playful, and soon become sufficiently domesticated to roam about the house, and to appear when called. Its voice is a short shrill whistling, not unlike the sound of the cricket, but stronger. Its food is not confined to fishes and crustacea; birds and insects are equally relished. The muzzle is hairy, but in the old animal the hairs become rubbed off. The Malayan individuals appear to attain to a greater size than the Sumatran, described by Raffles. An old male measured from the apex of the nose to the root of the tail two feet eight and a half inches; the tail one foot eight inches. In a young male two feet and two inches, and the tail one foot two-eighth of an inch in length, the simple intestinal canal measured nine feet and one inch, with a circumference throughout of about two and two-eighth inches. No cæcum. Each of the kidneys consisted of ten loosely connected glands.

"Anjing Ayer" of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Java, Sumatra, Singapore, Nipal.

This, as well as the two preceding species, inhabits numerous the banks of the Malayan rivers, and all are at times used by the Malays in river fishing.

GEN.—CANIS, Linne.

CUON, Hodgson.

(1133p.) CUON PRIMÆVUS, Hodgson.

SYN.—*Canis primævus*, Hodgson.\*

\* Mr. Ogilby considers *Canis Dukhunensis*, Sykes, and *Canis primævus*, Hodgson, to be identical, and apparently not different from *C. Sumatrensis*, Hardwicke, (*Mem. on the Mammalogy of the Himalayahs*, apud Royle.) Colonel Sykes, on the contrary, describes *C. Dukhunensis* as being "essentially distinct from *Canis Quao*, or *Sumatrensis*, Hardwicke."

*Chrysæus primævus*, Hamilton Smith.

*Chrysæus socatus*, Cantor.

"Anjingutan" of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Bengal Nipal.

Some slight differences occur in the Malayan individuals. The inferior surface, the inside of the ears and limbs, the lip and throat, are of the same colour as the back, but much paler. A black carpal spot, like that of the wolf, is very distinct in the male, less so in the female. The young animal of either sex has a faint white spot with a

few blackish bristles, situated nearly midway between the angle of the mouth and the ears. Of the wavy wool of the Buansu, the Malayan wild dog, inhabiting a tropical climate, has but a little on the inner side of, and immediately behind the ear; the posterior part of the abdomen is almost naked. The short bristles of the lips, cheeks, throat, and above the eyes, are all black. In habits, so fully described by Mr. Hodgson, and in size, the Malayan agrees with the Nipalese. In a young male, from the nose to the root of the tail two feet height and a half inches in length; the tail one foot, the intestinal canal was of the following dimensions:

Small Intestines,..... 6 feet 2 inches.

Large, ditto,... .. 0 ,, 10½ ,,

Cæcum,... .. 0 ,, 4 ,,

The latter intestine is spiral, much widened at the origin.

Costæ veræ 8 pairs, spuriae 5 pairs=13 pairs.

The Malays mention another, black wild dog ("Anjing utan etam,") as also inhabiting the densest jungle. A Hyena is also reported to occur on the Peninsula.

Mongrel curs, "pariah dogs," of every description, infest every village, but apparently not uninhabited places, nor localities far distant from the dwellings of man. As they all may be said to be in a state of half domestication, and are of forms very different from the wild dog, which shuns the human presence, their origin cannot with certainty be traced to the Malayan Peninsula.

GEN.—VIVERRA, Linne.

(1133q.) VIVERRA ZIBETHA, Linne.

SYN.—*Viverra undulata*, Gray.

*Viverra melanurus*, Hodgson.

*Viverra orientalis*, Hodgson.

*Viverra civetoides*, Hodgson.

Undescribed Civet, McClelland.

} Apud  
Gray:  
List.

"Tangallong" of the Malays of the Peninsula.

HAB.—*Pinang, Singapore, Malayan Peninsula*. Southern China, Siam, Bengal, Khasyah Hills, Nipal.

Judging by the comparatively few individuals observed in the Straits of Malacca, this species would appear to be far less numerous, than the following. Of several, the largest, which was a female, measured from the apex of the nose to the root of the tail two feet and eight inches; the tail one foot height and a half inches.

(1133r.) VIVERRA TANGALUNGA, Gray.

SYN.—*Viverra Zibetha*, Lin. apud Raffles.

"Tangalung," Raffles.

*Viverra Zibetha*, Lin. apud Horsfield.

*Viverra Zibetha*, apud Fred. Cuvier.

*Viverra Zibetha*, Lin. apud Schinz.\*

"Musang jebat" of the Malays of the Peninsula.

\* The true *Viverra Zibetha*, Linne, is quoted by Schinz under the denominations of *V. ben-*

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

*galensis*, Hardwicke (?), and *V. melanura*, Hodgson.

HAB.—*Pinang, Singapore, Malayan Peninsula, Sumatra, Borneo, Celebes, Amboyna, Philippines.*

This species is readily distinguished from *V. Zibetha* by a continuous longitudinal black band occupying the upper surface of the tail, the numerous irregular rings being separated only on its inferior half. (Gray: Proceed. Zool. Society, 1832, p. 63.) The number and distance of the half rings on the lower surface of the tail, vary in different individuals, some of which have either the entire tail, or the anterior half or third of the tail, thus marked, the rest being black. The very young animal is generally of a much darker ground colour than the adult, and the black marks are therefore less conspicuous. Under certain lights the colour appears uniformly black. *Viverra Tungalunga* and *Zibetha*, however similar in habits and general colours, neither live nor breed together. Placed side by side, the living animals present a marked dissimilarity of countenance, which although obvious to the eye, would be most difficult, if possible at all, to convey in words. The female has three pairs of mammae, and produces from one to three young. The Malays of the Peninsula distinguish by different names the *Zibetha* and the *Tungalunga*, but as they suppose the civet of the former species to be of better quality, perhaps because it is scarcer, they will frequently offer for sale individuals of the latter, exceedingly numerous species, imposing upon it the name of *V. Zibetha*: "Tanggalong" of the Peninsula. The largest individual of the present species observed, measured in length from the apex of the nose to the root of the tail three feet and one inch; the tail one foot five and a half inches. In a young, a female, three feet five and a half inches in length, of which the tail one foot and one inch, the intestinal canal was of the following dimensions:

Small Intestines,..... 7 feet 5 inches.  
Large ditto,..... 0 „ 9 „  
Cæcum, ... .. 0 „ 1 „  
Costæ veræ, seven pairs; spuræ, six pairs  
=thirteen pairs.

VIVERRICULA, Hodgson.

(1133s.) VIVERRICULA MALACCENSIS.

SYN.—*Viverra malaccensis*, Gmelin.

*Viverra Rasse*, Horsfield.

*Viverra Gunda*, Buchanan Hamilton MSS.

*Viverra indica*, Geoffroy

*Viverra bengalensis*, Gray: Illustr.

*Viverra pallida*, Gray: Illustr.

*Genetta Manillensis*, Eydoux.

HAB.—*Malayan Peninsula. China, Philippine Islands, Java, Singapore, Cochin China, Tenasserim Provinces, Bengal, Nipal, Hindoo-stan, Dukhun, Bombay.*

On the Malayan Peninsula this species appears to be more numerous than *V. Zibetha*; less so

The largest observed was three feet four inches in length, of which the tail one foot three and a half inches. In a male, measuring from the apex of the nose to the root of the tail, two feet and three-fourth of an inch, the tail one foot one inch, the dimensions of the intestinal canal were:

Small Intestines,.. .. 4 feet 0 inch.

Large ditto,..... 0 „ 8 „

Cæcum,..... 0 „ 0½ „

The three preceding species have the following characters in common. The pupil is vertical, oblong; the iris of a rich brown. They are arboreal as well as terrestrial, preying upon the smaller quadrupeds, birds, fish, crustacea, insects and fruit. Naturally very fierce, they are scarcely reclaimable except in youth, but with age the original disposition returns. Their voice is peculiar, hoarse and hissing.

GEN.—PRIONODON, Horsfield.

(1133t.) PRIONODON GRACILIS, Horsfield.

SYN.—*Viverra?* Linsang, Hardwicke.

*Felis gracilis*, Horsfield.

*Viverra* Hardwicke, Lesson.

*Viverra gracilis*, Desmarest, apud Schinz.

*Linsang gracilis*, Muller, apud Gray.  
List, and Schinz.

HAB.—*Malayan Peninsula. Java, Sumatra, Borneo, Siam.*

The ground colour is buff, and the dark marks are of a deep snuff colour, inclining to black with purple reflection. Length from the apex of the nose to the root of the tail: one foot six inches, the tail one foot three six-eighth inches.

Mr. Rappa, for many years a dealer in objects of natural history at Malacca, who previously had been supplied with a figure and description of *Prionodon gracilis*, reported in a memorandum accompanying the specimen, that it had been captured in the jungle at some distance from Malacca. It was unknown to himself and to the natives. At first the animal was fierce and impatient of confinement, but by degrees it became very gentle and playful, and when subsequently suffered to leave the cage, it went in search of sparrows and other small birds, displaying great dexterity and unerring aim in stealthily leaping upon them. Fruit of every description it refused. Another younger individual was captured about the same time, but contrived to make its escape.

GEN.—PARADOXURUS, Fred. Cuvier.

PAGUMA, Gray.

(1133u.) PAGUMA LEUCOMYSTAX, Gray: List?

"Musang bulan" of the Malays of the Peninsula.

HAB.—*Malayan Peninsula. Singapore, Sumatra.*

In a single individual observed, the hairs of the body, limbs and anterior third of the tail, are greyish-yellow at the base, next bright rust co-

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

duces a mixture of ferruginous and black, the latter prevailing on the nape of the neck, middle line of the back, and the anterior third of the tail. The hairs of the vertex and the ridge of the nose are dark at the base, with yellowish points. The large oblique whitish spot in front of the ear, produced by uniformly whitish hairs, is on either side blended with the whitish vertex and ridge of the nose, and is continued down the sides of the neck, forming a large broad arrow-shaped mark. The orbits are dark brown, the face, lips and throat pale brown. The long rigid white whiskers are mixed with a few shorter black bristles. The feet are dark brown, the posterior two-thirds of the tail uniformly black. The lower surface and the inner side of the extremities are pale ferruginous. From the apex of the nose to the root of the tail: two feet three inches, the tail one foot eight inches.

(1133v.) *PAGUMA TRIVIRGATA*, Gray: List.  
 SYN.—*Viverra trivirgata*, Reinwart, Mus. Leyd.  
*Paradoxurus trivirgatus*, Gray.

“Musang akar” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Singapore, Tenasserim.

The ground colour varies from yellowish, or brownish, to blackish-grey. Fur short, peculiarly soft, silky. The dorsal streaks are either continued, undulated, (the central nearly always,) are composed of separate black spots. Some individuals have a short white streak on the ridge of the nose. The largest male measured from the apex of the nose to the root of the tail, two feet two and a half inches; the tail two feet three inches.

(1133w.) *PARDOXURUS MUSANGA*, Gray.

“Musang” or “Musang Pandan,”  
 (when the tail is with white point:  
 “Musang Bungkwang,”) of the Malays  
 of the Peninsula.

HAB.—*Pinang, Singapore, Malayan Peninsula*.  
 Java, Sumatra, Borneo, Timor.

The ground colour and dorsal marks of this exceedingly numerous species are liable to considerable variations, the principal of which are

noted by Schinz: individuals occur (probably of every species) with the apex of the tail white, with elongated white spots on the abdomen, with the tail spirally twisted. In most the dorsal marks become indistinct, or invisible in certain lights. The female has from one to three young, of colours similar to the adult, but less distinct, their fur is softer, somewhat woolly, mixed with longer stiff black hairs. The young is tamed without difficulty, and is sometimes kept in houses to destroy rats and mice. The *Paradoxuri* are in habits like the Civets. They have an elliptical pupil, vertically contradicted by the influence of light. Their glandular secretion is of a peculiar, not civet or musk-like odour. The largest specimen of a great number, measured from the apex of the nose to the root of the tail two feet and half an inch; the tail one foot four and a half inches. In a male, measuring three feet one and a half inch in length, of which the tail one foot four and a half inches, the intestinal canal were of the following dimensions:—

Small Intestines,..... 5 feet 8 inches.

Large ditto, ..... 0 „ 5 „

*Hemigalea Zebra*, Jourdan.

*Viverra Boiei*, Muller.

“Musang Batu” or “Sangah Prao” of  
 the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Borneo.

The ground colour varies from pale ochreous to buff, and the dark marks in shape and number scarcely alike in any two individuals, from snuff colour to black. The species apparently not numerous, and is celebrated among the Malays for its great agility. It is said chiefly to feed upon the larger birds, such as the Argus pheasant, which it will hunt down, following its prey till the strength of the latter is exhausted, when it falls an easy victim to the indefatigable pursuer. The slender vermiform make the countenance and distribution of colours; the serrated, flattened false molars; the soles, hairy between and under the toes, and slightly in the centre; the somewhat removed thumb, are characters by which this animal differs from *Paradoxurus*, and form a link between that genus and *Prionodon* in the same manner that *Viverricula* connects *Viverra* to *Prionodon*. The largest male observed measured from the apex of the nose to the root of the tail two feet; the tail one foot and four inches.

GEN.—*CYNOGALE*, Gray.

(1133y.) *CYNOGALE BENETTII*, Gray.

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

**HAB.**—*Malayan Peninsula*. Sumatra, Borneo.

The very young, of which two individuals, a male and a female, were found with the mother, differ from the adult in having a very soft, silky, dense fur, mixed with longer hairs, which are black, except on the chest and abdomen, where the apex is silvery. Over the tarsus and on the upper surface of the feet some of the hairs have a subterminal white band, close to the black apex. The posterior margin of the ear is hairy and of a silvery colour. This animal appears to be of rare occurrence on the Malayan Peninsula, and the natives are consequently not acquainted with it. The largest male examined measured from the apex of the nose to the root of the tail two feet three inches; the tail eight inches.

**GEN.**—*HERPESTES*, Illiger.

<i>Leopardus Javanensis</i> ,	

“Rimau akar” of the Malays of the Peninsula.

HAB.—*Pinang, Malayan Peninsula. Java, Sumatra?*

The ground colour in the Malayan individuals varies from pure grey to greyish brown or ferruginous. The largest adult male measured from the apex of the nose to the root of the tail one foot eleven and a half inches, the tail ten inches; another of equal dimensions of the body had the tail eight inches in length. The intestinal canal was of the following dimensions:

Small Intestines, ... 3 feet 8 inches.

Large, ... 0 „ 9½ „

Cæcum, ... 0 „ 1½ „

In the scansorial habits of this very numerous species originates its local denomination “akar,” signifying a climber as well as a root.

(1133hh.) *FELIS PLANICEPS*, Vigors and Horsfield.

SYN.—*Chaus* (?) *planiceps*, Gray: List:

“Kuching-utan,” or “Jalang” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula. Sumatra, Borneo.*

The Malayan individuals of this apparently not numerous species differ from the Sumatran,

originally described, in having the whitish throat, chest and abdomen, and the inner side of the limbs undulated with brown, transversal, interrupted bands. In none of the Malayan wild cats is the length of the tail more variable. In a male, measuring from the apex of the nose to the root of the tail two feet one and a half inch, the tail, consisting of twelve gradually diminishing caudal vertebræ, measured five and a half inches; in another, one foot ten and three-fourth inch in length from the nose to the root of the tail, the latter organ measured two inches, consisting of four slightly decreasing vertebræ, the last one of which was broad, flattened, and rounded at the posterior extremity. It is of most ferocious habits, and untameable. In the smaller individual the intestinal canal was of the following dimensions:

Small Intestines, ... 3 feet 6½ inches.

Large, ... 0 „ 5½ „

Cæcum, ... 0 „ 0½ „

*FELIS DOMESTICA*, Auct.

“Kuching” of the Malays.

The Malays, like most Muhamedans, are as partial to cats as they are the reverse to dogs. As observed by Sir S. Raffles, some of the Malayan, like the Madagascar domesticated cats, have a short twisted or knobbed tail, others are tailless. Among those of an uniform colour, a light ashy and a bluish (or slaty grey) variety, with single longer black hairs on the back and tail, are conspicuous. They frequently relapse from a state of domestication, resort to the jungle, and shun the presence of man.

“Chingkrawa etam” of the Malays of the Peninsula.

\* *Sciurus Javensis*, Schreber, and *bicolor*, Sparrmann apud Gray: List, is *Sciurus Leschenaultii*, Desmar, apud Horsfield. Syn. *S. hypoleucus*, Horsfield.

HAB.—*Penang, Malayan Peninsula. Java, Sumatra, Borneo, Siam, Tenasserim, Assam, Nipal.*

The original diagnosis will prevent misunderstanding as to the species under consideration. “*Sciurus supra niger, infra fulvus, auriculis acutis imberbibus, palmarum angue pollicari magno rotundato.*” (Sparrmann, apud Horsfield.) The colour of the head, back, tail, outside of the extremities, and the feet, is intense shining

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

black, the single hairs being blackish-grey at the root, those of the tail blackish-brown at the root. In some individuals the black hairs generally, in others those of the tail, or some part of the back only, have a broad subterminal band of bright cinnamon, or Indian red, which imparts a red-dish tint to the general black colour. The mustachios, whiskers and the superciliary bristles are black; those of the throat and forearm are black in some, ferruginous, or with the apex of that colour, in others. The under-parts vary from a deep golden fulvous to isabella colour. Whatever be the prevailing shade, it is always most distinct on the lateral line, which, commencing from the cheeks, passes along the sides of the body. The fur of the lower parts of the body, and of the inside of the extremities, is much shorter, softer, and less dense, than that of the back. The single hairs are greyish, or blackish at the root, with the apex of the shade of yellow prevailing in the individual. Single long bristles, either uniformly, or partially black, or fulvous, appear on the chest and abdomen. The species, under the present garb, is very numerous in the Malayan forests and hills.

## VAR. B. Horsfield.

"*Sciurus supra fuscus, varians a fusco-nigricante ad sordide fulvum, pilis velleris fulvis et canescentibus intermixtis, subtus fulvus vel pallide flavescens.*"—Horsfield.

SYN.—*Sciurus auriventer*, Is. Geoff. apud Schinz.  
*Sciurus aureiventer*, Is. Geoff. apud Gray : List.

"Chingkrawah" or "Chingkrawah puteh" of the Malays of the Peninsula.

Single individuals, resembling the Javanese one figured in '*Zoological Researches in Java*,' occur at Penang, but there, as in Java, tawny of different shades, with a greyish cast, is more frequent. In some the head is of a darker colour, in others large spots of dark appear on the back, or the tail is above barred with dark. The upper part of the nose, a ring encircling the eyes, and the ears appear in all individuals to be of a darker brownish colour, and all have a more or less distinct large white spot on the anterior and upper part of the thigh. The back of the feet is either dark brown or fulvous. The palms, soles, mammae and genital organs, are black in all.

The single hairs of the back are greyish-brown at the root, darker than the apex, which imparts the general colour to the back. With the hairs of the tail the reverse is the case, the basal half being isabella or white; the apical darker. On the lower surface of the distichous tail, the roots of the hairs form a white line on either side of the vertebræ, which are covered with short, dark-brownish, or fulvous hairs. The under-parts of the body are of the same colours as those of the black-coated animal, but their roots are yellowish-white. The mustachios, whiskers, and other bristles, are in all of a black-

ish-brown; but the single bristles of the abdomen are sometimes fulvous.

The black-coated individuals stand in a similar relation to the light coloured varieties, as that in which the black-coloured *Hylobates Lar* stands to the light-coloured. Such differences of colour, wide no doubt, are of no uncommon occurrence among the Malayan Mammalia, and ought to be well considered by Zoologists, who have not the opportunity of studying the living animals.

This, as well as the rest of the Malayan squirrels, is capable of being tamed to a certain extent, and evinces attachment to those who feed them, but the appearance of a strange person, animal, or even an unusual sound, startles them, and recalls their natural shyness. The largest of a great number, measured from the apex of the nose to the root of the tail one foot six inches, the tail one foot nine and a half inches. The intestinal canal was of the following dimensions :

Small Intestines,.....	9 feet 6 inches.
Large do. ....	4 „ 9 „
Cæcum,.....	1 „ 2 „

(1133jj.) *SCIURUS RAFFLESII*, Vigors and Horsfield.

SYN.—*Sciurus rufogularis*, Gray.

*Sciurus rufoniger*, Gray.

*Sciurus Prevostii*, Desmar, apud Schinz.

"Tûpai balang" of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Java, Borneo, China\* (Canton.)

\* China is the habitat assigned to *Sciurus rufogularis*, Gray. Without doubting the authenticity, it is perhaps as well to observe, that skins of the more showy animals and birds of India, Malacca, and the Indian Archipelago, are offered for sale as indigenous productions in the shops of Canton and Macao. Skins of *Halcyon Smyr-nensis* for instance, and other birds from different parts of India, are bought up by the Chinese merchants of our colonies in the Straits of Malacca, who annually, on Chinese Junks, ship quantities of considerable value to China, where they are manufactured into fans and artificial flowers. In a list of birds, contained in a collection of Chinese productions, exhibited in London in 1842, Mr. H. E. Strickland observes in his communication to the Zoological Society, that some of them appear to have been imported from Malacca. Skins and other parts of a host of animals, from the most distant parts of Asia, form items in the Chinese Pharmacopœia. On my visits to Chinese Dispensaries in China and in our Malayan Colonies, I have been shewn horns of rhinoceroses and deer, tusks of the Duyong, heads of Bucer, tortoise-shells, and well preserved skins of *Trigonocephalus Blomhoffii*, from Japan; Ammonites and other fossils, *cum multis aliis*, all supposed to possess specific

virtues, and accordingly prescribed by Chinese Medical practitioners.

This species, numerous in the Malayan countries, occurs with the following individual variations of colour—

Cheeks and throat iron-grey, shoulders uniformly, or mixed with red. (*Sciurus rufogularis*, Gray, *Mag. Nat. Hist.* 1842, p. 263.)

The cheeks are sometimes dark-brown, or ferruginous.

In some, the white lateral line commences from the side of the nose, passing over the cheeks, the side of the neck, and over the shoulder. The lateral line is either pure white, more or less distinct, or mixed with single longer hairs with black apex.

Some have a short black line immediately below the white; in others there is above the latter a grizzled line, sometimes continued over the outside of the thigh. The tail is seldom uniformly black, frequently partially black, reddish or grizzled, owing to the apex of the hairs being white. The tuft is frequently reddish or rust-coloured.

The feet are sometimes white or pale ferruginous.

The Museum of the Asiatic Society possesses a specimen from Java, differing from *Sciurus rufoniger*, Gray, in having the tail grizzled instead of black. *Sciurus redimitus*, Van der Boon, is probably another variety of *S. Rafflesii*.

A young male, about a fortnight in confinement, after having finished his usual meal of coconut, seized and devoured an *Iora typhia*, which had just been shot, and happened to be placed within reach. Sparrows and other smaller birds were subsequently eaten, and apparently relished.

The largest male measured from the apex of the nose to the root of the tail eleven and a half inches; the tail one foot two inches.

(1133kk.) *SCIURUS HIPPIURUS*, Is. Geoffroy.

SYN.—*Sciurus erythræus*, Pallas (?) } Apud  
*Sciurus caudatus*, McClelland ? } Gray:

*Sciurus rufogaster*, Gray.

*Sciurus castaneiventris*, Gray,  
 "Tupai Jinjang," "Ummu," or "Jau"  
 of the Malays of the Peninsula.

HAB.—*Malayan Peninsula*. Java, Sumatra, Assam, China, (Canton).

The ground colour of the Malayan individuals differs but slightly, according to the more red or yellow rust colour of the bands of the hairs. The anterior part of the tail above is of the same colour as the back, the rest is either uniformly black, reddish, or with transverse bands, or has the tuft of that colour. The colour of the ears is brownish in some, but generally of the leaden grey, grizzled colour of the head, cheeks, chin and outside of the limbs. The feet are black or slightly grizzled.

The largest individuals of this numerous species measure from the apex of the nose to the root of the tail one foot; the tail one foot and half inch.

HAB.—*Singapore, Penang, Malayan Peninsula*. Sumatra, Borneo, Canton.

This is the most numerous species in the Straits of Malacca, the largest individuals measuring from the apex of the nose to the root of the tail eleven inches; the tail eleven inches.

(1133mm.) *SCIURUS NIGROVITTATUS*, Horsfield.

SYN.—*Sciurus griseiventer*, Is. Geoffroy, apud Schinz.

HAB.—*Malayan Peninsula*. Java, Sumatra, Borneo, Canton.

Not numerous; the largest individual observed, a female, measured from the apex of the nose to the root of the tail nine inches; the tail eight and a half inches.

(1133nn.) *SCIURUS TENUIS*, Horsfield.

SYN.—*Sciurus modestus*, S. Muller?

HAB.—*Singapore, Malayan Peninsula*. Java, Sumatra, Borneo, Canton.

Of two individuals observed, the larger, a male measured from the apex of the nose to the root of the tail six inches; the tail seven inches.

(1133oo.) *SCIURUS LATICAUDATUS*, Diard, Var.

SYN.—*Sciurus laticaudatus*, Diard, apud S. Muller?\*

\* In the *List of Mammalia in the British Museum* occurs a genus: *Rhinosciurus*, Gray, and a species *R. tupaioides*, Gray, Syn. *Sciurus laticaudatus*, Müller?? Generic or specific characters being neither given nor referred to, it is impossible in India to decide whether the specimen in the British Museum thus labelled, is identical with the animal here characterised.

HAB.—*Malayan Peninsula*.

The present squirrel differs from the diagnosis of *Sciurus laticaudatus* from the west coast of Borneo, (communicated in *Natuur en Geneeskundig Archief*, &c., II, Jaarg. 1 Aflev. p. 87,) in having neither the first nor the fifth molar of the upper jaw very large. Both are of nearly equal size, and much smaller than the rest. The following is a description of the Malayan animal.

The shape of the head is depressed, elongated, conical, gradually attenuated towards the laterally compressed nose. The whole outline, the slender form, and general colours, render the animal strikingly similar to *Tupaia ferruginea*. The eyes are large, brilliant, dark; the ears large,

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

oval, with smooth short hairs; the mouth is small, the upper incisors are very minute, the lower slender, flattened, and almost straight; the black mustachios, whiskers, superciliary and angular bristles, and the few white ones of the forearm, are all shorter than the head; the muzzle hairy, leaving the margins of the small, and at the apex laterally pierced nostrils, naked. The limbs and feet slender; the nailless tubercle of the thumb rudimentary, barely perceptible in the living animal. The claws are small, sharp, compressed, whitish.

The colour of the head, back, outside of the limbs and feet, is a rich rusty-red, mixed with shining black, particularly on the occiput, the back and the feet, less on the sides, where the ferruginous prevails; the throat, chest, abdomen and inner side of the limbs, whitish; in some individuals pale-yellowish. The fur is soft and delicate. The separate hairs are leaden-grey at the base, shining black, or with a broad subterminal ferruginous band. The tail is shorter than the body, distichous, broadest in the middle, attenuated at the root, terminating in a thin tuft. It may be compared to a feather, black on each side of the quill, successively ferruginous, again black, margined with buff. Such is the succession of the bands on the separate hairs. This organ is less full and ornamental than in the generality of squirrels. The species is apparently not numerous; the largest out of five examined, a female, was of the following dimensions:—

Length from the apex of the nose to the root of the tail,.....	10 $\frac{5}{8}$ inch.
„ of the tail,.....	6 $\frac{3}{8}$ „
„ of the head,.....	2 $\frac{3}{8}$ „
„ from the apex of the nose to the anterior angle of the eye,...	1 $\frac{2}{8}$ „
„ from the posterior angle of the eye to the ear,.....	0 $\frac{5}{8}$ „
Breadth above the apex of the nose,...	0 $\frac{1}{8}$ „
„ between the anterior angles of the eyes,.....	0 $\frac{7}{8}$ „
„ between the ears,.....	0 $\frac{6}{8}$ „
Diameter of the head at vertex,.....	1 „

Its habits in confinement presented nothing remarkable.

GEN.—PTEROMYS, Cuvier.

SYN.—Sciurus petaurista, Lin, apud Cuvier?

Sciurus petaurista, Chin Krawa, Raffles?

Pteromys albiventer, Gray Illustr.

“Tupai Terbang” or “Kubin” of the Malays of the Peninsula.

HAB.—Singapore, Pinang, Malayan Peninsula, Java, Sumatra, Borneo.

The part of the head anterior to the ears, the cheeks, the chest, and the abdomen, are white in some individuals of either sex, one of which is figured in Hardwicke's *Illustrations of Indian Zoology*, under the denomination of *Pteromys albiventer*, Gray.

The black, or dark-brown eyelids, nose, chin, feet and tip of the tail, appear to be constant characters. The shade, and intensity of the red colour is liable to considerable variations. [In an individual from Malacca, the back was very dark Indian-red, with a few dashes of pure white. The identity of the species is, however, doubtful.] In the very young, there is a short black stripe behind the ears; and the posterior part of the back and anterior half of the tail are shining black, from each separate hair having the apex of that colour. Traces of these characters occur in some adult individuals. This species is very numerous in the Malayan countries. It is not strictly nocturnal, for it is frequently seen abroad during the day. It is particularly fond of the Durian, the fruit of *Durio Zibethinus*, Linne. The flying squirrel has this partiality, in common with various other animals, as monkeys, Pteropi and Paradoxuri; nay, the Malays assert, that they have to watch this, their favourite fruit, against tigers.

In a female, measuring from the extremity of the nose to the root of the tail, one foot six and half inches; the tail one foot nine inches: the intestinal canal was of the following dimensions:—

Small Intestines, ..... 7 feet 4 $\frac{1}{2}$  inches.

Large, ..... 5 „ 2 „

Cæcum, ..... 2 „ 4 „

"Tikus bulow" of the Malays of the Peninsula.

\* The description of this supposed species *Calcutta Journal of Nat. Hist.* Vol II p 456, Pl. XIV.) states, "There are four toes to each fore-foot, and five to each hind-foot." The draughtsman of Pl XIV, "*Rhizomys cinereus*," has, at all events, observed, that all the feet are five-toed, however incorrectly he has represented the animal. Another error occurs in the description, viz.: "Sir Stamford Raffles describes a species of Bamboo Rat found in Sumatra by Colonel Far-

quhar," &c., Sir S. Raffles' words are these "MUS SUMATRENSIS. A drawing and specimen of an animal, which appears related to the *Mus Pilorides*, was forwarded from Malacca" (not Sumatra, as erroneously asserted) "by Major Farquhar, to the Asiatic Society at the same time with the Binturong. I am informed by him that it is not uncommon at Malacca, and is perhaps to be found in most parts of the Malay Peninsula", &c. *Transact. Linn. Society*, Vol. XIII.

HAB.—*Malayan Peninsula*. China, Moulmein, Assam.

Although the animal was first described in Sir Stamford Raffles' catalogue of collections, made in Sumatra, the author distinctly states that it was forwarded from Malacca by Major Farquhar; nor does it appear to inhabit Sumatra, although the specific name would lead one to suppose that such is the case. The colour of the adult is liable to individual variations, from grey of different shades to isabella or silvery-buff. The separate hairs are mostly of the colour prevailing in the individual, mixed with single dark-brown hairs with whitish apex, particularly on the vertex, continuing along the centre part of the back. On the nose, anterior part of the head, and on the cheeks, the hairs are of a pale rust colour. On the vertex some white hairs form either a spot or a short line of that colour. The scanty hairs of the abdomen are all of a pale-greyish or isabella colour. The mustachios, whiskers, superciliar and gular bristles, are either of a pale-brown or buff colour. The young are above of a dark-grey, with a brown streak on the vertex and back; beneath pale-grey. The forehead, nose, temples, and cheeks, are ferruginous. The adult, like some squirrels and rats, is subject to enlargement of the scrotum. In confinement, it is very savage, scarcely tameable. The length of the tail varies from about one-third to little more than one-fourth of the length of the body. It is blackish, or brownish; the apex whitish. The largest male examined, measured from the apex of the nose to the root of the tail, one foot seven and a half inches; the tail five and a half inches. The female, in size and colours equalling the male, has ten mammæ, viz. two axillary, and three inguinal pairs.

GEN.—*HYSTRIX*, Cuvier.

(1133yy.) *HYSTRIX LONGICAUDA*, Marsden.

SYN.—*Acanthion Javanicum*, Fred Cuvier?

*Hystrix brevispinosus*, Schinz.\*

"Babi Landak" of the Malays of the Peninsula.

\* In "*Nachtrage Zum 2ten, Bande*," this species is supposed to be identical with, and substituted for *Atherura fasciculata*, although a very correct description is given of both.

HAB.—*Malayan Peninsula*. Java, Sumatra, Borneo.

Sir Stamford Raffles has pointed out the inaccuracy of Marsden's figure, representing the forefeet with five toes, instead of with four, and a rudimentary thumb with a flat nail. The figure also has a few mane-like long bristles on the head, whereas the mustachios are situated on the side of the nose, the whiskers below the ear, and one or two bristles above the eye. In colours, this species resembles *Hystrix leucurus*, Sykes, from which it differs in the absence of the long mane-like bristles of the head and neck. Although single, scattered, thin, flexible spines, upwards of twelve inches in length, occur on the posterior part of the back, the majority of inflexible spines are much shorter than in *Hystrix leucurus* or *H. cristatus*, and are either pure white, or with a blackish band in the medial portion. The short, blackish, slightly iridescent spines of the neck, anterior part of the back, the limbs, and abdomen, are generally grooved on the upper surface. The short white pedunculated tubes of the posterior part of the tail are at first closed, terminating in a short spine, which latter wears off, leaving the tubes open. The pubes are disposed in a wreath of stiff bristles, frequently of a deep rust colour. The epidermis of this species, as well as of *Atherura* is remarkably thin and liable to be torn. Beneath the skin appears a fatty tissue, upwards of an inch in thickness. The anterior molars are slightly larger than the rest. Viewed from above, *in situ*, the crown of the anterior lower molar of either side presents the form of two letters S., facing each other (SS). In a foetus,—of which the head measures two and one-eighth inches, the body four and three-eighth inches, the tail one inch in length,—the whole of the body, and the anterior half of the tail have numerous short hairs, disposed on separate transverse lines of six to eight distant black hairs, becoming longer on the posterior part of the back and sides. The posterior part of the tail has longer and closer hairs. In a female, measuring from the apex of the nose to the root of the tail two feet five inches, the tail four inches, the intestinal canal was of the following dimensions :

Small Intestines,.....	21 feet	6 inches.
Large do.....	5 „	10 „
Cæcum,.....	1 „	7 „

The stomach is of a heart-shaped outline, with thin membranes externally smooth, internally with a few longitudinal rugæ near the narrow fundus.

The species is numerous, and, as it is considered a delicacy by the Chinese population, is frequently brought to market.

GEN.—*ATHERURA*, Cuvier.

(1133zz.) *ATHERURA FASCICULATA*, Cuvier,  
SYN.—*Hystrix fasciculata*, Lin., apud Cuvier.\*

\* No species of that name occurs in *Systema Naturæ*, Ed. XIII Gmelin, 1788, but *Hystrix macroura* is described “cauda longitudine corporis” (22) “anice fasciculo pilorum” &c.

*Hystrix orientalis*, Brisson, apud Gmelin.  
*Hystrix macroura*, Linne  
Porc-épic de Malacca, Buffon.  
*Hystrix fasciculata*, Shaw, apud Raffles.  
*Mus fasciculatus*, Desmarest.  
*Hystrix fasciculata*, Linne, apud Gray :  
Illustr.†

† In the figure, the anterior foot has one toe too many, the animal having four toes and a rudimentary flat-nailed thumb. Nor is the back of the hind foot naked, unless indeed become so by accident.

*Acanthion Javanicum*, F. Cuv.  
*Atherurus fasciculatus*, Schinz.  
*Atherurus macrourus*, Schinz.  
“Landak” of the Malays of the Peninsula.

HAB.—*Pinang, Malayan Peninsula, Java, Sumatra, Borneo.*

The nose, lips, forehead, and back of the feet, are covered with greyish-brown hairs. The body and limbs at the root of the spine, are covered with dense soft silky hairs, grey on the upper parts, and silvery on the abdomen. Single longer flexible spines, white with a dark central band, are scattered over the back. The anterior part of the tail is like the back, covered with flat-grooved spines, white at the root, then slightly iridescent brown, and frequently with white apex. The centre part of the tail is scaly, with very short spines between the scales. The posterior part is white; with white or silvery, flexible, and in length gradually increasing, spines, which Buffon has aptly compared to narrow slips of irregularly cut parchment. The pubes are of a deep rust colour.

This species is very numerous in the Malayan valleys and hills. In fretful habits, and in its food, it resembles the preceding porcupine, like which, it is carried to the market at Pinang and Malacca, where as many as twenty to thirty may frequently be seen. In a male, measuring from the apex of the nose to the root of the tail one foot ten inches, the tail ten inches; the intestinal canal was of the following dimensions :

Small Intestines.....	19 feet	4½ inches.
Large.....	5 „	3 „
Cæcum.....	1 „	3 „

The stomach is of a general outline, resembling that of *H. longicauda*, but it differs in having an external deep vertical sulcus, dividing the stomach into a pyloric and a cardiac portion, which latter presents 6 to 7 deep oblique sulci. The membranes of the stomach are thick and muscular. Internally the cardiac portion is transversally divided by six or seven ridges, corresponding to the external sulci, intersected by numerous concentric rugæ.

The pyloric portion, separated from the cardiac by the rugæ produced by the external vertical sulcus, is much smoother, and has but a few

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

## EDENTATA.

GEN.—MANIS, *Linne.*

(1133aa.) MANIS JAVANICA, Desmarest.

SYN.—*Manis pentadactyla*, Lin, apud Raffles.

*Manis aspera*, Sundeval.

*M. quipedactyla*, Raffles, apud Gray :  
List.

“Penjoling” or “Tangiling” of the Malays  
of the Peninsula.

HAB.—*Penang Malayan Peninsula*. Java,  
Sumatra, Borneo.

The series of dorsal scales vary in individuals  
from 16 to 19. The number of central dorsal  
vary from 20 to 22; the central and the marginal  
caudal from 25 to 29: in the young all the  
scales are finely lined and the rounded apex  
only is smooth. With age the lines become ob-  
literated on the exposed surface of the scales,  
between which appear a few long whitish bristles.  
The very young animal corresponds to the de-  
scription of *Manis aspera*, Sundeval. The eyelids,  
the margins of the ears, and the scaleless parts,  
except the palms and soles, are scantily provided  
with short whitish hairs. The two pectoral  
mammaræ are situated at a short distance from the  
axilla. Its habits present nothing different from  
those of *Manis crassicaudata* (*M. pentadactyla*,  
Linne), of which an interesting account is com-  
municated by Lieut. R. S. Tickell in *Journal*  
*Asiatic Society*, Vol. XI. 1842. p 231.

The present species, although numerous in  
rocky situations, is not often captured, as it is  
seldom abroad till after sunset. The largest male  
measured from the apex of the nose to the root  
of the tail one foot nine and a half inches; the  
tail one foot eight inches. In a younger male,  
the entire length of which was one foot eleven  
inches; the intestinal canal was of the following  
dimensions:

Small Intestines..... 8 feet. 4 Inches.

Large ditto,..... 0 „ 6 „

Cæcum is rudimentary, indicated by a slight,  
yet distinct widening of the intestines. The sto-  
mach is capacious, the pyloric region thickened  
and gizzard like. On the external surface, where  
the greater curvature begins to ascend, is situated  
a small (one inch in length, one and three-eighth  
in breadth) triangular, externally gyrated, glan-  
dular body, firmly attached to the stomach, but  
not communicating with the cavity. Its external  
appearance might be compared to that of a crest  
of ostrich feathers. The narrowed apex, towards  
the pylorus, is provided with a small, thick,  
rounded and wrinkled opening, surrounded by  
concentric fibres, leading by a common, short,  
cylindrical duct to the broader cavity, which lat-  
ter is divided by two longitudinal parietes into  
three separate portions. If a tube is introduced  
into the common duct, the air injected will simul-  
taneously fill all three portions of the cavity,  
but if the tube is inserted into any one of the  
three separate portions, the air will fill that par-

ticular portion, leaving the two others collapsed.  
The interior surface of this organ secretes a whit-  
ish mucus. Adjoining the common opening,  
from ten to eleven small rounded glands com-  
mence, arranged on a line towards the pylorus.  
Each gland has, in its centre, a minute wrinkled  
opening, leading into a small cavity secreting  
mucus.

The stomach was extended by the remains  
(heads and legs,) of a prodigious quantity of large  
black ants, inhabiting the hills. The contents of  
the stomach were involved in mucus, deeply tinc-  
tured with bile, and among them appeared five  
small rounded fragments of granite. Another  
individual expired after 10 days' confinement,  
during which period it took no food, although it  
was repeatedly placed among swarms of the black  
and red ants, so excessively numerous in the val-  
ley of Pinang. Water it always took when offer-  
ed, lapping it up with the tongue in the same  
manner that serpents drink.

Costæ veræ 8 pairs; spuræ 7 pairs = 15  
pairs. The ensiform process of the os sternum,  
is greatly elongated, terminating in a broad,  
rounded, thin cartilaginous plate.

## PACHYDERMATA.

### PROBOSCOIDEA.

GEN.—ELEPHAS, *Linne.*

(1133bb.) ELEPHAS INDICUS Linne.

SYN.—“Gajah” of the Malays.

HAB.—*Malayan Peninsula*. India, Burma,  
Siam, Ceylon, Sumatra, Borneo.

Elephants are very numerous on the Malayan  
Peninsula. They may be procured at the follow-  
ing rates:—

“For an elephant	4 ft. 6 ins. high	120 Dollars.
do.	5 „ 3 „.....	200 „
do.	6 „ 0 „.....	220 „
do.	6 „ 9 „.....	400 „
do.	7 „ 6 „.....	420 „

Those exceeding this height are paid for at an  
advance on the last mentioned rate of 20 dollars  
for one foot six inches. If above eight feet and  
three inches, then an addition of 40 dollars for  
each one foot six inches is charged. Elephants  
ten feet six inches in height are taken by the Sia-  
mese to the Capital, and it is not permitted  
to sell them. The Keddah chiefs used formerly  
to breed elephants, a speculation rarely, if ever,  
attempted elsewhere. Coromandel Native Tra-  
ders were, until late years, constantly in the  
habit of loading vessels with elephants for that  
Coast.” (Extract from Lieut. Colonel James  
Low's “*Dissertation*” &c.)

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

"Babi utan" of the Malays of the Peninsula.

HAB.—*Malayan Peninsula, Pinang, Singapore, Luncavy Islands.* Bengal, Nipal, Southern Mahratta Country.

The difference between the Indian and the German wild hog (*Sus Scrofa ferus*, Lin.) have been pointed out by W. Elliot, Esq. (*Madras Journal*, Vol. X. 1839, p. 219.) The colour of the adult is brownish-black, scantily covered with black hairs, of which few retain the infantile yellowish subterminal band. Besides the black recumbent mane of the occiput and back, the whiskers and bristles above and below the eye, there is a bundle of long black bristles on the throat. The hairs of the throat and chest are reversed. The tail is scantily covered with short hairs, the apex compressed, with long lateral bristles, like those of the elephant, arranged like the wings of an arrow. The young is more hairy, with the plurality of hairs tawny or fulvous, some with black root and apex, which, as they are more or less mixed with black hairs, produce on the sides of the body saturated fulvous stripes. The hairs of the throat, chest, abdomen, and elbows, (in the two latter places very long,) are black at the basal, and white at the apical half. Wild hogs are exceedingly numerous on the Peninsula, and most of the Malayan Islands. The largest boar examined measured from the apex of the nose to the root of the tail, five feet; the tail one foot. The stomach of a young boar, examined shortly after it had been speared, was extended with food, principally consisting of the remains of a very large coleopterous larva, some small seeds of different kinds, leaves, grass and roots.

SYN.—*Rhinoceros sondaicus*, Cuvier, } Apud  
"Warak," Badak," } Horsfield.

*Rhinoceros Javanensis*, F. Cuvier, apud Schinz.

HAB.—*Malayan Peninsula.* Java.

This, as well as the former species, appears to be numerous on the Malayan Peninsula.

A two-horned *Rhinoceros* is stated by the Malays to inhabit, but rarely to leave, the densest jungle. The Museum of the Asiatic Society possesses a skull, and also a head with the skin on, of *Rhinoceros Sumatranus*, Raffles, from the Tenasserim Provinces, in which locality the

existence of the species has been recorded by Dr. Helfer and Mr. Blyth. This fact would seem to corroborate the statement of the Malays, and the habitat of *Rhinoceros Sumatranus* may reasonably be expected to be hereafter found to extend over the neighbouring Malayan Peninsula. As such, it has indeed been enumerated by Capt. Begbie, the author of "*Malayan Peninsula*," &c, Madras, 1834. In Lieut. Col. Low's *History of Tenasserim* (Journal Royal Asiatic Society, Vol. 3. 1836,) is figured the head of a young *Rhinoceros*, which, from the considerable protuberance between the eyes, appears to represent a two-horned, probably the present, species.

HAB.—*Malayan Peninsula.* Sumatra, Borneo.

The body of a new born male, found in Province Wellesley in August 1844, was shortly after its death carried over to Pinang. As described by Colonel Farquhar, it was of a beautiful black velvet colour, with purple reflections, with numerous small, and other larger, irregular spots on the body, arranged in longitudinal stripes, above of a rich gamboge, beneath and on the inner side of the extremities, paler yellow. The underlip was white. The shrivelled remains of the black funiculus umbilicalis were upwards of four inches in length. The fur very short, dense, and velvety. The separate hairs, of either of the two prevailing colours, slightly curly.

The animal, from which a sketch was taken on its arrival at Pinang, was the property of the Rev. R. Panting, A. M. The skin, imperfectly preserved, has lately been deposited in the Museum of the Asiatic Society.

On the 16th of May 1845, I obtained a living young female *Tapir*, captured in Keddah a few days previously. Though still in its infantile garb, it was older than the preceding. The ground colour was a brownish-black, like worn-out velvet; the spots, stripes, and the posterior part of the abdomen were of a dirty-white. The separate hairs were longer and curly; the hairy

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

ears retained numerous white spots on the margins and external surface. The lips were blackish, with numerous short distant bristles, which also appeared round the nostrils, on the ridge of the nose, above and below the eyes, on the cheeks and on the throat. Two black mammae were situated between the hind legs, three and a half inches behind the large naked cicatrix of funiculus umbilicalis.

From the first, although fresh from its native wilds, this young Tapir shewed a remarkably gentle disposition. The day time it spent in sleeping in a dark recess of the portico of my house, though it would rouse itself if noticed. Towards sunset it became lively, would bathe, feed, saunter abroad, and with its lengthened nose examine objects in the way. Within a few days after its arrival, it commenced to exhibit a marked partiality to the society of man, not indeed to its keeper in particular, whom it scarcely had discrimination enough to distinguish, but to any body who happened to notice or caress it. Towards sunset, it would follow a servant on the green in front of the house, and punctually imitate his movements, whether standing, walking, or running. If the man suddenly hid himself, the Tapir would hasten to the spot where it had lost sight of its leader, look about in all directions, and, if unsuccessful in discovering him, express its disappointment by a peculiar loud whistling. On the re-appearance of the man, it expressed its pleasure by rubbing its side against his legs, running between them, occasionally giving out a short singular sound, resembling that produced when the larger wood-pickers tap the trees, but more sonorous. When of an evening it heard the voices of people in the verandah above the portico, it exhibited strong marks of impatience, till let loose, when of its own accord it would, awkwardly enough, ascend a flight of stairs leading to the verandah. It would then quietly lie down at their feet, and by stretching its limbs and shaking its head, express the satisfaction it

derived from being caressed; and it was only by compulsion that it could be made to leave the company. Its food consisted of plantains, pine-apples, mangustins, jambu, leaves of *Ficus pipul*, sugar-cane, and boiled rice, of which latter it was particularly fond, if mixed with a little salt. Its drink was water, and also milk and cocoanut oil, which latter taste the Tapir possesses in common with the Orang-utan. It delighted in bathing, and was otherwise cleanly. When roaming about the garden, (its walk was like that of the elephant,) it would select a spot with soft earth, and like a cat form with its hind legs a small excavation, and again cover it. The whole body has a peculiar, and by no means offensive exhalation, somewhat resembling that noted of *Arctictis Binturong*. Indeed, this is so tenacious, that although the skin of the individual above described has been preserved more than a twelvemonth, and kept in a strongly camphorated case, the odour is still perceptible.

On the 27th of June 1845, the subject of the preceding notice expired after two days' illness, from inflammation of the lungs, brought on by the strong southerly winds, prevailing throughout the Straits of Malacca during the season, which in man produces a slight influenza, in animals frequently terminating fatally. The few adult Tapirs, which occasionally have been kept in confinement by residents at Malacca, have acquired the character of being hardy animals. During the short period that the present lived in my possession, no perceptible change appeared in its growth, but a striking alteration took place in its colours. Nearly all the white spots on the head, nape of the neck, and back of the ears, gradually disappeared, and the upper part only of the margin of the ears remained white, which colour it retains in the adult animal. On the posterior part of the back and sides, the black and white stripes were in a state of progressing obliteration, their hairs had faded to a brownish colour, and were about being replaced by a shorter and less dense fur of the fresh white hairs, which were to form the characteristic permanent white mark, already appearing in outline, when death terminated the unfinished process of nature.

Vertebrae; cervical seven, of which the atlas and epistrophæus are the largest; dorsal twenty; lumbar four; sacral seven; caudal three.

Sternum. The anterior extremity cartilaginous, sharply keeled, arched, continued over manubrium, composed of two rounded angularly-joined pieces, as far as the second pair of ribs; corpus composed of five pieces, of which the two posterior, in a pair, are connected by cartilage.

Costæ verae, eight pairs; spuriae, twelve pairs=twenty pairs; the last spurious rib is rudimentary, and absent on the left side.

Femur, five and two-eighth inches long; the large bony sub-trochanteric process, describ-

## MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

ed by Sir Everard Home, is developed, though partly cartilaginous, measuring one inch in length at the base.

Liver of moderate size, each lobe divided into two portions of nearly equal size.

Gall-bladder, none.

Spleen; tongued-shaped, flattened, with cutting margins, seven and a half inches in length, one and six-eighth in breadth.

Pancreas; in a state not to admit of accurate examination.

Kidneys; three and six-eight inches in length; one and six-eighth in breadth.

Renes succenturiati, none. ●

Urinary bladder; very large.

Stomach; capacious. Its dimensions in the state in which it appeared, distended with food, were—

Length along the smaller curvature, 0 ft. 5 $\frac{3}{8}$  ins.

Length along the greater, 1 „ 9 $\frac{1}{8}$  „

Circumference from cardia round

fundus,..... 1 „ 0 „

Circumference round pylorus,..... 0 „ 3 $\frac{1}{2}$  „

The internal surface smooth, villous.

Where the duodenum joins the pylorus, it is considerably widened.

Length of the intestinal canal:

Small Intestines,..... 27 feet 7 inches.

Large,..... 6 „ 4 „

Cæcum, ..... 0 „ 6 „

Average circumference of small, 0 „ 2 $\frac{3}{8}$  „

Do. do. large, ... 0 „ 3 $\frac{1}{2}$  „

Cæcum sacculated, with a longitudinal band on either side. - Distended with fæces as it appeared, the greatest circumference close to the fundus was one foot one and a half inch.

In the adult Tapir dissected by Sir E. Home, and which was according to Mr. Yarrel eight feet in length, the relative proportion between the length of the intestinal canal and that of the body, was as eleven to one. In the present young female, the relative length of the intestinal canal is proportionally less than in the adult, being less than as ten to one.

### SOLIDUNGULA.

GEN.—*EQUUS* Linne.

(1133hh.) *EQUUS CABALLUS*, Linne.

The horse, “Kuda” of the Malays appears not to be indigenous in the Peninsula. The few ponies, which the wealthier use for ordinary purposes, are imported either from Siam, Burma, or Sumatra. The Malays either travel by water, or prefer the elephant as a locomotive more dignified than the horse.

### RUMINANTIA.

GEN.—*MOSCHUS*, Linne

*TRAGULUS*, Brisson.

(1133R.) *TRAGULUS KANCHIL*, Gray; List.

Chevrotain de Java, }  
Javan Musk, Shaw.

*Moschus Palandok*, Marsden.

*Moschus Kanchil*, Raffles.

*Pelandok*, Raffles.

*Moschus fulviventer*, Gray.

“Kanchil” or “Pelandok” of the Malays of the Peninsula.

HAB.—*Singapore, Pinang, Lancary Islands, Malayan Peninsula.* Sumatra, Java.

In some individuals the back is nearly black.

The colour and distribution of the marks of the chest and abdomen are also liable to individual variations, one of which gave rise to the supposed species, *Moschus fulviventer*. The animal is by the Malays indiscriminately denominated “Kanchil”, and “Pelandok;” the latter denomination is sometimes *par excellence* applied to the young, and this circumstance in all probability gave rise to the supposed species *Moschus Pelandok*. The species is astonishingly numerous. In Prince of Wales’ Island, any number may be procured within a short notice, at the rate of one Spanish dollar per dozen. Knowing the partiality of these deer to the leaves of the sweet potato plant (*Convolvulus batatas*), the Malays either use traps, baited with this vegetable, or lie in ambush in moonlight nights in fields where it is cultivated, and disable the intruders by throwing sticks at their legs. In confinement, in its native climate, the animal becomes rather delicate, though it occasionally survives, and even breeds. The female has four mammæ, and one or two young at the time. The new-born measures eight and six-eight inches in length, of which the head is three inches, the tail one inch. The skin of the upper parts is of a pale blackish colour, scantily covered with short, fine, brown hairs. The abdomen and inner side of the limbs are pale yellow; the throat and chest have the dark marks of the adult, but paler. The largest adults measure from the apex of the nose to the root of the tail, one foot six and a half inches; the tail three inches in length.

(1133jj.) *TRAGULUS JAVANICUS*, Pallas.

SYN.—*Moschus Javanicus*, Gmelin.

*Moschus Javanicus*, Pallas, apud Raffles.  
Napu, Raffles.

*Moschus indicus*, Gmelin, } Apud Gray.  
*Cervus Javanicus*, Osbek. }

*Moschus Napu*, Fred. Cuvier.

“Napu” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula.* Sumatra, Java, Borneo.

On the Malayan Peninsula, the species appears to be far less numerous than the preceding. The canines of the female are very small. The four mammæ are situated at the posterior part of the abdomen, a little in front of the hind legs. The anterior pair are half an inch apart; the posterior two-eighths of an inch apart. The two pairs are half an inch distant from each other. In an adult female, measuring from the apex of the

# MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

nose to the root of the tail two feet, four and two-eighth inches; the tail five inches: the intestinal canal was of the following dimensions:

Small Intestines..... 13 feet 6 inches.  
Large ditto..... 7 „ 10 „  
Cæcum..... 0 „ 6 „

The gall-bladder is very large; immediately behind it is situated the right kidney.

“Rusa Bunga” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula, Pinang*. Sumatra, Bengal, Assam, Nipal, Southern Mahratta Country, Ceylon.

Sir Stamford Raffles thinks it probable that the Axis in Sumatra has been introduced from Bengal. It is numerous in Keddah, and at present in Pinang. But it did not inhabit Prince of Wales’ Island till one of the last Governors of the late Presidency took the trouble of importing from Bengal some pairs, which were kept in the park adjoining Government House, (Suffolk House.) When the Presidency of Prince of Wales’ Island was abolished, and with it all its paraphernalia, except the titles of as many of its officers as were necessary to the continuance of H. M. Court of Judicature, the deer of the quondam Governor’s park found their way into the jungle, where they have multiplied to a prodigious extent.

RUSA, Hamilton Smith.

(1133mm.) RUSA EQUINA, Hamilton Smith.

SYN.—Cervus equinus, Cuvier.

Cervus Rusa, Raffles.

Rusa etam or Kumbang, Raffles.

“Rusa” or Rusa etam” of the Malays of the Peninsula.

HAB.—*Malayan Peninsula, Pinang*. Sumatra, Borneo.

The Malayan individuals correspond with the description given by Sir S. Raffles of *Cervus Rusa*. The lips are whitish; the posterior part of the lower, sometimes dark-brown. Round the eyes and the lachrymal sinus, on the side of the forehead, root of the ears, and on the throat, the hairs are either uniformly pale ferruginous, or have a subterminal band of that colour, the effect of which is to impart a pale rusty tint to these parts. Normally, each horn has three antlers, of which the lower or anterior, commencing from the burr, is directed outwards till towards the apex which turns slightly inward. The second and outward turned antler commences at the root of the third, and is the shortest of the three. The third is directed inwards, and is the longest of the three. In the number, direction, and size of the antlers, numerous individual variations occur.

According to Mr. Blyth’s observations, *Cervus Hippelaphus* has, normally, the third antler much longer than the second; *Cervus Aristotelis* has much larger and more divergent horns, of which the second and third antlers are about equal. Considering the similarity of colours and size of *Cervus equinus*, *Hippelaphus*, and *Aristotelis*, Mr. Elliot is probably right in consider-

## MAMMALIA OF MALAYAN PENINSULA AND ISLANDS.

described by Aristotle under the designation of *Hippelaphus*. (*Madras Journal*, 1839, p. 220.), and *Cervus Peronii*, Cuvier—*Cervus* du Timor—may probably be added as a fourth variety.

PANOLIA, Gray : List.

*Note to GEN. NYCTINOMUS*, A male *Nyctinomus bengalensis*, Geoffroy, (*Syn. Vespertilio plicatus*, Buchan.—*N. bengalensis*, Geoffroy, apud Horsfield.—*Dysopes plicatus*, Temminck, apud Schinz,) examined after the Catalogue had passed through the press, exhibited a true cæcum. The entire length of the animal was  $4\frac{3}{8}$  inches, of which the tail measured  $1\frac{5}{8}$  inch. Extent of the flying membrane : 1 foot  $0\frac{4}{8}$  inch.

Length of the small Intestine,..... $9\frac{1}{8}$  inches.

„ „ large ditto,..... $4\frac{1}{8}$  „

„ „ cæcum,..... $0\frac{3}{8}$  „

The cæcum is crescent-shaped, with the concave curvature firmly adhering to the external surface of the small intestine. The convex curvature presents near the apex a sacculated appearance; the membranes are thickened. Where the cæcum joins, the small intestine and the rectum are narrowed.—*Fort William*, Dec. 11th, 1846. *Ben. As. Soc. Journal*, No. CLXXII of 1846.

## (1134) MAMMALIA OF THE SOMALI COUNTRY.

(1135) *Canis variegatus*, Ruppell. “The Somali Jackal.” He carries off kids and lambs, rather disdaining garbage; and unless driven away by dogs, he is capable of doing great damage to the flocks. The Somali call him Dowao.

(1136) *Hyæna crocuta*? (Erxleben), var.? Bright fulvous Hyæna, with dark spots not very distinct, and a black tail-tip: probably of the race termed *H. crocuta rufa* by Fischer, and which Dr. Gray refers to *H. brunnea*, Thunberg (*H. rufa*, Cuv. and *H. fusca*, Geoffroy), (*Note*. This name more probably refers to the specimen

Foss, VII, 318 (4th edit), and which is evidently *H. Villosa*, A. Smith (Lin. Trans. XV, pt, 1, 461) from South Africa (Pt. Natal); but which is not the ‘Strand Wolf’ of the Cape colonists (who term the common Spotted Hyæna the ‘Tiger Wolf’), or *H. Villosa*, A. Smith, which Dr. Gray considers to be a S. African variety of *H. striata*, Zimmerman, the common striped Hyæna of Asia and N. Africa. We have seen *H. villosa* alive, and have minutely compared its skull with skulls of the spotted and of the striped Hyænas; and arrived at the conclusion that it was a distinct species, nearly affined to *H. striata*, but with the solitary true molar less developed, though more so than in *H. crocuta*. Vide also Cuvier, *Oss. Foss* VII, 319 (4th edit.) Dr. Gray even institutes a genus *Crocota*, to which he refers as species *Cr. maculata* (*Canis crocuta*, Erxleben, *Hyæna maculata*, Humb., v. *H. capensis*, Desmarest), the ordinary spotted Hyæna, and *Cr. brunnea* (with synonymes as before cited). The Somali animal is probably the latter. “The Somali call it *Waraba*,” “or *Durwa*.” It is common to all the Somali country, whines about the camp all night, and devours anything it can find during the day, pulling down camels and even children. The natives have many superstitions about this animal, and you often hear of a man being called *Waraba* after his proper name, the idea being that by rubbing certain plants over the body the magician can convert himself like Mars into a Wolf. In the cold season when the *Waraba* is hungry he attacks man. The Somalis all declare this animal

capulated with alternately." (*Vide* Pliny VIII. 30; as cited by Cuvier, *Oss. Foss.* VII. 312, 4th edit.)

(1137) *Mungos fasciatus*; *Herpestes fasciatus*, Desmarest: *Vicerra mungo*, Kämpfer; *V. ichneumon*, Schreber (from Buffon, III, t. 19); *H. Zebra*, Ruppell; *Ryzsena suricata* apud Children, 'Appendix to Clapperton's Travels', called the *kaduf*. "These animals run about in large batches, and defend themselves savagely when wounded. They inhabit the plateau, burrow deep, and when pursued endeavour to escape by hiding themselves: yet with characteristic curiosity, they must peep out of their asylum after a few minutes' concealment."

(1138) *Felis caracal*, Schreber. "Called by the Somalis *Jumbil*. It is principally found in the plains."

(1139) *Xerus rutilus*; *Sciurus rutilus*, Ruppell: *X. brachyotus*, Hemprich and Ehrenberg, apud Gray. "Ground Squirrel, called *Daba-kulla*. It abounds all over the country, burrows especially into deserted ant-hills, and under dead trees. The testes of the male are enormous; and the colour of the coat is glossy and brilliant."

(1140) *Pectinator* (n. g.) *Spekei*, Blyth, n. s. 'Common Rat. Barabduhl. Inhabits stony ground, like the *Hyrax*.' This highly interesting rodent belongs to a peculiar N. African group, of which one species only appears hitherto to be tolerably known, the *Otenodactylus Massonii*, Gray. (*Note.* *Vide* a notice of the anatomy of this animal; by Mr. Yarrell, in *Proc. Zool. Soc.* 1831, p. 49. A second species would seem to exist in the *Mus gundi*, Rothman or *Gandi Marmot* of Pennants. 'Zoology'; which, being described to be of the "size of a small Rabbit," and of a "testaceous-red colour" can scarcely (as remarked by Dr. Gray) be specifically identical with *Ot. Massonii*, even though from the same country, Barbary. The fur of *Ot. Massonii* is pale yellowish-brown; and its tail is described by Mr. Yarrell to be 1 inch long. The *Gundi* is merely stated to have a "short tail." Accordingly, the following (obviously another of the same group and region), with rudimentary tail "but just perceptible to the touch," is probably a third species, which was observed by Captain Lyon in the mountains north of Tripoli. That traveller informs us, that "It much resembles a Guinea-pig in form, but is of a light brown mouse-colour. Fur longer than that of a rat, and very silky; eyes black, large, and prominent. Orifices of ears, which are quite flat against the sides of the head, also black, and free from hair; the tail, or rather a little stump in place of one, is just perceptible by the touch, and from it grows a tuft or bunch of long black hairs. The body is very round and fat, and particularly broad at the shoulders. These animals burrow amongst the rocks. They are eaten with great relish by the natives, and no doubt are very

good, as the flesh is exceedingly white and fat, and resembles that of a Rabbit."—*Travels in Barbary*, page 32.) The animals of this group are clad with delicately soft fur, have very long moustaches, and four toes only on each foot. The palms and soles are naked, the latter to the heel or tarsal joint; and the entire length of the tarse is brought to the ground when walking. Over each claw is a curving tuft of stiffish bristles, more conspicuously developed on the hind-feet; and the innermost toe of the hind-foot has a peculiar combing apparatus, which has been described by Mr. Yarrell in the instance of *Otenodactylus Massonii*. "With this comblike instrument," remarks that naturalist "the little animals were observed [in the London Zoological Garden] to be continually dressing their soft fur; and the facility with which they managed to reach every part of each lateral half with the toe of the foot on that side, as well as the rapidity of the motion, were very remarkable." The muzzle is completely furred; and the rudimentary or short tail is furnished with long hair (as in the *Sciuridæ*). The rodential tusks are narrow and rounded; and in *Otenodactylus* there are only three molars on each side above and below, and which are surrounded with enamel, the upper having one deep indentation externally, the lower being indented on both sides. In our new genus there is a small and simple fourth molar anteriorly above and below: and the next to it above is smaller than the third and fourth, and seems to have no distinct indentation (the molars being, however, much worn away by attrition in the specimen examined). The lower jaw of *Pectinator* is very remarkable for showing no indication even of a coronoid process; a fact not mentioned by Mr. Yarrell in his description of the anatomy of *Otenodactylus*. The condyle is small, and articulates on a level with the crowns of the molars. The auditory bullæ are remarkably large and are seen from above (as in *Chinchilla*.) The antiorbital foramen is large. Palate contracted, narrowing to the front; and the post-palatal emargination is continued forward to a line with the middle of the last molar; externally, *Pectinator* is distinguished from *Otenodactylus* by having the tail and ear-conch well developed; a smaller eye; and apparently a general adaptation for more diurnal and less fossorial habits. The eyes are scarcely so large as in a common Rat. The auricles are broadly ovoid, subnude, with a fringe of whitish hairs on their anterior margin, and a patch of dense whitish fur at base on their outer surface. Length of *P. Spekei*, from nose to base of tail, about 6 inches; and tail probably  $2\frac{1}{4}$  inches; or with hair  $3\frac{1}{4}$  in.; Tars: with toes  $1\frac{3}{8}$  inches. Auricle (measured posteriorly)  $\frac{1}{2}$  in. The skull measures  $1\frac{7}{8}$  in. in length and  $1\frac{1}{8}$  inch in greatest breadth (at the *zygomata* posteriorly); between the orbits somewhat ex-

## MAMMALIA OF SOMALI.

ceeding  $\frac{1}{2}$  inch. Fur, soft and moderately long, of a sandy grey-brown colour, slightly washed with rufous especially on the crown; the basal half of the piles pale dusky: at the *nates*, the fur is more dense and woolly, and rufescent-whitish or pale isabelline: the moustaches are chiefly black, and the longest of them measure about 3 inches; the hairs upon the tail are shorter towards its base, then lengthened as in the Squirrels; these long hairs being of a sullied or isabella white for the basal half, and then black with a white tip: hence, in the living animal, the bushy tail would appear whitish along its middle, with broad black lateral and longitudinal bands, which again are fringed externally with dull white: hairs upon the feet whitish, the tufts or brushes over and impending the kind-claws shewing conspicuously: the combing apparatus of the innermost hind-toe consists of some exceedingly harsh and stiff short bristles immediately impending (but shorter than) the claw, and above these again are some equally short bristles which are not quite so rigid; over which is finally the long incurved tuft of finer bristles, the lower most of which are shorter and more rigid than the upper: on the next toe the same remarkable structure is seen, and more easily felt, but is considerably less developed. This discovery of a second generic form of a peculiar group, hitherto represented only by *Ctenodactylus* (which has long stood quite isolated among other *Rodentia*), will be hailed with some satisfaction by those who have paid attention to the classification of the order, and will tend to remove such doubts as may exist of the propriety of recognising this as a separate family (however limited, according to present knowledge), about equivalent to the Chinchillidæ of South America, to which, upon the whole, the *Pectinatoridæ* would seem to be more nearly affined than to any other known form. It is highly probable, however, that more species and even generic forms remain to be discovered of this peculiarly African family; and that it will prove to be at least as extensive as the *Chinchillidæ*; and perhaps that even *Petromys* should be admitted within its extreme confines. Capt. Lyon's Tripoli animal, with tail reduced to a mere tubercle, is certainly one species which has not yet been scientifically examined; and the *Gundi Marmot* of Pennant is probably another: but these little mouse-coloured rodents seldom attract the attention of unscientific collectors; unless, indeed, it should so happen that their attention had been especially directed to them.

(1141) *Hyrax habessinicus*, Hemprich and Ehrenberg: *Ashkoko* of the Appendix to Bruce's Travels; recognised as a distinct species by Dr. Gray; but referred by Dr. Ruppell to *H. damar*, Cuvier, v. *syriacus* of Schreber. Half-grown specimen. "The Somal call it *Bauni*. It inhabits rocky ground and delights in sunning itself,

## MAMMALIA OF SOMALI.

running about the rocks, and living in cliffs and holes. Neither Lt. Speke nor I ever saw it in the plains. The Arabs here eat it, but the Somal do not."

*Gazelle* —? Heads of male and female, of one of the several species which have been more or less confounded under *G. dorcas*; and quite distinct from the common Aden Gazelle, which is frequently brought alive to Calcutta. One marked peculiarity consists in the ears being of an ash-grey colour, contrasting strongly with the hue of the neck and doubtless also of the body. Horns robust, curved backward and then upward, and diverging but slightly; much longer, and with the annuli wider apart, than in the Aden Gazelle, though the animal would seem to be of the same size. The horns of the female are very much stouter than we have seen in any other female Gazelle, and follow the same curve as in the male, having rudimentary annuli. Muzzle whitish, with a strongly contrasting black nose-patch. The Society possesses a species of Gazelle (habitat uncertain), which much resembles the Aden Gazelle except in being considerably larger, with proportionally longer and more distantly knobbed horns, much as in the present race: but both of these have the ears rufescent and not ashy. At present, we are far from being satisfied with the manner in which Dr. Gray has brought together sundry of these refined races of Gazelle, in the *Proc Zool. Soc.* for June 11th, 1850 (*Ann. Mag. N. H.* VIII, 1851, p. 131). It seems like cutting rather than unravelling of the tangled knot. Lt. Burton writes—"A kind of Gazelle called by the people *Dera*, as you may observe that there is an elevation of loose replicated skin upon the nose. It seems to live during the dry season without water, and affects the desert, not being very shy in presence of man, but avoiding jungle. They are found in flocks."

(1142) *Madoqua saltiana*; *Antelope Saltiana*, Blainville; *A. madoqua*, H. Smith. A beautiful skin of a male; and heads of two other males and of a female. "This little Antelope is called *Sagaro*, by the Somal; *Beni Israel* in Abyssinia; and *Ghazalak* by the Arabs. It abounds throughout the country generally in pairs, and is fond of ravines under hills, the beds of nullahs, and patches of desert vegetation. In the northern Somali country, these Antelopes are caught in snares: elsewhere they are run down on foot, taking half a day on account of their great swiftness. The Jackal (*Canis variegatus*) cannot catch them. They sleep by day under the trees; and in the plains their dung (which becomes peculiarly fetid with a musky odour in the sun) is found in heaps as if they assembled for that purpose." Many animals resort habitually to one place to deposit their dung; among them the Indian Rhinoceros, which in the Rajmahal hills is watched for and shot by the natives at such

## MANGANESE ORES.

places; and we have observed the Indian four-horned Antelope to exhibit the same propensity, when tame and loose in a large enclosure.

(1143) *Oreotragus saltatrix*; *Antilope oreotragus*, Forster: *A. saltatrix*, Boddart. The 'Klip springer' of the Cape colonists. A kind of Antelope called *Alakrut*. They live in the higher ranges of the mountains, only in pairs, and are not unlike the musk-deer in coat. They are by no means shy, seldom flying before the foot-fall is heard. They hop in an awkward manner on the points of the hoof at no great pace or distance at a time. The people of the country prize the venison.—*Mr. Blyth in Beng. As. Soc. Jour. Vol. IV, 1855, specimens sent by Captain Burrton from Somali country.*

(1144) MANAGOOT OR MANGOOSTEEN. *Malay. GARCINIA MANGOSTANA.*

(1145) MANDRAKE PLANT. *ATROPA MANDRAGORA*, Liu.  
Ustrung, ARAB. | Luckmuna, luckmunec,  
Murdumi geca, PERS. | HIND  
Caat-jootie.

The root of this plant was formerly an article of the British Materia Medica. The leaves were till recently employed in preparing anodyne fomentations. The Arabians place the root, which they call Ussul-ul-loofah, amongst their most powerful cathartics, and also suppose it to be of use as an antispasmodic. What of it is found in India is probably brought from Persia or Arabia.—*Ains. Mat. Med. page 26.*

(1146) MANGAI OR MANGOE, the Malayala name of the mango tree which is known throughout India. It grows to a large size, many trees are found three feet in diameter, and thirty feet high. The wood is of a whitish colour, and is not durable or of much value. The natives make canoes of it.—*Edye Mal. and Can.*

(1147) MANGANESE ORES. At the Madras Exhibition of 1857, one very rich ore of manganese was exhibited from Vizianagrum, and another from Bimlipatam.

They occur in huge veins from 3 to 5 feet in thickness, amongst primitive granites, and were forwarded by the Zemindar of Vizianagrum. Some of the blocks weighed from 3 to 4 cwt. They have been very accurately described and carefully analysed by Dr. Scott who mentions that this mineral presents a highly metallic lustre of a bluish black color, interspersed here and there with dull greyish spots, which latter possess the external character of Psilomelan; The sample from Vizianagrum breaks with difficulty and when split with a chisel presents an imperfect rhombohedral cleavage, its sp. gr. is 4.50. When powdered it assumes a dark brownish black color, it dissolves readily in hydrochloric acid with the evolution of chlorine gas, and on evaporation forms a gelatinous mass of a deep yellow color. After a careful

## MARDA MARUM.

analysis the quantitative constitution was found to be as follows:—

Silicic acid, . . . .	8.300	Red oxide of
Peroxide of iron, 12.910		manganese . . . .
Magnesia, . . . . .	2.339	Oxygen, . . . . .
Water and loss, 0.801		1.864

The quantity of metallic manganese in the above analysis amounts to 63.428 per cent, and the total quantity of oxygen combined, therewith to 22.219; it corresponds very closely to the constitution of sesquioxide or of a mixture of protoxide and peroxide. It is protected from oxidation by being a silicate. It agrees most nearly with a manganese ore called marcellin from mount Marcel in Piedmont investigated by Damour. The sample of ore from Bimlipatam was also subjected to a careful quantitative analysis, and was found to differ in containing lime, its composition was as follows:

Silicic acid, . . . .	9.090	Red oxide of man-
Peroxide of iron, 11.720		ganese . . . . .
Lime, . . . . .	1.244	Oxygen, . . . . .
Magnesia, . . . . .	0.668	Water, . . . . .
		Loss, . . . . .
		0.014

It therefore contains metallic manganese 54.929, oxygen 22.558. To constitute a true sesquioxide, 23.904 of oxygen would be required. It would thus appear that the metal is in a lower state of oxidation than in the Vizianagrum specimen. These ores are of little or no commercial value, but they have been found of use in producing strong black, purple, and brown glazes for pottery.—*M. E. J. R.*

## (1148) MANGIFERA OPPOSITIFOLIA.

Mayan, Bur.

Grows wild in most parts of the Burmese country. It is a lofty spreading tree. Fruit, yellow; the size of a plum. There are several varieties, of which some are sweet, and others sour. It is an excellent fruit, but does not grow in the upper provinces.—*Malcom's Travels in South Eastern Asia, Vol. I, p. 179.*

(1149) MANGUIAN, the name applied in Mindoro to the aboriginal tribes occupying the interior of that island.—*Jour. Ind. Arch.*

(1150) MANI was a Persian (temp. Sapore 300 A. D.) he pretended to be the Paraclete promised in John, Chapter 14, &c. and soon established a sect, but was persecuted by Sapore, on which he fled to Eastern Tartary. While here he engaged in drawing and produced a great many extraordinary figures which his followers on his return believed were given to him in heaven, where he informed them he had spent the time during his retreat. His religion is known to Europeans as the Manichean, a mixture of Magian, Hindu, Christian and Mahomedan doctrines and many, even Christian Patriarchs and Bishops, followed him.—*Journ. Ind. Arch. No. 8, Vol. V. August 1851.*

(1151) MARDA or MARTHU or MARTHA marum. *TERMINALIA species?* in Tamil and

## MEHDI OR MUHDEE.

Malayala, and Martha in Canataca, Malabar and Canara, &c.

This tree is of large dimensions and perfectly straight; it is of a dark brown colour and very close-grained, many trees are to be found on the banks of the Maletur river, of a hundred feet long, and about twenty four inches in diameter. From the apparent qualities and native uses of this wood, there is no doubt that it might be converted with advantage into plank, thick-stuff, beams, &c. for ships, where strength is required, and where weight is of little consideration. It runs from sixty-two to seventy pounds the cubic foot, when green: the native carpenters use it with the teak for beams in the pagodas, &c., it is considered durable; and contains a quantity of oil.

The forests in Travancore abound, with trees of this sort which can be obtained on the rivers bank,—an important consideration in the expense of procuring such valuable wood.

There is an inferior description which is named *Villai Marda marum*, *Terminalia Berryii*? or white marda; it much resembles the former tree, excepting in size and in leaf, both of which are considerably smaller, and it is said by the natives to be inferior in quality and durability; it is more like the English oak in grain than any wood Mr. Edye met with. These trees, and also the former sort, are found in patches of some hundreds together, and generally on the banks of rivers.

There is another sort named *Villai Katti Marda*, *Terminalia*, *species*, which is the white marda.—This tree grows to about twelve or fifteen inches in diameter, and twenty-five feet long.

In Malabar, there is another sort, which is well known to the natives by the name of *Kalu Vitte Marda*, and may be considered of the same quality as the last sort. I should have said that this is the dark stone Marda. It is used for the frames of vessels, and many other purposes, for which it is said to answer well.—*Edye, M. and O.*

(1152) **MARUTI**, the Malayala name of a tree which grows to about fourteen inches in diameter, and twenty to twenty-four feet high. It produces a fruit which the natives use as a medicine, and from which also they extract an oil which they use in lamps, and in anointing the body after bathing.—*Edye, M. and O.*

(1153) **MAY A AH**, *Burm.* Is the size of an apple tree. Fruit excellent, size of a plum, purple colour; sweet, small seeds. It is said to grow in the celestial regions, and to be a favourite food of the Nats.—*V. I. p. 180.*

(1154) **MAYAN OR MARIAN**. Burmese, *MANGIFERA OPPOSITIFOLIA*.

(1155) **MEHDI OR MUHDEE**, the twelfth and last Imam, Mohummud surnamed Mehdi; i.e., director and leader, whom the Persians believe to be still alive, and that he will re-appear with

## MICA.

Elias the prophet on the second coming of Jesus Christ.—*Herkt.*

(1156) **MENANGKABITE STATES**. These states lie between Malacca and Salangor, on the one side, and Palhang on the other.—*Journ. Ind. Archipel.*

(1157) **MENISPERMUM HIRSUTUM**.

Roughmood seed, ENG.	Dier hier, dusera tiga,
Menisperme hersute, FR.	INDIAN and CASHM.
Mendsame rancher, GER.	Doosra tiga, TELING.
Frid mull butee, PERS.	

A twining plant, found in most hedges. It flowers during the wet season. The juice of the ripe berries makes a good, durable, blueish purple ink. A decoction of the fresh roots, with a few heads of long pepper, in goat's milk, is administered for rheumatic, and old venereal pains: half a pint every morning is the dose. It is reckoned heating, laxative, and sudorific.

The fresh leaves taste simply herbaceous. Rubbed in water they thicken it into a green jelly, which is sweetened with sugar, and drank when fresh made, to the quantity of half a pint, twice a day for the cure of heat of urine in gonorrhœa. If suffered to stand a few minutes, the gelatinous or mucilaginous parts separate, contract and float in the centre, leaving the water clear like Madeira wine, and almost tasteless. Curry is made of the leaves, for people under a course of the roots, or jelly of the leaves. Goats, cows, and buffaloes eat it.—*Roxburgh's Flora Indica, Vol. III. p.p.814, 15.*

(1158) **MERIAH**. The name given to the human sacrifices in Orissa, where young persons are sacrificed to propitiate the divinity supposed to preside over the soil.

(1159) **ME-YAH**. *Burm. GREWIA.*

(1160) **MICA**, of the Behar Mica Mines. The principal Mica mines of Behar, are situated on the northern face of the Vindhya hills, where the three districts of Behar, Monghyr and Ramghur meet. The most westerly situated mine is thirty-seven miles in a south-easterly direction from Gya, and is in the district of Behar: the most easterly mine is about sixty miles distant in zillah Monghyr, the whole of the intermediate sixty miles being more or less productive of the mineral. The average distance from the Ganges of the whole aggregated group of mines is sixty miles.

Those mines only which lie within the boundary of the district of Behar are worked, those within the district of Monghyr, from some unknown reason, are neither worked nor regarded as of any value by the owners of the estates in which they lie.

The mica reaches the surface in three different states, viz. the good, hard and serviceable mineral; the soft, wet and flimsy mineral; and the chipped and powdered mineral.

The tests as to whether the mica is good for any thing, or whether as the natives say "it is

alice" are its firmness, specific gravity, and the power of reflecting the countenance free of contortions; the latter test we imagine showing the perfect parallelism of its individual plates, and consequent likelihood to split well; the heavier the mineral and the more perfect the reflection, the more valuable is the mineral considered; all the plates not standing the necessary test, are of a soft and flimsy nature without any of the brilliant sparkle of the better sort, the natives call this the "dead mica," and it appears to be in a state of decay.

The plates of the superior kind are used in all the large Gangetic cities and towns, by the native draftsman, whose beautiful productions in body colors, must be familiar to most people: by the lamp and toy makers; by the Mohammedans for ornamenting their Tazials; as well as for ornamenting umbrellahs, boats, and for making artificial flowers.

The second and third kinds are pounded and used for ornamenting toys, pottery, the inside of houses, for sprinkling over clothes and turbans at feasts, the sparkle from which by torch light resembles diamonds; but the great consumption of the inferior mineral takes place during the Hooli festival, during which period the "abeer" or pounded mica mixed with the flour of the small grain, "Koodo" and colored with some red coloring matter, is freely sprinkled over the maddened and intoxicated votaries of those bacchanalian orgies.—CAPT. SHERWILL, *Revenue Surveyor. Beng. As. Soc. Jour. No. IV, of 1851.*

(1161) MIEN-GA. *Burm. Cynometra.*

(1162) MICHELIA CHAMPACA, CHUMPA CHUMPA, HIND. CHAMPACA, RHEED. Champuka or Chumpa, BEN.

Cultivated for its fragrant flowers, it is a beautiful tree, the fruit is not eaten.—*Genl. Med. Top. p. 199.* A pretty large tree common in gardens in most parts of India; flowering time the rainy season; seed ripens in the cold season Roxb.—*Rhode, M. S. S.*

(1163) MILULU, the Malayala name of a tree that grows to about sixteen feet high, and ten inches in diameter. It is known as one of the jungle-woods, and is used by the native carpenters for boats' knees and timbers, on account of its strength.—*Edye, Mal. and Can.*

(1164) MILUM. A glacier in the Himalayas, 8 to 10 miles in length and 3000 feet broad.

(1165) MINAHASSA. Translated for the Journal Ind. Arch. from the Tjdschrift voor Neerlands Indie 7 e. y. 4 e. Deel.

Menado and Kimä, lie directly opposite each other on the West and East sides of the North Eastern peninsula of the large and rich Island of Celebes, have recently, by a resolution of the Netherlands Indian Government, been proclaimed open to foreign trade from the first of next month, and the following

notices of the province of Minahassa in which they lie, will be found interesting. See the resolution at length, Singapore Free Press, 5th October 1848. The preamble declares it to be the desire of the Government to give to the productions, the trade and the shipping of the different possessions of Netherlands India that development for which the condition of each best adapts it, and that this object can be best accomplished, as regards the residency of Menado, by placing it in the immediate, complete and unrestricted enjoyment of the natural advantages which it possesses in its position, fertility of soil, and the industry of its numerous population. It is therefore proclaimed that from the 1st of January 1849, Menado and Kima shall be free ports, where all goods without distinction, and under whatever flag, may be imported free of duty. Vessels are also to be free from tonnage, anchorage or harbour duties. Strangers are to be permitted to reside at the ports for the prosecution of trade.

*General Review.* The capital Menado is situated on a large and beautiful bay on west side of the northerly promontory of Celebes, in 1° 30'. N. Lat. and 124° 56'. East Long. Greenwich, according to the chronometers of the barque Sumatra, (Dec. 1843), according to Horsburgh in 124° 52' East Long. and according to Norrie 125° 0'.

*Cacao.* This product is cultivated in the high lands, but mostly on the coasts. The plantations of it are even now considerable, and this branch of industry only requires not to be impeded by any obstacles, in order to be still further extended. It forms a large ingredient in the trade, and furnishes many petty traders with their daily bread, not to speak of the landowners for whom the cultivation of the cacao affords the only subsistence. The preparation of this product here differs from that in the West Indies, 1,200 to 2,000 piculs of 125 pounds are yearly produced; the prices vary much; being from 50 to 75 florins.

The Sulphur lake Lienong, situated near the negory Lahendong, deserves notice. Half way between Sarongsong and Lahendong, there is observed on the road the sulphur exuding from the ground, and on the left, several sulphureous marshes. Every thing here is barren and rude, and nature waste and inhospitable. From the height at the back of negory Lahendong, is a glorious view. Turning to the west you behold, on both sides of the mountain Korey, the sea in the distance,—on the right, Lakon exposing its full dimensions,—at your feet the negory Lahendong,—at your back lake Lienong about half a mile in circumference, formed by the mountains Tolanko, Lingkoan, Kasuratan,—and Tempusu, below you. The glittering of the waters of the lake beneath is exceedingly beautiful, shewing, from the volcanic action, different colours. On the sides and at your feet

## MINERAL SPRINGS.

you see the sulphur and the hot-water boiling up from the ground, the last at a heat of 200° to 202° fah. so that in two minutes an egg may be boiled in it. Two prahus of hollowed trees bound to each other serve as a raft to reach the other side of the lake, where the aspect of nature is of a more terrific character. Here also the hot water runs from the walls and shore into the lake, but it is of a lower temperature than that on the other side. A boiling sulphur pool, thirty feet in diameter, first arrests attention. It has a temperature of 140. Fah. while all around and under you there is nothing but desolation and boiling water. It is necessary to be careful if you wish to extend your researches further up than the ordinary road. An experienced guide is indispensibly required, as this is the place where the count de Vidua lost his life in his zeal for exploration. Not listening to the advice of the natives around him, he fell into the boiling mud. Ses Tjcl. voor N. I. 5th I. deel I. blz. 306.

The sulphur vapour prevented us from remaining long here. Conducted by persons who knew the country, we observed, over some trees and low underwood, different places where the mud boiled up. It was remarkable that in the circumference of 30 or 40 feet, different degrees of heat were found, 135°, 171°, 145°, and lower, 165°. It was also very remarkable that the volcanic direction near this lake was east and west, and that the earthquakes there are felt in the same direction.

The lake, which is 10 feet deep, has an outlet through the district Sonder, and near the negory Tinji forms one of the most beautiful cascades yet known here.

In the lake Lienong, six different kinds of fish are found, viz, cabos, getegele, sayo lumulontik, komo and the largest kind of eels, and also a number of wild ducks and other water fowl. At noon the thermometer was 75° Fah.—*A Glance at Minahassa. By M. A. F. Van Spreuwenberg. Jour. of the Ind. Arch. Vol. II. No. XII. Dec. 1848, p. 833*

(1166) MINERAL SPRINGS, one of them occurs in the Saugur talook, Nuggur division of Mysore; mentioned by Dr. H. R. Oswald, M. D. *Cat. M. E. of 1857.*

1. *At Darjiling there is a Mineral Water in the Minchu Spring described by B. H. HODGSON, Esq., c. s.* The water is a carbonated and sulphuretted chalybeate spring, containing its iron in the peculiar state in which it is found in the Bath waters.

2. *Mineral Water, from a spring walled in, at Kudjorah in Jessore, from A. GROTE, Esq., c. s.*

This spring is a carbonated, calcareous and magnesian water, with a slight, though probably efficacious proportion of iron, which is of course in the state of carbonate, and held in solution in the water

*Mineral Water from Sosoneah, North of Hueshah from W. H. ELLIOTT, Esq., c. s.*

## MINERAL SPRINGS.

through Mr. GROTE. This water is a carbonated and slightly chalybeate spring, with a little muriate and carbonate of soda also in solution.

(1167) MINTRA. A tribe on the Malay peninsula with numerous superstitions, but believing in another world. The Mintras are not so advanced in cultivation and arts as the Creans of the Tenasserim Coast, these last cultivate cotton, and make their own cloth, which is not the case with the Mintras. The Creans have also many vegetables which are unknown to this tribe. The Mintras clear a small piece of ground in March, in July they set fire to the trees which are then sufficiently dried, and at the beginning of September they plant Paddy, Cludy, &c., their Ladang is so small that their harvest of rice is enough only for a couple of months, the Cludy being then their only food for the remainder of the year. The Mintras are very partial to the flesh of monkeys, and if the use of it was not prohibited by the koran, there is no doubt that the generality of them would have been converted to Islamism. To procure it they use the Sumpitan, which is a Bamboo from 6 to 8 feet long, the arrows are slips of Bamboo 10 inches long, with a piece of light wood at the bottom, shaped to the bore of the tube, which they propel by blowing hard. The point of the arrow being anointed with a prepared poison called Tlipoh, communicates it to the blood and after two or three minutes the animal vomits and falls dead. Should the arrow penetrate the skin of large animals, many of them die, but they are generally lost to the sportsman, as they are able to run, (after having been wounded) to a great distance. These savages seldom miss their aim. I have seen them thus shoot with their arrows monkeys seated on trees of seventy or eighty feet high, when the wounded animal, after jumping on some other branches, and throwing away what he was eating, immediately after fell down, if the Tlipoh had been well prepared.—*Jour. Ind. Arch. Vol. V. No. 8, August 1851.*

(1168) MISWAK, HIND. A twig of a tree used as a tooth brush.

(1169) MOAR, a river of Malacca, which rises in the mountains of Pahang.

(1170) MOHURRUM. This is the first month of the Mohomedan year: the first ten

## MOLLUSCA.

days of this month are held as a festival, which is celebrated as Christmas is, sometimes by strict religious rites or by great festivity according to the opinions or ignorance of the sects. The Shiah Mahomedans and learned Mahomedans generally are most strict in the observance of their religious duties for the first thirteen days of this month.

(1171) MOLUCCAS. The Moluccas exhibit a very singular feature in the exact conical form, with which most of them rise above the horizon to meet the navigator at the distance of 80 or 90 miles. In other cases he is glad to have the flying contour of a landscape to guide him in the recognition of the coast and headlands, but there is something so peculiar in the aspect of these islands, that he feels confident he never can mistake them. The extirpation by the Dutch of the spice trees in the Moluccas is no longer prosecuted, although its effects are of course still felt. The monopoly of the spices is continued, but the system now pursued is not so oppressive to the natives.—*Jour. Ind. Arch. Vol. VI, No. X.*

(1172) MOLLUSCA. Conchology is that branch of science which teaches the structure and forms of the shells which are the hard external covering of the animals belonging to the class *Mollusca*. Although these shells present great variety of forms, and are variously marked, they are only a subsidiary part of the structure of the animals to which they belong. Hence amongst naturalists the shells are only studied in connection with the structure of the animals which inhabit them. The Mollusca are arranged into Divisions, Classes, Orders, Families, Genera and sub-Genera, the two great divisions, the Encephala and Acephala, being sub-divided into 6 classes as follows:

Encephala.	Acephala.
1. Cephalopoda.	4. Brachiopoda.
2. Gasteropoda.	5. Conchifera.
3. Pteropoda.	6. Tunicata.

Amongst the various paths which the researches of naturalists incline them to pursue, there are few which have been more frequently entered on than the Mollusca of these countries. But in their treatment of them naturalists have hitherto only described the shells of particular localities, and this article may be regarded as the result of the first attempt which has been made to bring together from every known available source the names of the genera and species of the mollusca of Eastern and Southern Asia. The classification followed is that of Mr. Woodward in his invaluable work on Recent and Fossil shells, and the sources of information have been the Journal of the Asiatic Society of Bengal: the Journal of the Archipelago; the Catalogue of the Government Central Museum, Madras; the Catalogue of the British Museum and tabular classification of

# MOLLUSCA.

the Mollusca arranged by the Editor from Mr. Woodward's work and printed in 1854. The results here given will comprise the Genera known to inhabit the regions to the natural and manufactured products of which our labours relate, stating the number of species in the world belonging to each genus and describing, as many of the species as we have found described. Doubtless, this first attempt will be imperfect, but its improvement will be easy in the future.

## CLASS I.

### CEPHALOPODA. CEPHALOPODS.

#### Order I. Dibranchiata. Section. A. Octopoda. Family I. Argonautidæ.

Genus. Argonauta, Argonaut or paper sailor ; recent 4 sp., fossil, 1 sp. *Syn.* Ocythoe. Nautilus

Nassa.	Labuan.

A variable tendency does not prevail in all shells though some kinds are very liable to it, particularly the genus *Nassa*. In illustration of this property of change, Dr. Traill describes a species of *Nassa* found in the mud of salt swamps in Singapore, it is in colour a dark brown or black, about an inch and a half in length, the outer whorl is smooth, those next the apex of the spire are furrowed longitudinally, and it possesses the usual generic mark of a prominent plait at the upper part of the aperture. Out of many specimens examined, he observed none to deviate from the above description. In the same localities may be found another shell quite similar to the other in form and colour, but not more than half its length, possessing however all the marks of a full grown shell, and as no shells of intermediate size are to be met with, there seems good reason to believe them two distinct species. The following instance is however more remarkable in connexion with the above. He found at Malacca a species of *Nassa* of a pale flesh colour, barred with brown, about a third of an inch in length, and little more than a grain in weight. In the same neighbourhood he met with another specimen, three quarters of an inch in length, and weighing between four and five grains. As in the former case, the two shells were exactly similar in shape and colour, though very different in size and weight, and as both had the marks of having attained their full size, he was ready to believe that he had obtained two new species; a further search however, put him in possession of fifteen additional specimens, similarly marked but all of them intermediate to the two first in size and weight; in fact the whole seventeen formed an almost imperceptible scale of gradation, sufficiently proving that they were so many varieties of one and the same species. He observed several kinds of *Nassa* particularly abundant in the neighbourhood of the Fish Markets, where they may be seen in numbers feeding on dead fish and other animal food. This artificial mode of subsistence is possibly one cause of their

## MOLLUSCA.

variable form and size as it is well known that domestic animals, and others that are more or less dependent on man for their support, are very apt to produce a progeny differing more or less from the parent stock. A good example of the propagation of an accidental variety, is familiar in the instance of a well known domestic animal of the feline genus, which in Singapore is rarely seen with a perfect tail. In the neighbourhood of Fish Markets may also be seen multitudes of dead shells of all sizes some so minute as to be microscopic, and all tenanted by the Paguri or Hermit crabs, as varied in size as the shells they inhabit, and like the Nassa, busily engaged in devouring fragments of dead fish, which is their principal food. The mention of them here is a parallel instance of the effect of artificial life upon some of the lower animals, for these crabs are not, as might be supposed, one, or at most, two or three, species in different stages of growth. If an examination be made, it will be found that individuals of all sizes are laden with spawn, not excepting such as are so minute that their forms are not to be distinguished by the naked eye: it cannot be imagined that each of these is a different species, they are in fact an evident instance of the alteration of a species into an almost infinite number of varieties.

Planaxis sulcatus Ceylon.

*Magilus antiquus* has lately been found north of Penang in the neighbourhood of Junk Ceylon, the natives set some value on them, and occasionally wear them as ornaments; the shell is singular and apt to be mistaken for a petrification, being dense in structure, diaphanous and much like alabaster. It has been often figured and described by naturalists, but the animal inhabiting it is, Dr. Traill believes, unknown, unless described in some very recent publications: it is supposed to be a Gasteropod, though this is rather doubtful, as the shell is said to be generally found imbedded in coral or madrepora: It is probable that this point might be satisfactorily settled by a careful examination of the above locality.

(1173) *Cypræa tigris*, of the very numerous genus of "*Cypræa*," or the "Cowry" shell, the largest species found in Singapore is the "*Cypræa tigris*" which is prettily spotted with black, it is frequently made into snuff boxes in England, the animals of several have been described and figured by authors. The mantle is so large as to cover all the shell, on the back of which there is often a longitudinal line which marks where its two-folds meet: this membrane continually secretes an abundance of viscid fluid which lubricates the shell, and preserves the beautiful polish which has procured for them the name of porcelain shells.

(1174) *Cypræa olivacea* is the most abundant of the Singapore Cowries being found on most beaches under flat stones: it is of the size and much the colour of an olive except that the back is generally mottled with brown and the mouth somewhat yellow; a specimen which Dr. Traill, found with the young attached, was fixed in the usual manner, to the lower surface of a stone: on raising it there was found adhering to it, a flat circular membrane broader than the shell, transparent, and dotted with minute grey spots like grains of sand, on placing the substance in a glass of sea water, numbers of the grains dropped out of the membranaceous mass to the bottom of the glass and immediately assumed rapid and lively movements, some revolving in a rotatory manner, others alternately rising and sinking in the water or sporting over its surface. On a closer examination these grains were seen to be in reality shells, some hundreds in number, nearly transparent, having no perceptible columella and apparently consisting of a single coil or whorl, aperture round, breadth of the shell greater than the length, so that, when on a plain surface it rested on either end like a *Planorbis* or *Nautilus*, the animal effected these rapid movements by the alternate contraction and expansion of its foot which was broad and expand-

## MOLLUSCA.

ed and much larger than the shell, into which it seemed to have no power of withdrawing it.

(1175) *Cypræa*, species, another small Cowry is occasionally found on the Singapore coast, resembling in colour the *C. adusta*, but not more than half the size and less cylindrical in shape: Captain Congalton of the H. C. Steamer "Hooghly" sent one that was fished up in "ten fathom water near Sultan's Shoal to the westward of Singapore, that shell was partially imbedded in a species of sponge, on detaching it from which, Dr. Traill found the cavity of the spongy mass lined with the young fry of the *Cypræa*, differing however in several respects from that of the *C. olivacea*;—instead of being contained in one membranaceous envelope there were above two hundred transparent sacs not larger than grains of mustard seed and each containing about 30 shells so minute that they could not be distinguished without the aid of a microscope, at a moderate computation there could not have been less than six thousand young shells: the difference in size is remarkable as the *Cypræa olivacea* which had the largest offspring is a much smaller shell than the one Dr. Traill had under consideration: in this case he had not an opportunity of studying their habits, &c. as the animals were dead, having been many hours out of the water; when examined under a microscope the shape of the shell was found to resemble exactly that of the young *C. olivacea* above described,

<i>Sub-genus. (Machroschisma). rec.</i>	
<i>Emarginula. rec. 25 sp. fossil, 40 sp.</i>	
<i>Parmopheorus. rec. 10 sp. fossil, 3 sp.</i>	

The *Parmaphora* or Ducks bill Limpet is found in Singapore though by no means a common shell, it is like a *Patella* flattened and elongated, the anterior edge always widely notched, apex slightly recurved, length from one to two inches, colour white; the body of the animal is much more bulky than the shell, and the mantle is so capacious that it covers the whole shell except the apex, which enables it in some degree to elude search, as it appears more like a pulpy or spongy mass than a shell; when touched, the mantle stains the hand a dark purple colour.

### Family XII. Calyptræidæ. Bonnet-limpets.

<i>Helix lævis</i> .	Ceylon.
<i>Helix lineata</i> .	East Indies.

Notes on the Rev. F. Mason's Paper "On the Shells of the Tenasserim Provinces." By W. H. Benson, Esq. Communicated by Dr. T. Cantor. —Beng. As. Soc. Jour. No. CC. February, 1849.

(1176) *Helix Tricumbens*, Gould. This is *Helix delibrata*, Benson, (*Journal Asiatic Society*, 1836.)

(1177) *Helix Anceps*. This shell differs from *Helix serrula*, Benson, in its more depressed spire and flatter apex, its less developed sculpture, comparatively smooth periphery, contabu-

# MOLLUSCA.

late whorls, and larger size with the same number of whorls. There is merely a perforation also, instead of an umbilicus. It is quite distinct and a good species, though of the same group as *H. serrula*.

(1178) *Helix Honesta*. This shell is at once distinguished from *Nanina vesicula*, Benson, by the angularity of the lost whorls, a character not so observable in *N. vesicula*.

(1179) *Helix Saturnia*. Gould. This shell is not contained in Pfeiffer's Monograph. The whorls are too few for it to agree with *H. chevalieri*, (Souleyet) and in that particular and in size it agrees better with *H. oxytes*, Benson, which may stray down thus far from the north, as well as *H. delibrata*. Without fuller characters however, it is impossible to determine.

(1180) *Helix "Zubata"*, Gould, is clearly a misprint for *H. gabata*.

(1181) *Helix Retrorsa*, (not *retorsa*.) Gould, proves to be distinct from *H. interrupta*, Benson, and *H. himalayana*, Lea. The formation of the umbilicus is peculiar. Tenasserim Provinces.

*Helix oraytes*. Benson. Naclai

*Helix textina*. Benson. Henzadda.

*Helix Laidlayana*. Benson. Tributary Mehals (2sp)

*Helix interrupta*. Ben-

son. Calcutta.

*Helix sculpturita*. B. Ava.

*Helix Bolus*. B. Thait-mio.

*Helix rotatoria*. V. de

Bush. Akontong on Irawaddi.

*Helix artificiosa*. Bens. Tenasserim, Valley.

*Helix achatina* Gray. Moulmein.

*Helix tuparia*. Benson. Teria Ghat.

*Helix Merguiensis*. Phillips. Moulmein.

*Helix climacterica*. Benson. Teria Ghat.

*Helix plectostoma*. Benson. Teria ghat.

*Helix serrula*. Benson. Teria Ghat. (3sp.)

*Helix similis*. Fer. Dacca.

*Helix honesta*. Gould. Moulmein.

1. *H. Oldhami*, B.—Ava. Procured by Mr. Oldham.

2. *H. sculpturita*, B.—Ava. What appears to be a small variety of the same shell occurs at Thait-mio, and nearly approaches *H. similis*, Fer. in aspect, though larger.

3. *H. bolus*, B.—Thait-mio. Very abundant at Thait-mio, Prome, Henzada, &c.

4. *H. pauxillula*, B.—Thait-mio, where this minute helix is rare.

5. *H. mensula*, B.—Thait-mio, Rare.

6. *H. hariola*, B.—Thait-mio, Rather rare. Inhabits Acacia trees in Jungle.

7. *H. petita*, B.—Thait-mio. Rare.

8. *H. refuga*, Gould.—Thait-mio. and Akowtong. Not very rare.

9. *H. pausa*, B.—Akowtong. Not common. Found in gardens on Arca Palms, &c.

## MOLLUSCA.

## MOLLUSCA.

10. *H. rotatoria*, V. de Busch.—Akowtong. Very common, found in company with the last. This shell is rarely distinguishable from the Sylhet *H. tapeiria*, B. By the aid of a lens however the sculpture is found to be more ornate and flexuous, whilst in the latter it is simply striate.

11. *H. textrina*, B.—Henzada. Common in jungle. The adult shell has a very handsome pellucid appearance. In the rains the foot is too large for immediate retraction.

12. *H. molecula*, B.—Rangoon. This little species abounds on the Great Pagoda.

13. *H. achatina*, Gray.—Maulmein. Very abundant.

14. *H. bombax*, B.—Maulmein. Rather rare.

15. *H. honesta*, Gould.—Maulmein. Tenasserim valley. Rather common.

16. *H. Merguiensis*, Phillippi—Maulmein, Tenasserim valley. Common. Seems a var. of the next species.

17. *H. Gabata*, Gould.—Maulmein. Mergui. Common.

18. *H. capessens*, B.—Maulmein. Not very rare.

19. *H. infrendens*, B.—Maulmein. Not very rare.

20. *H. Pylaica*, B.—Maulmein. Not uncommon. This curious little shell resembles the American *H. hirsuta*.

21. *H. catinus*, B.—Maulmein. Very rare.

22. *H. cassidula*, B.—Maulmein. Rare.

23. *H. delibrata*, B. (*H. procumbens*, Gould)—Maulmein. Tenasserim valley. No where common. This species has a very wide range, being also found near Cherra.

24. *H. refuga*, var. *dextrorsa*.—Phaiethan. This dextral var. was only met with at one spot in the Tenasserim valley, where it was not rare; it is curious that *H. refuga* does not occur in the valley, but was first seen at Akowtong.

25. *H. castra*, B.—Pija. Rare. A single specimen of this Darjiling shell was found at Pija between Tavoy and Mergui.

26. *H. attegaia*, B.—Phaiethan. Not common.

27. *H. arx*, B.—Therabuin Hill. Rare. This hill has afforded many singular forms, no where else met with.

28. *H. convallata*, B.—Therabuin Hill. Rare. Another singular shell also met with near Pija on the coast between Mergui and Tavoy.

29. *H. biforcata*, B.—Therabuin Hill. A most singular shell, of which but one adult specimen was procured.

30. *H. ceryx*, B.—Phaiethan Hill. Rare.

31. *H. artificiosa*, B.—Phaiethan. Not Rare, but nowhere else found.

32. *H. causia*, B.—Phaiethan. Rare.

33. *H. forabilis*, B.—Phaiethan. Very rare.

34. *H. perpaula*, B.—Phaiethan. Very rare.

35. *H. levicula*, B.—Phaiethan. Rare.

36. *H. petasus*, B.—Phaiethan. Not rare.

37. *H. precaria*, B.—Phaiethan. Very rare.

38. *H. Saturnia*, Gould.—Tenasserim valley. Rare.

39. *H. anceps*, Gould.—Tenasserim valley. Common.

40. *H. retrorsa*, Gould.—Tenasserim valley. Common.

41. *H. acerra*, B.—Mergui. Common.

42. *H. resplendens*, Phillippi—Tenasserim valley.

43. *H. Theodori*, Phillippi—Yanglaw. Very rare.

*Nanina*. *Helix*. (*nanina*.) *Pegu*.

(1182) *Nanina Nana*.

Shell rather small, convex-conoidal, pale  
brownish; whorls six to seven, closely convolut-  
ed, the last rounded; aperture rather wide; lip  
simple; umbilicus evanescent; apex very obtuse.  
Lat. 0.1 poll.

*Helix nana*, *Hutton, Jour. As. Soc. vii. 212.*  
pt. 1.

*Pfr. Mon. Helic. i. 31.*

*Hab.* Simla, Himalaya.

(1183) *Nanina Cacuminifera*.

Shell with a covered umbilicus, conic, trochi-  
form, horn-coloured; spire attenuated towards  
the blunt, nipple-shaped apex; whorls eight,  
slowly increasing, flattened above and marked  
with seven spiral, minutely granulate lines, with  
more minute similar intermediate ones; last whorl  
acutely compressed and keeled, convex, polished  
and with radiating striae beneath; aperture secu-  
riform; peristome sharp, with the lip scarcely di-  
lated and reflected above. Height 10, greatest  
breadth 19, least breadth 16 mill.

*Helix cacuminifera*, *Benson, in Ann. and Mag.*  
*Nat. Hist. 1850, arch, 214.*

*Reere, n. 744. t. 124.*

*Pfr. Mon. Suppl. 36.*

*Hab.* Neilgherries, (*Jerdon*).

(1184) *Nanina Fastigiata*.

Shell imperforate, elevate-conic, very thin, near-  
ly smooth, little shining, pellucid, whitish horn-  
coloured; spire conic; apex rather pointed; su-  
ture impressed, bordered; whorls seven, moderate-  
ly convex, the last acutely keeled, not descend-  
ing anteriorly, rather flat beneath and impressed  
in the centre; aperture nearly perpendicular, de-  
pressed, somewhat quadrangular; peristome sim-  
ple, straight, with the margins almost parallel;  
columellar margin short, callous. Height  $4\frac{1}{3}$ ,  
breadth 4 mill. (*Pfr.*)

*Helix fastigiata*, *Hutton, Journ. As. Soc. vii.*  
217, pt. 1.

*Weigm. Arch. 1839, ii. 222.*

15. 16; *Mon Suppl. 40.*

## MOLLUSCA.

*Hab.* Simla, Himalaya.

(1185) *Nanina vesicula*.

Shell perforate, conoidal-depressed, thin, near-  
ly smooth, shining, translucent, pale horn-colour-  
ed; spire short, conoidal, with the apex acumi-  
nate; suture deep; whorls six, the last one round-  
ed, not descending, convex beneath; aperture near-  
ly perpendicular, lunate-rounded, of equal height  
and breadth; peristome simple, sharp, with the  
columellar margin perpendicular, reflected into  
a short, triangular lamina near the perforation.  
Height  $7\frac{1}{2}$ , greatest breadth 15, least breadth  
13. mill. (*Pfr.*)

*Hab.* Himalaya Mountains.

(1186) *Nanina orcula*.

Shell scarcely perforate, conic-globular, thin,  
with irregular rib-like striae, rough, horn-colour-  
ed, translucent; spire obtusely conic; suture  
deep; whorls three and a half, rounded, the last  
imperceptibly descending; aperture very oblique,  
lunate-roundish; peristome simple, straight, with  
the margins somewhat convergent; columellar  
margin a little reflected, half covering the per-  
foration. Height  $1\frac{3}{4}$ , breadth 2 mill. (*Pfr.*)

*Hab.* Bengal and Bahar, India.

(1187) *Nanina Bimaensis*.

Shell subperforate, obtusely conoidal, oblique-  
ly striate, quite milk-white; spire elevated, with  
the apex blunt, polished; whorls six and a half,  
flattened, not shining beneath; aperture round-  
ish trapeziform; peristome simple, sharp; colu-  
mellar margin reflected at its insertion, almost  
covering the perforation. Height 31, greatest  
breadth 32, least breadth 29 mill. (*M.*)

*Helix Bimaensis*, *Pfr. Mon. Suppl. 45.*

*Hab.* Island of Bimah (*Zollinger*).

(1188) *Nanina rareguttata*.

Shell subperforate, orbicularly conoidal, striat-  
ed, nearly smooth, yellow, conspersed with scarce-  
ly elongated oily spots; whorls five and a half,  
enlarging rapidly, moderately convex, the last  
somewhat inflated, declivous above, convex be-  
neath, uniform or with a single brownish band;  
spire short, with the apex diaphanous; aperture  
large, obliquely roundish-lunate, flesh-coloured  
within; peristome simple, straight; columellar  
margin sharp, reflected at its insertion. Height  
26, greatest breadth 32, least breadth 26.55 mill.

(1190) *Nanina Zecythis*.

Shell scarcely perforate, conoidal-depressed, thin, nearly smooth, shining, translucent, pale reddish horn-coloured, variegated with paler spots; spire short, conoidal, rather acuminate; suture moderate; whorls six, very little convex, the last one broader, not descending, rather flattened beneath; aperture nearly perpendicular, broadly lunate, its breadth surpassing its height; peristome simple, sharp, with the columellar margin arcuate, somewhat declivous, very shortly reflected above. Height 7, greatest breadth 13, least breadth  $10\frac{1}{2}$  mill. (*Pfr.*)

*Helix Zecythis, Benson in Ann. & Mag. N. H. 1852, May, 406. Pfr. Ic. n. 936 t. 143. f. 12-14; Mon. Suppl. 47.*

Larger, with the spire more raised and seven whorls. Height 9, breadth 15 mill. (*Pfr. Ic. t. 143. f. 15.*)

*Hab. Rajmahal Hills, India (Bacon.)*

(1191) *Nanina subjecta*.

Shell perforate, conoidally depressed, thin, striated, oily shining, diaphanous, horn-coloured; spire shortly conoidal, rather pointed; suture slight, whitish; whorls six and a half, very little convex, the last broad, somewhat depressed, not descending, little convex beneath; aperture not very oblique, roundish-lunate, broader than high; peristome simple, straight, columellar margin slightly receding, arched, very shortly reflected above. Height 9, greatest breadth 17, least breadth 14 mill. (*Pfr.*)

*Helix spreta, Benson MSS. olim, not Adams.*
